Bideford.—The annual report of the Medical Officer of Health for Bideford shows that the death-rate exceeded that of 1899, being 16·4 per thousand, which includes persons dying within the borough but actually belonging to the outside district. Those deaths have been much above the average. Infant mortality was less than for the previous three years, the rate being 111·1 per thousand. In this connection, printed "Hints to Mothers for the Feeding of Infants" were being circulated. Persons between the ages of one and five suffered most this year, nearly half the deaths being due to measles and whooping-cough. Comparatively few children had succumbed to chest affections. The zymotic death-rate was a little lower than the previous year—2·4 against 2·9; this included deaths from diarrhœa. Notifications for the year were:—Enteric fever, 6; erysipelas, 8; puerperal fever, 2; measles, 372; the majority of the cases were of a mild type. The infectious diseases hospital was not required during the year. During January, 1900, influenza caused much sickness; May was remarkable for a low death-rate—7·3 per 1000. Measles continued more or less until the end of August. In November and December the death-rate was much below the average. The Sanitary Inspector inspected 773 houses, finding 110 defective; 16 new houses were erected and 20 cottages renovated; 18 houses were disinfected and limewashed. The total number of nuisances abated was 107. Ten houses were condemned; scavenging had been effective; dairies and cowsheds were frequently inspected and nine samples of milk analysed, all being of good quality; slaughter-houses were periodically inspected. The public slaughter-house did not receive the patronage it deserved. Two seizures of unsound meat were made. Dr. Gooding suggested that the Authority should get into closer touch with the vendors of milk, and mentioned the plan of issuing certificates or licences, and publishing a list of those dairy farms that subjected themselves to inspection. This would be some guarantee to the public for the purity of the milk and the cleanliness of the premises. The Medical Officer

referred to the intermittent water supply during the summer. He said that to the best of his knowledge no actual want of water occurred. The quality of the water remained good throughout the year. The total rainfall was 39·3 inches, as against 38·18 inches in 1899.

Crook.—The annual report of Dr. Mackay, Medical Officer, Crook Urban District Council, states that during the year there were 376 births and 200 deaths. There is a decrease in the infant mortality. In dealing with sanitation the Medical Officer says the diminution of diseases due to insanitary surroundings is doubtless owing to the climatic conditions, and not to any marked improvement in the sanitary condition of the district. Amongst the sanitary requirements the Medical Officer points out are the abolition of midden privies, an isolation hospital, and public slaughter-houses.

Hartismere.—The annual report of Dr. E. G. Barnes upon the sanitary condition of the Hartismere rural district is a pretentious pamphlet, comprising some twenty pages of reading matter. Statistics relating to births and deaths are given *in extenso* in elaborate tables, giving comparisons for the past ten years. Last year 260 births were registered in the district, being at the rate of 20·6 per 1000 of the population. The rates in former years were:—1895-9, 23·6; 1890-94, 28·0; 1885-89, 29·8; 1880-84, 32·2;1870-79, 31·3. The decline in the averages appears to indicate that the younger adult population has probably undergone a very considerable decrease from migration to more populous centres. The coming census will determine whether this opinion is well founded or not. The birth-rate in the district is considerably below the general birth-rate for England and Wales, which was 28·9 in 1900. The number of marriages, which has shown a decided decrease in recent years, increased in 1898 and 1899. The returns for 1900 are not yet complete. The figures for the previous five years are:—1899, 104; 1898, 95; 1897, 77; 1896, 82; 1895, 76. The Registrar-General has repeatedly pointed out that a high or low marriage-rate bears a close correspondence with the prosperity or want of prosperity of the country. The number of persons married in the Hartismere rural and Eye urban districts during the ten years 1889-98 was at the rate of 11·9 per 1000 annually, which is much below the corresponding rate for England and Wales—15·6 per 1000. As regards deaths, the total in the district was 171, being 13·6 per 1000. The rates in former years were:—1895-9, 14·4; 1890-94, 17·1; 1885-89, 15·7; 1880-84, 16·0; 1870-79, 18·0. The mortality of children under one year of age was 21 per cent. of the total deaths and 13·8 per cent. of the registered births. This rate is somewhat excessive in comparison with former years. Zymotic diseases have shown a very satisfactory decrease in the district during the last five years. Scarlet fever was less prevalent than usual; eleven cases occurred in the Botesdale Division, four in the Medlesham Division, and one in the Eye division. Diphtheria prevailed to a small extent in the Eye and Botesdale divisions, whilst thirteen cases of erysipelas were reported throughout the district. The work of systematic inspection and nuisance removal has been carried on as in former years, and the sanitary state of the district is well maintained. No fewer than 253 notices were given for sanitary improvements. Dr. Barnes made chemical analyses of seventeen specimens of drinking water, and reported seven "unfit" for drinking or domestic uses, the result of which was that thirty-six houses during the year received an improved supply of water. Attention is called to the fact that the water supply at Wickham Skeith is defective, fifteen houses in the street, near the Swan Inn, being without any satisfactory supply; but at last there seems reason to believe that a suitable site for a public well has been secured, and that the work will shortly be commenced. The number of cases of infectious diseases notified during the year was 39. As regards vaccination, the following paragraph from last year's report still holds true. Dr. Barnes says:—"The working of the new Vaccination Act has resulted in more children being vaccinated than under the old Act, the number of parents availing themselves of the so-called 'Conscience Clause' being small. The provision of calf lymph and the operation being done at home have both contributed to the successful working of the Act."

Irvine.—The Medical Officer for the burgh of Irvine has submitted his annual report for the year just ended. In 1900 there had been 193 deaths, which gave an annual mortality at the rate of 21·35 per thousand of the estimated population. The death-rate for the previous twelve months was 18·47, which shows an increased mortality of 2·88 per 1000 for 1900. Last year's death roll also exceeds that of 1899 by 66 deaths. There was, however, the doctor stated he was glad to be able to say, a decrease in the number of cases of infectious disease in Irvine, only 90 cases being notified last year, as compared with 143 for 1899. As usual, scarlet fever was the most prevalent, there being 57 cases, or 63 per cent. of the whole number of infectious cases notified. Forty scarlet fever cases had been treated in the hospital, as well as twelve cases of enteric and three of diphtheria. There had been a few deaths from scarlet fever. In 1900 92 marriages had been registered, as compared with 71 in 1899.

(INCORPORATED).

OFFICIAL TRANSACTIONS.

"THE CLEANSING OF CESSPOOLS."

(*Concluded from page* 267).

A NEW METHOD.

The method I refer to in the following sections is one which I have had experience in the working of, and is known as "the Bexley system," the makers being Messrs. George Waller and Co.

The system is the "essence of simplicity," no skilled labour being required, and it certainly has a superiority over the old-fashioned mode explained in a preceding section. By this process cesspools can be emptied cheaply, quickly, and inoffensively, and this by daylight. As it will be seen from the statistics, a large number of cesspools can be emptied, and though the carts were continually through the streets, no complaints were received.

DESCRIPTION OF PLANT AND COST.

Carts.—Either two or four-wheel vans can be purchased. The two-wheel vans hold 250 and 300 gallons, and the four-wheel vans 300 and 480 gallons.

I consider the two-wheel vans are the most suitable for general purposes, as they are more readily drawn on to the land, though for a flat district a four-wheel van might prove economical, and these possess the advantage of being converted into a serviceable street watering van at a low cost if required.

The carts and vans are built of wrought iron, and made air-tight with air vessel attached to expel the air from the van during the pumping process. Each van or cart is fitted with cast iron bend and union with cap to take delivery hose, discharge valve and hose for distribution of sewage on the land, and the usual manhole or flap.

Pump.—The pump is made with one barrel, and flange unions for the hose, fitted with cap, being specially designed by the makers to go through narrow passages. The pump has no loose parts, the valve covers having hinged bolts. The valves are simple, and

quickly replaced by the man in charge. The pump will readily throw to a depth of 26ft.

Hose.—The delivery hose is made from best oak-bark tanned English butts, well dressed, the punching and riveting being accurately and carefully done—2¾in. bore.

Leather is undoubtedly the best material for the hose, as the wearing qualities are unsurpassed.

The hose, after rough usage (owing to the critical position of certain cesspools, and the wear and tear incidental to cesspool work), has proved itself to be economical.

The hose is supplied in suitable lengths of 20ft., 40ft., and 60ft., each length having gun-metal screw unions, with "quick" round thread.

If, through pressure of work—as is likely to occur during the wet seasons—the cleansing and oiling of the hose be neglected, and it become dry and hard, in such a case it should be well soaked in warm water before being oiled.

The suction hose is made of best vulcanised rubber, fitted with steel spiral wire, embedded smooth bore, and is armoured on the outside with steel wire.

I am not in a position to give the exact outlay that is necessary for a Local Authority wishing to adopt such a scheme, as the requirements of the locality would have to be taken into consideration, together with the description of the plant; but, as a rough guide for members, an expenditure of from £100 to £250 would meet the requirements of almost any district.

PROCESS OF WORKING.

Sulphate of iron crystals are used to act as a suitable deodorant in subduing any odour that may arise from the cesspool. One hundredweight diluted with 48 gallons of water is well boiled in a portable copper, and 1 gallon of the solution afterwards is used to about 450 gallons of sewage; or 1 lb. of manganate of soda mixed in an iron bucket of water until dissolved is an easier method.

Immediately on opening the cesspool, a proportion of either of the above solutions is poured into the cesspool. The men who undertake the work soon profit by experience as to the required quantity.

The pump is brought as near to the cesspool as possible; the suction hose is then let down into the cesspool and connected up to the pump, care being taken to screw the connection tight. A length of the delivery hose is then attached to the other end of the pump, and from thence sufficient hose is connected on to reach to the cart or van, when the necessary connection is made to the cast iron bend.

The wire cage over the air valve is filled with cotton waste saturated with crude Sanitas, which is found very effective in suppressing any unpleasant odour which might otherwise arise as the air is expelled through the aperture, the tap being turned full way during the pumping process.

The time actually occupied in filling a 300-gallon van by the two men who are regularly employed is about eight minutes.

DISPOSAL OF SEWAGE.

In districts where the Council have their own horses it would be a matter of arranging with a neighbouring farmer to take the sewage on his land, or if the prospects are that cesspools might be of a long duration in the district, land could be purchased or rented, and the sewage used to irrigate the land for cultivation.

The alternative is to advertise for tenders and accept the best terms for the execution of the work.

In this way all bisecting and complications of accounts are saved, and the actual total cost of working easily obtained.

Following is a specification and form of tender for this work, which will recommend itself for adoption; the paragraphs being varied to suit each separate case.

To the Chairman and Members of the District Council.

GENTLEMEN,—I, the undersigned, do hereby tender and undertake to execute to your satisfaction the work described in the specification hereunder written, at the price mentioned therein, and agree to the terms and conditions following:—

To supply from ..... 1901 to ..... 1902 on every working day, horse and driver, as may from time to time be ordered by the ....., and at the place and hour, or places and hours, as may be required, and to provide a suitable tip for the sewage, at least one hundred yards from any inhabited house or high road, at the price of ..... per day, and ..... per hour for overtime. The horse and driver shall work ten hours per day, exclusively of the time occupied by meals, and in going to and from the work.

The horse and driver to be subject to the approval of the Council, who may from time to time (without stating any reason), summarily dismiss such horse or driver, which in their judgment is unsuited for the work. The contractor to take the risk of all accidents of any kind whatever happening either to horse or driver, and he shall be chargeable for any damage done.

Any question as to any matter or thing arising out of or incident to this contract shall be left to the ...., whose decision shall be final and binding on all parties.

The driver to strictly carry out all directions given to him on behalf of the Council, and cart and dispose of the sewage at the place provided in this contract.

Dated this ..... day of ..... 1901.

Signature .....

Address .....

Profession or calling .....

ITS ADVANTAGES.

(1) No splashing, or offensive smells.

(2) Ensures the work being done more thoroughly and efficiently.

(3) The contents of the cesspool can be taken through the streets without either noses or eyes being offended.

(4) Less labour, and no risks for the men.

(5) No complicated tackle or machinery.

(6) No unpleasant features.

(7) Great saving of cost.

(8) Work can be executed at a substantial profit.

(9) A large cesspool emptied in three hours.

COST OF WORKING.

Much will depend on the situation of the tip for the sewage, the rate of horse hire, and the proximity of the cesspools in the district; but the following is a fair calculation, as, if reference is made to the statistics, the actual cost per cesspool will work out less than the basis given below:—

	£	s.	d.
Horse and driver per day	0	9	0
Two men pumping per day, 3s. 6d. each	0	7	0
28 lb. sulphate of iron	0	1	0
	0	17	0
Add 20 per cent. for depreciation of plant	0	3	5
	1	0	5

Minimum number of cesspools emptied per day, two. Cost per cesspool on above basis, 10s. 2½d.

STATISTICS.

The following is an exact copy of an abstract from

my books of the actual cost of emptying cesspools by the "Bexley" system for the year 1896.

Quarter ending.	No. emptied.	Labour. £ s. d.	Horse hire. £ s. d.	Sulphate of iron. £ s. d.
March 25th	181	27 12 6	48 8 11	3 0 10
June 30th	177	36 16 0	41 8 2	2 9 6
September 29th ...	191	38 12 6	46 2 2	2 15 7
December 25th... ...	168	34 14 0	44 1 6	2 9 3

Actual cost, 9s. 1¾d. per cesspool.
Maximum emptied per day, 4; minimum 2.

SCALE OF CHARGES.

Where cesspools existed in my district, the Council have emptied them free of charge to the owner or occupier, the expense being borne by a sanitary rate, but in a less populous and scattered district this would not be equity, but the following or similar scale of charges could be adopted.

Cesspools are frequently emptied outside my district on this scale, and owners readily pay the charges which, as will be evident from my papers, mean a source of profit to the Council, the amount thus realised in one year being £58 7s. 3d., and this amount was limited owing to the carts not being at liberty, many orders from outside the district being declined on this account.

Mr. E. R. Boulter (late Surveyor to the Bexley Urban Council) has reported that after one year's working, and after allowing 20 per cent. for depreciation, there was a net profit of £150.

	each. £ s. d
Cesspool containing not more than 1000 gallons ..	1 0 0
" " " " 1200 " ..	1 2 6
" " " " 1500 " ..	1 7 6
" " " " 2000 " ..	1 10 0
" " " " 2250 " ..	1 12 6
" " " " 2500 " ..	1 15 0
" " " " 3000 " ..	2 0 0
" " " " 3500 " ..	2 5 0

The number of gallons in any cesspool is easily ascertained by the number of loads removed, the contents of the van being known, or readily ascertained by its cubical contents. Where two cesspools are within easy distance of each other, and the tip for the disposal of the sewage within half a mile radius, the two could easily be emptied in a day. I do not wish that these figures which are put forward should form a hard-and-fast basis, but as the cost of the work has been carefully abstracted from accurately kept accounts, and the cost of maintenance properly arrived at from a full data of working over an extended period of time, some amount of reliance can be placed on the figures and particulars I have given in this paper.

Reference on drawings.—A, cesspool pump; B, rubber armoured suction hose; C, 2¾in. leather delivery hose; D, iron bend for connection of delivery hose; E, air valve; F, manhole or flap; G, discharge valve; H, hose for distribution of sewage.

At a meeting of the Election Committee, held on the 13th inst., the following gentlemen were elected as Associates:—F. Bovey, Holloway; J. Buckeldee, Hillingdon; J. Whittaker, Pleasington.

At the examination in Sanitary Engineering, held on the 22nd and 23rd inst., the following passed, qualifying for Associateship:—W. J. Lane, Croydon; R. J. McKenn, Manchester.

The following meetings will be held on Wednesday, April 10th, 1901:—Examination and Literary Committee at 3 p.m.; General Purposes and Finance Committee at 4 p.m.; Election Committee at 5.15 p.m.; Members' Sessional Meeting at 7 p.m.

THE Norwich Town Council has decided to adopt Part 3 of the Housing of the Working Classes Act, 1890.

THE AIR WE BREATHE.

LECTURING at Brighouse recently, Miss Alice Ravenhill said that it was usual to complain about the keen rushing winds which blew around the Yorkshire hills, and to say that the weather would be much nicer if the wind would go down, yet a strong rushing wind was one of the best purifiers of the air in the world, and but for them the air would become so filthy that it would be impossible to see the light of day through the murky atmosphere. Seventeen times per minute from birth to death air was carried into and ejected from the lungs of every living person. 2600 gallons of air were thus used by each person daily. An ordinary pail held two gallons, therefore 1300 pailfuls of air were used, and it was essential if health was to be maintained that attention should be paid to the quality of this air. If she had to scrub the floor of that school-room, and then offer anyone a drink of the water used, they would say she was demented, and refuse to drink it, yet every day some of them drew air into their lungs which was infinitely more filthy than that water would be, and thought very little about it. Consequently, it was not surprising that there should be so much disease in large unhealthy towns. Rickets in children was largely the result of bad air; pale faces were traceable to the continued breathing of bad air. It was an awful, but nevertheless true fact, that every year 60,000 persons died of consumption in this country, and although they might say that consumption was traceable to the eating of impure food, yet if everyone would insist upon breathing pure air, their bodies would be in a condition to resist the attacks of disease germs.

BAD AIR IN FOOD.

Many people kept wholesome food in very unwholesome places. Foods absorbed air, and therefore if they consumed food which had been stored in a stuffy cupboard, they also consumed a quantity of bad air. If they dropped a lump of sugar into a tumbler of water and waited, they would see bubbles arising to the surface proving that air existed previously in the sugar, which was escaping from the water. Therefore, their nooks, corners, and cupboards required ventilation and cleanliness if their food was to remain good and wholesome. Air held other matters in suspense. Most of them when returning from a visit to the seaside brought back with them a piece of seaweed to use as a weather glass. If the weed was crisp, they forecasted fine weather; if soft and limp, they looked out for rain. The condition of the weed was determined by the amount of moisture held in suspense by the atmosphere, the salt in it being very susceptible to moisture. In a crowded room they would often see water trickling down the walls, although the place might seem very hot, and, similarly if several people were travelling together in a closed railway compartment they might observe how soon the windows became damp and cloudy, and water trickled down. The water was moisture turned from their bodies into the air with every expiration of breath, and the moisture was very dirty and filthy.

EFFECT OF FIRE UPON AIR.

The natural heat of the body was 98 degrees Fahrenheit, and it was possible to get the thermometer to register somewhere about that figure by breathing upon it. Burning spoiled air from a breathing point of view, as it consumed so much oxygen. A fire badly laid would soon smoulder and die out for want of sufficient air. If they confined a taper in an air-tight space it would quickly go out. As soon as the oxygen was consumed the air was no use for human consumption, as all the life-giving oxygen had been extracted, and its place taken by carbonic acid gas. This gas was not in itself bad, but was usually accompanied by two very objectionable companions, organic impurity and sulphuric acid gas, and there-

fore should be avoided. It replaced oxygen, and if the breathing atmosphere was without the proper proportion of oxygen, the body became bloodless, and the hold on life was insecure. Some people kept clean houses and dirty backyards. Decaying vegetable matter and dust were detrimental to health. Dust was made up of all sorts of things—particles of insects, scraps of skin, bits of deceased matter, &c. There was more of this dust in towns than in country places, and that explained why country people were so much more healthy. Nature had provided each one a danger signal, and their noses would tell them when rooms were stuffy and close. Some people kept the best parlour locked up six out of the seven days of the week, and then wondered why it was close and stuffy. The air outside in the street was often a vast deal purer than in the inside of their houses. If they got an ordinary bottle, filled it with water, carried it into the room they wished to test, emptied the water out, they would fill the bottle with the air of the room. Now if they put a table-spoonful of lime-water in the bottle, shook it up, allowed it to stand for half an hour, they could then tell whether the air was pure or not. If it was impure the lime-water would turn a milky colour, and they should make arrangements for purifying the air of their rooms.

SUNSHINE THE BEST PURIFIER.

When selecting a house, they should get one as sunny as possible, as there was no better purifier in the world than sunshine. When the sun shone, let them throw open their doors and windows, and welcome him with open arms. She knew it was customary to draw the blinds to prevent the sun from taking the colour out of the carpets and curtains, but that was a mistake. The sun was one of the finest tonics in the world, and faded carpets were not so important as faded faces. Carpets could be re-placed, but the maintenance of health was surely a more important matter. It was surprising to find how much impurity there was in the atmosphere. In Leeds alone they daily sent up no fewer than 20 tons of soot, and of that three or four settled gently down upon the streets. Town fogs were formed by the moisture in the atmosphere congealing on to the impurities and preventing proper evaporation. When there was a wind there was no fog.

THE VALUE OF PLANTS.

Plants and trees were the regenerators of the air. They consumed carbonic acid gas, which, with its bad companions, was bad for human beings, and in return they breathed out oxygen, which was good for human beings. Ferns and plants were good things to have in rooms. Window boxes were not only a pleasure to the eye, but also assisted considerably in purifying the atmosphere, and the best thing she could recommend for the maintenance of health was the institution of a system of window ventilation, combined with window boxes on the sill, in which mignonette and other sweet-smelling plants might be planted. She also recommended them to keep plants in the bedrooms during the day, as they consumed carbonic acid gas, and in return gave forth the life-giving oxygen. She thought that it was an advantage to frequently sweep both living and bedrooms with air. She was not a believer in draughts, and did not consider it a good thing for anyone to sit in a draught. There were ways and means of ventilating rooms in such a way as to avoid draughts. If work-rooms and houses were properly ventilated, the workers and children would have better appetites for their food, and although they might consume more food, they would make better and healthier men and women. She knew a case which she would like to relate to them. An Inspector of Workshops on one occasion drew the attention of a dressmaker to the inadequate arrangements for ventilating her work-rooms. Eventually she fell in with these views, and ventilated the workshop. A fortnight later her forewoman came to her and remarked that she had been requested by the dressmaker to ask for an increase of wages, and when asked the reason, the person replied that she could eat considerably more and therefore should have better wages. The dressmaker was a wise woman, and knew that during the fortnight she had had fewer complaints from the customers, the work being turned out better, more of it had been done, so she unhesitatingly fell in with the suggestion of the forewoman, and both parties thereby benefited by the change.

TO SWEEP AIR OUT OF THE HOUSE.

The lecturer specially advised a very agreeable precaution to ensure the air of a dwelling-house being sweet, and that was the first thing in the morning and towards night, twice each day, to throw the windows open as far as possible, and open all doors for the space of two to five minutes. They would then have a free passage of air, and the rooms would soon be filled with purer air. Some present might say that at their house this was impossible, as they had a baby or an old person living with them. To prevent them from catching cold a screen arrangement could be made, with an ordinary clothes horse, covered with a shawl, and through this no draught could penetrate. It was customary to close up all apertures in bedrooms in which persons were lying ill, but thiswas a very serious mistake. The first necessity was to obtain purer air, thus enabling the patient to gain sufficient strengh from the oxygenised atmosphere to throw off ill effects of germs of disease. Draughts were more likely to be felt in ill-ventilated rooms than where proper provision was made for ventilation. They could all work that matter out themselves; if they went into a room in which was burning a good fire, shut all the doors, apply a light to any of the cracks or the keyhole of the door, they would find a draught of air sufficient to blow out a candle. If they threw open a door or window the draught would immediately cease.

VENTILATING THE LIVING-ROOM.

It was essential to proper ventilation that the fresh air should enter the upper portion of the room where the heat gathered, as by this means it became warm before descending to the level of the persons standing or sitting in the room, thus making no perceptible draught. Colds, or what we generally call colds, were most often caused through the person shutting himself up in a closed room, and closing all ventilating apertures. She advised people in every case to sleep with some method of ventilation in the bedroom. Personally, wherever she went she always took with her or had made a board 6in. in depth, and the exact width of the window sash. This board she inserted edgeways between the bottom sash, and thus her bedroom was ventilated by the current of air which gained entrance in the narrow slit provided at the top and bottom of the sash. If there was a strong wind, and the possibility of a draught, it was her custom to place a strip of cotton wool along the narrow opening provided, and this succeeded in converting the wind into small streams of air, which were imperceptible. Another means of ventilating their windows was to drill little holes through the sashes. If they were unable to do that, some other course should be adopted. She wished that it was illegal to build a bedroom without a fire-place. In London this progress had been made, but the movement was much slower in the North, and she supposed that a few years would pass before the Authorities recognised the importance of ventilation. London houses were now being ventilated through grates placed in the outer walls provided with hoppers on the inner side. These grates should not be less than 12in. by 6in. Some builders, she was sorry to say, were now putting in those so-called ventilators not larger than 2in. by 2½in. This was decidedly wrong, and was calculated to lull the occupants into a false sense of security, thus doing

considerbly more harm than good. Some remarks on the disadvantges of large furniture in dwelling-rooms brought the lecture to a close.

THE PLUMBERS' COMPANY AND THE REGISTRATION OF PLUMBERS.

At the annual meeting of the Institution of Heating and Ventilating Engineers, held on February 26th, Mr. M. Greenball read a paper on "The Registration of Plumbers." The paper resolved itself into a trenchant criticism of the Plumbers' Company, but how far the facts were correct may be judged from the following letter addressed to the *City Press*, wherein an abstract of Mr. Greenball's paper appeared :—

Dear Sir,—Our attention has been called to a report in the *City Press* of the 2nd inst. in which statements are attributed to you concerning the registration of plumbers and the Plumbers' Company which are contrary to the fact. For example, it is said you stated that since 1884 the Plumbers' Company has spent probably £25,000 on four Parliamentary Bills. This is untrue. The Company and others have spent considerably more than that sum in establishing a system of instruction and examination for plumbers now carried on in London and the chief centres of the kingdom for the purpose of the national registration of plumbers. Again, the statement attributed to you "that the Plumbers' Company were to be the sole administrators of the plumbing industry, power being reserved to them to alter the various clauses at their discretion when the Bill has become law," is also untrue, as may be seen on reference to the Bills. For example, the Bill of 1897 (amended by the Standing Committee on Trade) gives the Plumbers' Company the right to nominate two members out of 47 upon a general council proposed to be created by the Bill under regulations framed by the Local Government Board, and composed of: (1) Master plumbers, builders, ironmongers, sanitary engineers, and other persons carrying on any trade or business employing plumbers; (2) operative plumbers; and (3) members of public Authorities, Medical Officers of Health, or Inspectors. Under the Bill of 1898 the Plumbers' Company would have the nomination of two master plumbers and two operative plumbers out of a total number of 46. Under the Bill the functions of the Plumbers' Company are limited to keeping the register under the control and in accordance with the direction of the Council. Further, the statement that the Plumbers' Company has "flatly refused" an interview with the City and Guilds of London Institute on the subject of the Bills is also contrary to the fact. No such interview has ever been suggested by the Institute. On the contrary, they have so far refused to meet the representatives of the Company to discuss the matter. In view of these and other statements which are contrary to the fact, we must assume that they have been made by inadvertence, or that you have been wrongly reported. It is, of course, not in our province to discuss your opinions on the subject of the registration of plumbers, but it may be remarked that the object of the registration system is, while duly recognising the claim of persons who are at present carrying on the business of plumbers to be registered without examination, to provide adequate training and examination for the coming generation of plumbers, that they may possess—in the language of the Bill—competent knowledge of and skill in the art of plumbing, and such knowledge "of sanitary appliances and their proper construction and adjustment as may enable plumbers to prevent contamination of water and air in dwelling-houses and other buildings by emanations from drains and sewers." As to the question of inspection, the reply appears to us to be well given from the point of view of the public Authorities by Dr. Alfred Hill, the Medical Officer to the city of Birmingham. He tersely summarised the relations which should subsist between the public Authorities and the plumbers by saying, "It is of no use to have good sanitary arrangements and Sanitary Inspectors unless the plumbing work is well done. The Health Committee want really to make the plumbers their technical assistants." It should be remarked that, so far from its being even suggested by the Plumbers' Company that the registration should be left in their hands, the whole history of the registration movement and the Bills promoted in Parliament go to show that the registration system has been carried out in the past by the co-operation of the plumbers, architects, and public Sanitary Authorities and officials, and it is this system which it is now proposed should be consolidated under statutory powers, and the Government are moved by the Health and Water Authorities of the kingdom, as well as by a memorial of about one-third of the members of Parliament to introduce a measure for this purpose in the public interest. In view of the public interest involved, we purpose forwarding a copy of this letter to the editor of the *City Press* with a request for its publication; but before doing so we think it right to call your attention to the mis-statements of fact which are attributed to you, that you may have an opportunity of making any observations you may desire to make before our letter is sent for publication.—Yours, &c.,

Hunter and Haynes,
Solicitors to the promoters of the Bill.

REVIEWS.

The Practical Guide to the Public Health Acts: A Vade Mecum for Officers of Health and Inspectors of Nuisances. By T. Whiteside Hime, B.A., M.D. Second much enlarged edition. London: Bailliere, Tindall, and Cox. Price 15s.

This volume will, we are confident, be warmly welcomed by sanitary officers, that is, Medical Officers of Health and Sanitary Inspectors, as well as Surveyors. There was prior to its publication no volume containing the whole of the Public Health Acts suitable for such officers, and with annotations, available, such as this contains. The statutes could only be found scattered in a number of publications, or separately, in the Queen's printers' edition. The present volume, however, meets the want, for it contains the chief sanitary laws of England, with annotations, and a *précis* of other Acts of importance to Sanitary Authorities, also all important Orders of the Local Government Board, with memoranda on various subjects of especial interest to Medical Officers of Health and Inspectors of Nuisances; with illustrations, diagrams, and tables, and a selected list of important decided cases on sanitary law.

Dr. Hime was formerly, we believe, a Medical Officer of Health, hence he is able to bring his practical knowledge of the working and difficulties of the Acts to bear upon the elucidation of many of their subtleties. His annotations are copious, and marked by a freshness which enhances the value of the book. The cross references are very copiously and carefully done. Sometimes, however, the author permits his own opinions to unduly colour his annotations, as, for instance, his too candid opinion on page 167 on "Medical Officers of Health paying unauthorised official visits to the private patients of other medical men," and on page 171, referring to Sec. 4 of the Infectious Disease (Prevention) Act, 1890, he asserts, "This Section has

been drawn so as to render it as difficult as possible to effect the object in view"! That Dr. Hime is an enthusiast in the interests of public health cannot be denied for a moment, but it is always desirable to remember that private citizens and owners are entitled to justice and reasonable treatment even from Local Authorities.

Referring to the Vaccination Act, 1898, on page 217, the author injudiciously writes that this Act "will probably be the last, as it will put an end to all vaccination," a prophecy which events have shown is entirely wrong. In his "Hints as to Reports of Medical Officers of Health" he has some scathing and cynical observations as to the Local Government Board and Sanitary Authorities in particular. The Model Bye-laws of the Local Government Board as to new buildings, slaughter-houses, and the various offensive trades, are reproduced in the volume.

"Hints" on the compilation of statistics, refuse destructors, meat, and other kinds of food, water supply, &c., and on various other matters of great value to officers of health, are given. The appendix contains reports of a number of cases on sanitary law decided in the Superior Courts, but these reports are shorn of their value for reference by the neglect to make an index of the subjects, as the reader must wade through every case to ascertain whether it has a bearing on the subject in which he is interested.

The profusion of Latin quotations throughout the book is neither warranted nor to be encouraged. The author may be a good Latin scholar, but such a volume as this is not suitable to proclaim it.

These are, however, minor blemishes in a book which possesses great interest to sanitary officers. Its compilation has been a task in which great care and much thought have been exercised, for it contains almost every Act and Order bearing directly or indirectly on sanitary matters. In our opinion, no Medical Officer of Health can afford to be without a copy in his library, and in like manner it should be possessed by other health officers.

LAW CASES.

Chairman of a Sanitary Committee heavily Fined for Assault.

John Anderson, chairman of the Sanitary Committee of the Walthamstow District Council, of Somers-road, Walthamstow, was summoned at Stratford for assaulting John R. Friend, a member of the same Committee, at Walthamstow.

Defendant pleaded guilty.

Mr. Grubbe, for the complainant, said both men were members of the Walthamstow District Council, the defendant being chairman of the Sanitary Committee. On March 19th, at a meeting of the Committee, Mr. Friend proposed that certain work be at once proceeded with, and this was seconded by a Mr. Geary. Defendant became very angry, and interrupted the proceedings, saying, "Sit down, I will not put the motion." Mr. Friend asked "Why?" The defendant retorted, "Shut up, sit down, I won't listen to you. What do I care for you?" Resenting this, Mr. Friend exclaimed, "I don't care much for such a 'thing' as you." Defendant thereupon threw the head of the chairman's mallet at Mr. Friend, but fortunately missed him. He then sprang from his seat, and saying, "I'll knock your head off," ran down the room towards Mr. Friend. Two Councillors tried to restrain him, but he broke away from them. As he approached, Mr. Friend said, "Don't be foolish. I won't put my hands up to you. If you strike me I'll take you to Stratford Police-court." Defendant, however, hit him a violent blow in the face—an exceedingly cowardly blow, for the defendant was a younger and more powerful man, and Mr. Friend was in a sitting position. The blow drew blood. Dr. Clark attended to Mr. Friend, and while this was being done the defendant said that complainant had made a remark that was insulting to his mother.

Defendant: Quite right.

Mr. Grubbe suggested that this remark was an afterthought. Mr. Friend had two front teeth loosened, and as soon as the inflammation had subsided they would have to be drawn. Two other teeth were also slightly loosened. Defendant had made a public apology to the Council, saying his temper had overcome him, but Mr. Friend, under the circumstances, found it impossible to accept that apology. It was not the first or the second time that the defendant had threatened complainant, and not the first time he had attempted violence.

The defendant denied that he used bad language. When Mr. Friend repeatedly refused to withdraw the sentence in which the word "thing" occurred, he (defendant) lost his temper, and took the word "thing" as a gross insult to his parentage. The utmost malice was brought to bear against him, and those prosecuting him that day had done their best to absolutely ruin him in body and life.

The Chairman (Mr. B. Tabrum): That has nothing to do with this case.

Defendant added that when he discovered that no reflection on his parentage was intended he apologised.

The Chairman observed that defendant had acted as a Justice of the Peace for twelve months, and there was, therefore, less excuse for him. A fine of £5, including costs, was imposed.

What is Trade Refuse?

At Dundee Police-court, before Bailie Melville, James Bruce (13), message boy, Forest Park-road, pleaded not guilty to having in contravention of the eighth section of the rules, orders, and regulations enacted by the Magistrates and Town Council, deposited a quantity of waste paper, sawdust, pasteboard, pieces of wood, and other trade rubbish in an ashpit in Constitution-road, on Friday, 20th March. The case was defended by Mr. J. A. Kyd.

From the evidence for the prosecution it appeared that the boy, who was in the employment of the Dundee Eastern Co-operative Society, emptied two small barrels filled with sawdust, waste paper, broken cardboard boxes, spoiled oranges and chips of wood into the ashpit in rear of the Society's premises in Constitution-road. The stuff was held by the prosecutor as coming under the definition of "trade rubbish" specified in the bye-law in question.

Mr. Kyd said that he appeared on behalf of the Co-operative Society, who were acting in concert with a great many other shopkeepers, who found it a great inconvenience to get rid of the accumulations of refuse in connection with their business. It would be desirable to have a definition of what was "trade rubbish," as he did not think that three or four pounds of shop sweepings could be so defined.

Bailie Melville said he was not going to define what was actually refuse, or what quantity of waste paper might be deposited in an ashpit. He thought, however, that boxes, pieces of wood, and the sawdust came within the clause of the 8th Bye-law. There had been considerable difficulty as to what "trade refuse" actually was. When the question was before the Sanitary Committee it was well threshed out, and it was decided that all accumulations of warehouses and shops should be such. As this case had been brought up as a test case, and Mr. Dewar was not pressing for a penalty, but meant it to act as a warning to others, he therefore dismissed the accused.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

APRIL 4, 1901.

PUBLIC HEALTH IN PARLIAMENT.

THE proceedings in Parliament last week were marked by three measures bearing more or less directly upon the public health. One of these was a Government measure—a Bill to amend the Factories and Workshops Acts, introduced by the Home Secretary; the other two, the London Water Purchase Bill, and the "Pure Beer" Bill, were brought forward by private members for second reading. Of the new Factories Bill little can be said until the Bill itself has been circulated and is in our hands; but Mr. Ritchie said enough to indicate that some of the most objectionable features of the Bill of last year had been eliminated. One of its most important provisions will, we gather, be the transference of the responsibility with regard to the regulations for dangerous trades to the Secretary of State himself, subject, of course, to parliamentary supervision and control, instead of leaving them to be dealt with by arbitration. Another feature is that laundries are now to be definitely brought within the scope of the Factories Acts, and the exemption in last year's Bill in favour of laundries worked as charitable institutions, which Mr. Ritchie himself now admits to have been indefensible, is to be withdrawn. The provisions relating to bakehouses will be strengthened, extended powers given to Local Authorities with regard to sanitation, and certain other additional amendments given effect to, but in the main the Bill will proceed on the lines of last year's Bill. Concurrently with this amending Bill Mr. Ritchie introduced the long-looked-for Consolidating Bill, with the announcement that the two Bills would be pressed forward through Committee *pari passu*, returning to the House as one measure, which he hoped would pass during the present session. When that result is achieved, we shall at last have order in place of chaos in our Factory Act system.

The second reading of the London Water Purchase Bill was rejected by a majority of 77, the figures being 253 against 176. The Bill was the same as was introduced last year, which met with a similar fate—to empower the London County Council to acquire the undertakings of the London water companies. With regard to its essential principle, the necessity of purchase, there was little difference of opinion. Mr. Long frankly admitted it; and, further, that purchase could not be delayed. The crux of the whole question is as to the purchasing Authority. The promoters of the measure held that the County Council had obtained at the last election a clear mandate on this question from the municipal ratepayers, and the Council was practically unanimous on the subject. But Sir F. Dixon-Hartland and others doubted if the victory of the Progressives could be construed into a mandate that the County Council should buy out the water companies; for other factors, such as dissatisfaction with the new regulations proposed by the companies, were at work at the time. The proposals in the Bill are directly in the teeth of the recommendations of the Royal Commission that the London County Council should *not* be the purchasing Authority, which should be a permanent and not a fluctuating body, and should adequately represent those districts of supply outside the London County Council area. This outside area represents a population of about a million and a-half, with a large number of Urban and Rural District Councils, and they are entitled to be represented on the Water Board. Mr. Long, on behalf of the Government, stated that they were alive to the necessities of the situation, and he was preparing a measure, which he hoped to

introduce next session, based on the recommendations of the Royal Commission, creating a statutory Authority representative of the whole area concerned, giving proper representation to London as well as the outside districts, with a scheme of purchase just to sellers and buyers alike. Much, therefore, as we should wish to see this pressing question settled this year, we must be content to wait one year more, in the hope that the settlement of the London water question will then be satisfactory and final.

We have included the "Pure Beer" Bill among the measures affecting the public health, for such it was claimed to be by its advocates, but we are doubtful of the justice of the claim. It seems to be really a measure brought forward in the agricultural interest, in order to stimulate the manufacture of beer from malt and hops. It does not, as its predecessors have done in the past, propose to prohibit the manufacture and sale of beer made with substitutes, but seeks to divide beer into two kinds —"malt beer," and "part malt beer," to enable the consumer to know what he drinks. The recent epidemic of arsenical poisoning was, of course, founded on in support of the Bill, though unwarrantably, as the whole questions relating to it are at present *sub judice*. In any case, whatever precautions the Commission of Inquiry may recommend to safeguard the purity and wholesomeness of beer, this Bill will not afford the necessary protection. It would give us no guarantee of purity. Sir Michael Foster, the one scientific expert who took part in the debate, condemned the measure, which he held to be retrograde, and as it was also opposed by Ministers and ex-Ministers on both sides of the House, we hardly think it probable that the largeness of the majority with which the second reading was carried should ensure eventual success.

An Evil Spirit at the Cape.

A CUTTING has been sent to us from the *Cape Register*, which shows something of the spirit existing between some of the whites in that country and the Kaffirs. We boast at home that everyone under the Empire flag enjoys perfect freedom, and that the colour of a man's skin makes no difference to his liberty and equality. But the following extract gives another side to the story: "Another evil," says the writer, "demanding immediate remedy is the travelling of natives in the electric tramcars. They should be bundled out, neck-and-crop, and compelled to confine themselves to open cars placed at their disposal by the company. We have no hesitation in saying that the presence of filthy, evil-smelling Kaffirs in the cars is, at a time like this, a source of danger to the white population, and should be prohibited, if necessary, by the Government. The company, doubtless for financial reasons, refuse to take any steps in the matter. At all events, they have refused hitherto. That being so, some pressure should be brought to bear. We have always contended that in any circumstances the presence of the Kaffir on the tramcars with whites is highly undesirable; in existing circumstances it is positively criminal." If this is to be the spirit of the new rule in South Africa, it bodes no good for the future. The poor Kaffirs may be backward in their ideas of cleanliness and other advantages of civilisation, but it is our mission to lift them out of their darkness, not to revive the worst form and spirit of the old slavery days. People who deal with "natives" after the spirit shown in this deliverance are often little better in their habits than those they denounce. They pollute the atmosphere — both moral and physical—and are quite as unfitted for refined society as the poor black just emerged from the dark forest.

Cremation in Canada.

A MONTREAL telegram announces that Parliamentary sanction has been given to cremation in Quebec, and as it is claimed that the Legislature of Quebec is the first British Parliament in the world to enact measures authorising cremation, the announcement is of great interest. The enactment does not, however, appear to have been a general one. It arose under special circumstances. Sir William Macdonald recently presented a crematorium to Mount Royal Protestant Cemetery. Under the Act of Incorporation by the Legislature of Quebec, it is stated, the management of the country was compelled to procure the sanction of the Legislature before accepting the gift, and this was accordingly done. The circumstance derives additional interest from the fact that the large proportion of the inhabitants of Quebec are Roman Catholics, whose Church is opposed to cremation. But many of the Roman Catholics supported the measure on the ground that Protestants were entitled to cremation if they wished it. The result was the adoption of the Bill, after a keen fight, by a majority of one, the opposition, we gather, being solely dictated by religious motives.

Sanitary Progress in Australia.

NOTHING is more marked than the great advance taking place in sanitary matters in the newly-established Commonwealth of the Southern seas. The various colonies are exceedingly watchful of each others' doings, more especially since the outbreak of plague last year. Melbourne and Sydney have recently been criticising each others' methods of street scavenging. According to the latest advices, Dr. Gresswell, the chairman of the Melbourne Board of Health, thoroughly endorses the opinion of the Mayor of Sydney that the Melbourne system of clearing away garbage is in such a primitive state as to compare very badly with the Sydney method. Even before the plague broke out, says Dr. Gresswell, the disposal of garbage was carried out much more effectively in Sydney than ever it has been in Melbourne. The complaints regarding the Moore Park tip were justified, but that rubbish ground was a sanitary paradise compared with the promiscuously selected depositories in Melbourne for the raking of streets and back yards. "In Melbourne," says

the Doctor, "one never knows where next his nostrils will be assaulted by the odour of collected city filth. I used to take a constitutional across Prince's-bridge and along the Domain-road, but as the vicinity has been made a dumping-ground for a mass of decadent matter I have given up my morning stroll." The method of picking up the street garbage in Melbourne is, according to Dr. Gresswell, slovenly in the extreme, and he agrees with the Mayor of Sydney that the wooden Corporation carts are old, dirty, and defective. He pronounces the entire scavenging system virtually useless. The people of Sydney, he adds, can in sanitary matters give lessons to the people of Melbourne. The Mayor of Sydney's criticism of Melbourne's method of dealing with street garbage is regarded by the Mayor of Melbourne as rather sweeping. Melbourne, he says, is doing what Sydney is proposing to do, and for some time past most of the offensive portion of the street garbage has been treated at the Corporation destructors. A sum of £20,000 has been ear-marked for the purpose of an extensive destructor plant, and the Council will then be in a position to similarly treat the whole of the refuse. This is the kind of warfare we delight to see—a desire to excel in all matters relating to public health.

The Plague at the Cape.

The latest telegrams from the Cape state that the plague is assuming a grave aspect. The proportion of cases among Europeans is increasing, and several cases have occurred among the troops. The difficulty with the Malay population has not yet been tided over, notwithstanding the support which the Government have received from the priests. There is a strong party of irreconcileables who are being humoured as far as possible, but who, it is feared, may have to be dealt with by force if they continue to hamper the restrictive measures. These Malays, who number many thousands, are, it appears, descendants of people banished by the Dutch from Java and Sumatra, and held as slaves by the Cape Boers until their emancipation by the British Government. They are said to be industrious, law-abiding, and loyal subjects, puritanical Mahommedans in regard to ablutions, prayers, and other observances, although they are no polygamists, and giving their women the freedom of Europeans. They are clean in person and in their houses, and in this respect present a great contrast to the Kaffirs. It is suggested that their present alarm must be due to the fact that many of the Kaffirs, who were expelled to be placed in the Government locations, were tenants of theirs, for the Malays own a great deal of house property in Cape Town, much of it, no doubt, of the poorest class.

Fortunate Swansea.

It is not often that a public body comes out of a dispute with contractors in the satisfactory way to itself that the Swansea County Council has in the disagreement over the Cray Waterworks contract. The points at issue between the Council and Messrs. Patterson related to certain preparatory work and extras in connection with the reservoir. The claim sent in for these amounted to over £88,842, and it is not surprising that the Council resisted so large an addition to the original estimates, and got the matter referred to arbitration. The case came before a specially constituted Board last June, when the counsel for the contractors desired to go to the Divisional Court, and this was done, with very favourable results to the Corporation, for the contractors amended their claim to £66,593 16s. 8d. The matter then went before the Arbitration Board, and counsel for the contractors here decided to further reduce their claim to £29,750. Upon this amount the claim was met on every single point, and great credit is due to the Town Clerk for the way in which he instructed counsel. It was reported at the last meeting of the Council that in the end the award amounted to £3788 17s., out of which the Corporation had already allowed £2886 3s., so that the amount now due to the contractors was only £902 14s. 1d. We have no doubt that the contractors are now very sorry that they put forward such an excessive claim in the first instance. Had they been more reasonable they might have got more. As it is, Swansea should be proud of its Town Clerk, who has shown such skill in combating the claim.

"Heterodoxy" at Haslingden.

As we read a passage in the annual report of Dr. Harrison, of Haslingden, we think we are back in the days of our grandparents, when people believed that every child born into the world must have whooping-cough, measles, and scarlet fever. It may be perfectly true that it is better for an individual to have any or all of these diseases in early years, rather than wait till life is matured. But it is another thing for a Medical Officer of Health to put in his annual report that he "is strongly of opinion that the very best thing to happen to a person is to have scarlet fever while a child, and whilst life is not of the same vital importance as when the person has become a parent. So long as a person has not had the disease he is liable to contract it when exposed to infection, and as a general rule children have it in much milder form than adults and are more likely to recover from it." This is a very innocent-looking opinion, but when circulated broadcast through the Press it may become very harmful. It is calculated to make people careless about their children, and tends to admit the claim that "you are bound to have these diseases." We are quite sure that Dr. Harrison does not mean to imply this. Such an admission would carry with it the belief that all the efforts of a "preventive" character were in vain and so much wasted energy. We are not prepared to admit anything of the kind, and we are too conscious of the after effects of these diseases—to take that ground alone—to cease our efforts in impressing upon people the importance of waging an incessant warfare against zymotic disease of every kind.

The Medical Council.

The provisions of the Medical Council Act of 1858 stipulate that the General Medical Council shall annually inform Parliament what are its receipts and expenditure as well as those of the branch Councils for England, Scotland, and Ireland, and also of the apportionment of the amounts payable to the General Council by branch Councils. A return giving this information for 1900 has just been laid on the table of the House of Commons. The revenue of the General Council was benefited to the extent of £45 10s. during the year by the sale of 201 copies of the *Medical Register*, and £17 10s. 3d. came from the sale of "other publications." Four foreign medical titles realised £8, and seven colonial medical qualifications at £5 each brought in £35. The contributions to the General Council by the branch Councils were as follows:—English Branch Council, £4491 14s. 1d.; Scottish Branch Council, £2718 15s. 10d.; Irish Branch Council, £874 0s. 1d. The total income of the Council for the year was £8543 1s. 1d. Taking the General and branch Councils together, it appears that while the total receipts amounted to £11,956 5s. 3d., the total expenditure for the year was £9910 12s. 2d. The fees and other expenses of the General Council absorbed £3459 10s., while the Council's printing account amounted to £1127 8s. 10d. On December 31st last a sum of £1552 13s. 1d. stood to the credit of the English, Scottish, and Irish Branch Councils. In the course of the year a grant of £500 was made to the Irish Branch Council.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

There is no municipal engineer who can afford to lose any opportunity of enhancing his knowledge of the properties and characteristics of limes, mortars, and cements, and I venture to believe that the little book, "Lime, Mortar, and Cement; their Characteristics and Analyses, with an Account of Artificial Stone and Asphalt," price 5s., by W. J. Dibdin, the well-known analytical chemist and author of "The Purification of Sewage and Water," will be warmly welcomed and appreciated by them, as it contains such a storehouse of original information which cannot be found elsewhere, and which is so essential for their use.

Mr. Dibdin, in his practice as an analytical and consulting chemist, is frequently concerned in the analyses of mortars and cements, and in legal proceedings arising from the use of improper mortar by builders, and his opinions and suggestions are therefore of especial value. Surveyors cannot make chemical analyses, and if they did so they would have no weight in a Court of law against properly-qualified analysts, but they should be able to determine by ordinary physical and simple tests the composition of mortar and the impurities contained in it, which Mr. Dibdin so well advises them how to do in his book.

The weakness of the clause in the Model Bye-laws of the Local Government Board relating to mortar is manifest on a study of this book. The bye-laws of the London County Council, made under Sec. 16 of the Metropolis Management and Building Act, 1878, are more specific, and provide that the mortar used under this Act must be composed of freshly-burnt lime, and clean, sharp sand or grit, without earthy matter, in the proportions of one of lime to three of sand or grit. This may be compared with the Model Bye-laws, which prescribe that walls shall be "properly bonded and solidly put together with good mortar, composed of good lime and clean, sharp sand, or other suitable material."

Now, under this clause, there is no restriction that the lime shall be freshly burnt—a most important omission—which enables old mortar to be worked in; nor as to the character or quality of the lime as regards its causticity.

In some parts of the country there is a tendency on the part of speculative builders to use road sweepings in lieu of sand, and also burnt clay ballast, as complying with the requirement of the clause, which allows "other suitable material" than sand to be used. The clause should prohibit the use of organic and earthy matter—the former of which is found in road sweepings, and the latter in improperly-burnt ballast. The observations of the author on the subject, and the methods for detecting the presence of these unsuitable materials, should be known to all surveyors.

I learn that the Royal Commission on Sewage Disposal, appointed in May, 1898, are still unable to state with any degree of precision when their investigations will be completed, inasmuch as some of the questions submitted to them can only be determined after prolonged scientific investigation and inquiry. The secretary of the Commission—Mr. F. J. Willis—has reported to the Treasury that the Commission had held fifty-two meetings, had taken the evidence of eighty-seven witnesses, and visited twenty-two sewage works, and that a large number of chemical and bacteriological investigations in relation to sewage disposal had been made by experts, and that a systematic examination of the results of land treatment of sewage was being carried out. As a matter of fact, Dr. Houston, the well-known bacteriologist, who has been closely associated with the bacteriological experiments which have been conducted for the London County Council at the Barking and Crossness sewage outfall works, has been engaged for more than a year in an elaborate investigation into the character, from a bacteriological point of view, of effluents from sewage after land treatment.

The results of these experiments should be of very considerable interest. It has been shown that effluents from bacterial processes of sewage treatment contain a very large number of bacteria. Some opponents of the system attempt in consequence to depreciate the system, whilst adherents of it claim that the percentages of such bacteria are beneficent, and that they continue actively to increase the purification of the effluents after they have left the bacteria beds. That these micro-organisms play an important part in nature is common knowledge to every thoughtful man now-a-days. It is significant that fresh air contains a greater number of micro-organisms than sewer air, but it does not follow that as a consequence the latter is the ideal atmosphere in which to live, and by a similar deduction it may be found that the pressure of micro-organisms in bacterial sewage effluents is one of nature's own methods, and their absence would be prejudicial. Such micro-organisms are absent in chemically-treated effluents, which are well known to be unsatisfactory and liable to putrefaction. To what extent they exist in effluents from land treatment has not yet been shown, and it is largely on this account that Dr. Houston has been authorised by the Royal Com-

mission to conduct the experiments on such effluents These experiments are not yet concluded, but the results when published must inevitably be interesting.

It is not generally known that surveyors can conduct levelling operations over a tract of country or over roads and ascertain the distance by means of an ordinary levelling telescope and surveying staff without chaining, and as I have been asked to advise on the subject I would point out that Mr. W. H. Wells, the author of the system known as the "Wells" system, has published a pamphlet on it at the price of 1s. This pamphlet fully and clearly describes the simple system. It is also particularly applicable for ascertaining the breadth of large rivers and other obstacles on or off the survey line to be read without measurement.

I understand that the Septic Tank Syndicate, Limited, have declared a dividend of 2½ per cent. on the results of last year's working. This is not quite so good as was expected. The company have at the present time, I am informed, a considerable amount of important work in hand. Senex.

National Health Society.

OFFICIAL TRANSACTIONS.

Training Lectures.—There will be no lectures held at Berners-street during Easter week. The training class will meet again on Monday, April 15th, at 4 p.m., when Dr. Kenwood will give the eighth lecture of his course on "Public Health." On Tuesday, April 16th, Dr. Squire will resume his lectures on "Human Anatomy and Physiology."

We have received the following satisfactory report of the Society's work in Lincolnshire during the past year. "Miss Morgan has given 100 lectures on 'Nursing, Health, and First Aid,' and the interest has been well maintained. Several new centres were started in the spring, notably Market Rasen and Hatton, and the application for a second course in both places within the year was granted by the County Council. In each of the twenty centres an examination was held with most gratifying results to both secretaries and lecturer. It was thought desirable as a further test that a change of examiner should be requested, with the result that an equally large number passed the required examination and gained certificates. The people work really well themselves, meeting in each other's houses for practising and questions, in addition to the weekly lectures and classes."

A very satisfactory examination on "First Aid" was held at Monmouth, on March 28th. The examiner speaks most highly of the work of the candidates, and particularly mentions that the "*vivâ voce* was excellent." Eleven candidates presented themselves, and all have been successful in passing the required standard, the lowest candidate on the list scoring 62 per cent. marks.

The Finance Committee of the Birmingham, Tame, and Rea District Drainage Board reports that it has obtained from the United Kingdom Temperance and General Provident Institution an offer of loans of £42,200 and £7321 at 3¾ per cent. interest for thirty years and forty-five years respectively, being the periods sanctioned by the Local Government Board. The loans are to be repaid by equal annual instalments of principal and interest. The loan of £42,200 is for the construction of the filter beds at the Saltley Works, and the loan of £7321 is for the purchase of the land at Walmley Ash.

Public Works.

SEWERAGE.

The Barrow Rural District Council has accepted the tender of Messrs. H. H. Barry for work at the Birstall sewage works, at £2955.

The Nottingham County Council has decided to lay a new sewer along Nottingham-road, at a cost of £3000, before the proposed tramway is laid.

The Withington Urban District Council intends applying for a loan of £20,000 for sewerage and drainage works at Whalley Range and Chirlton.

The Local Government Board has written the Hungerford District Council, stating that an inquiry will shortly be held into the Council's application to borrow £5812 for drainage purposes.

A meeting of the Scone Drainage Committee was held in the County Buildings, Perth last week, when Mr. Commin, engineer, Exeter, of the Septic Tank Company, explained the system as proposed, to the satisfaction of the Committee.

The Local Government Board has written the Antrim County Council, stating that it has recommended to the Commissioners of Public Works the loan of £1000 sanctioned for the construction of bacteria beds at the Holywell County Asylum for the purfication of sewage.

The Local Government Board has written the Fylde Rural District Council stating that an inquiry will be held shortly with reference to the application of the Council for sanction to borrow £13,900 for purposes of sewerage and sewage disposal for the townships of Bispham, with Nonbrech and Carleton.

Mr. H. Percy Boulnois, one of the Local Government Board Inspectors, recently held an inquiry at Tunstall, into the Urban District Council's application to borrow £2500 for sewerage works. The amount is required for works to deal with the Pittshill district, which has recently been annexed by Tunstall. When the new sewerage scheme for Tunstall, now in course of being carried out. was contemplated, the plans were prepared with a view to sewering Pittshill in case of it being annexed. There was no opposition to the application, but the Inspector intimated that he did not think the Local Government Board would sanction the loan until certain works included in the Tunstall sewerage scheme were concluded.

An interesting installation for purifying the sewage, slops, and refuse liquids from a country house in North Devon, designed by Mr. A. S. Goodridge, A.R.I.B.A., of Bath, has recently been put into operation, the analytical figures showing remarkable results, the effluent from the polarite beds being reported upon by the City Analyst as follows:—"I hereby certify that having analysed a sample of water received on the 4th day of January, 1901, from Mr. A. S. Goodridge, I find the same to contain the following:—Free ammonia, none; albuminoid ammonia (grains per gallon), ·0028; oxygen required to oxidise decomposing matters, none. This is a pure sample of water, no hesitation need be felt in using it for domestic purposes. It contains very small traces of soluble organic matter." These results were obtained by an oxidising bacterial bed composed of coke, sand, and 8in. of polarite, the crude sewage having been merely passed through strainers and an open innoculation tank. It is all disposed of before any putrefaction takes place. The treatment, it will be seen, is of the simplest kind, the use of polarite enabling the sewage at a trifling expense to be converted into practically "pure water."

The Doncaster Rural District Council has decided to apply to the Local Government Board for sanction to a loan for £11,725 for works of sewerage and sewage disposal for the towns of Conisburgh and Denaby, with a population of 16,000. The scheme comprises main and outfall sewers for the towns, also underground storage tank, with a capacity of 80,000 gallons, engine-house, duplicate engines and pumps, bacterial tanks, and laying out of land from the design of Messrs. D. Balfour and Son, of London and Newcastle.

Colonel Durnford, R.E., held a Local Government Board inquiry at New Mill, near Holmfirth, on Wednesday in last week, into the application of the New Mill District Council for sanction to borrow £12,550 for a scheme of sewerage and sewage disposal. Mr. Sam Shaw, C.E., of Dewsbury (the Council's engineer), and the Chairman and Clerk gave evidence. Mr. Jas. Sykes, solicitor, Huddersfield, opposed on behalf of Mrs. Broadhead, an adjoining owner, on the ground that the outfall works would depreciate the value of her property.

Falmouth Corporation has not yet overcome the difficulty of making a final selection from the many drainage schemes submitted to it in competition, by engineers throughout the country. The General Purposes Committee—who are the Corporation sitting in private—have just been engaged in further discussions on the subject. At the first of these meetings they received additional reports from Messrs. Richardson and Le Maitre, and Messrs. Pollard and Tingle (two of the competing firms), as well as a letter from Mr. Valon, C.E. Then there was an adjourned meeting, which resulted in the formulation of a report for submission to the Corporation last week. That report contained the recommendation that a letter be sent to Mr. Brereton, C.E. (who has been appointed umpire), asking if he can lay before General Carey the schemes marked "Automatic" and "Gravitation No. 2," and ascertain from him the attitude of the Local Government Board towards them, and which they would prefer. This recommendation was finally agreed upon by the members.

Dr. Clibborn, Medical Inspector to the Local Government Board, and Mr. P. C. Cowan, M. Inst. C.E., Chief Engineering Inspector to the Board, held an inquiry in the Memorial Hall, Newcastle, co. Limerick, last week, into a complaint received under the Public Health (Ireland) Act, to the effect that the Kilkeel Rural District Council, the Sanitary Authority, had made default in providing Newcastle with sufficient sewers. Colonel Slacke having been examined, Dr. Magill, Medical Officer of Health for Newcastle, was examined as to the state of the sewerage in the town. He strongly condemned the existing sewers, with very few exceptions, and emphasised the necessity for the Council adopting a sewerage scheme, his preference being for a bacterial system of treatment. Mr. J. Findlay Peddie, C.E., gave evidence as to the particular nuisance complained of by Colonel Slacke, and also corroborated the previous witness's evidence as to the want of proper sewerage in the town. Mr. M'Cartan, in explaining the position of the Council in the matter, said they admitted that sewers might be necessary in certain cases, and they were quite prepared to provide them, but they declined to embark upon any sewerage scheme involving a large expenditure, particularly if the area of charge was to be the whole rural district. Evidence on behalf of the Council was given by Mr. Thos. Graham, Clerk of the union, and Mr. Matthew King, chairman. The latter said the Council were willing to carry out a fair system of sewerage for Newcastle, but they held that it would be unreasonable to ask the whole division to bear the expense of an enormous scheme. They admitted that something should be done to improve the sewerage of the town.

The Castle Ward Rural District Council has approved of the sewerage and sewage disposal scheme for Dinnington colliery prepared by Mr. Harry W. Taylor, A.M.I.C.E., of Newcastle-on-Tyne and Birmingham, and application has been made to the Local Government Board for borrowing powers for £2000. The sewage will gravitate to the outfall and be treated bacterially.

A special meeting of the Rochdale paving, sewering, and scavenging Committee was held recently to consider the proposed extension of the Corporation Sewage Works. There was laid before the Committee a scheme comprising a considerable extension of the present works. We understand that the scheme is on the lines of the bacterial system, and will if carried out necessitate an expenditure of over £30,000. The details of the scheme are under consideration, and nothing has as yet been decided upon.

WATER.

The Ashbourne Rural District Council has engaged Mr. Harry W. Taylor, A.M.I.C.E., of Newcastle-on-Tyne and Birmingham, to prepare a scheme of water supply for Kirk Ireton.

The well which has been in course of construction for the Portishead District Water Company is now nearing completion, and to mark the occasion the whole of the workmen have been entertained to dinner at the Priory Hotel by Mr. John Curtis, the energetic manager of the water company.

At the last monthly meeting of Sleaford Rural District Council, Mr. J. Clare submitted a scheme for supplying Digby with waterworks at a cost of £3207, which was adopted. Owing to the scarcity of water at Scredington, it was resolved to cut off all supplies for stock, and only to allow it to be used for domestic purposes.

Mr. M. K. North, C.E., an Inspector of the Local Government Board, visited Newbiggin last week and examined the existing sources of supply, and also viewed the route of the water mains, &c., proposed for the new water supply for the town, which the Council has adopted, as designed by Messrs D. Balfour and Son, civil engineers, including the source of supply with site of additional storage accommodation.

There were 2,672,448,000 gallons of water in the Edinburgh reservoir last week. The total delivery per day during the fortnight ending March 26th was 16,563,000 as compared with 16,546,000 per day during the fortnight ending March 12th. The rainfall at Glencorse since January 1st has been 6·67in., as compared with 11·55in. last year. The rainfall at Gladhouse for the same period has been 5·86in., as compared with 10·57in. last year.

At the meeting of the Barry Gas and Water Committee last week, Mr. E. W. Waite, the Water Engineer, reported that during February the consumption of water by the town was 16,141,700 gallons, the average per day being 555,050 gallons, or 18¼ gallons per head of the population. This is a slight increase on the corresponding month of the previous year. The rainfall for the month was 0·86, a great decrease on the average for the last thirteen years.

At the last meeting of the Upper District Committee of Renfrewshire, it was remitted to a sub-committee to consider and report regarding a water supply scheme for Giffnock and other districts, the area to be included, the estimated cost of capital works and annual outlay, the annual valuation and probable rate of assessment involved, and also as to the probable cost of obtaining an Act of Parliament of the Provisional Order for the providing of a supply of water from the Black Loch in the parish of Mearns.

A MEETING of the Queenstown Council was held last week to confer with the engineers as to the earliest possible date upon which they hoped to be in a position to furnish the Local Government Board with the plans, specification, and estimate in connection with the completion of the waterworks at Tibbetstown, and for the extension to Haulbowline, for which works the Council has applied for a loan of £10,000.

AT its last meeting the Water Committee of the Liverpool City Council agreed upon a recommendation to the Council that a piece of land in St. Helens-road, Eccleston, near Prescot, with the beerhouse known as the Sun Inn, be purchased from Messrs. Greenall, Whitley, and Co., Limited, St. Helens, for the sum of £1000, the Corporation to pay the vendors' solicitors' costs (including negotiation fee) and surveyors' charges. The land is required in connection with the Committee's works.

THE monthly report on the composition of Loch Katrine water, prepared by Professor E. J. Mills, D.Sc., F.R.S., Glasgow and West of Scotland Technical College, has been issued. The results are returned in parts per 100,000. Total solid impurity, 2·500; organic carbon, 0·223; organic nitrogen, 0·027; nitric nitrogen, 0·001; ammonia, 0·000; total combined nitrogen, 0·028; chlorine, 0·72; hardness, 1·27; temperature 5·8 deg. Cent. (=42·4 deg. Fah.) The water was sampled on March 15th. It was light brown in colour, and contained a little suspended matter.

THE Wellington Board of Guardians has given notice to the Wellington Urban District Council that it claims a supply of water for the workhouse on the basis of rateable value as charged to other consumers instead of paying by meter, as hitherto. The claim of the Guardians is based on a case decided in the Court of the King's Bench, in which it was held that the Liskeard Workhouse was entitled to a water supply as for domestic purposes. It is estimated that on the rateable value principle the Guardians would pay two-thirds of what they have hitherto paid. The Urban Council has decided to take counsel's opinion.

THE Bill of the Derwent Valley Water Board came last week before a Select Committee of the House of Commons, presided over by Colonel Welby. The Bill is to empower the Joint Water Board to construct a new railway and to alter a reservoir in the valley. Mr. Balfour Browne, K.C., opened the case for the Bill. Alderman Gainsford (of Sheffield), chairman of the Joint Water Board, and Mr. Edward Sandiman, Engineer, gave evidence in support of the Bill; and Alderman Roberts, ex-Lord Mayor of Sheffield (who was unable to attend afterwards), was examined against the Bill, and spoke of the strong feeling in that city against any interference with the scenery of the valley. The Committee adjourned.

A LECTURE on the Glasgow water supply was delivered by James B. Wylie, A.M.I.C.E., to the Technical College Scientific Society recently. In introducing his subject the lecturer referred to the time when water was sold on the streets of the city at one halfpenny per stoup, and to the days when Clyde water was used for domestic purposes. Passing on to speak of the aqueducts at present in use for conveying the water from Loch Katrine to the reservoirs, Mr. Wyllie minutely described the method of setting out the tunnels by means of observatories placed at the centre of each straight section. The operations of boring and blasting were also explained, and diagrams exhibited showing the sections of the tunnels at various places and the route of the new aqueduct from Loch Katrine. At the close of the lecture a number of slides illustrating the works in progress and the reservoirs of Mugdock and Craigmaddie were thrown on the screen.

AT a meeting of the Dalton Urban District Council last week, the Parliamentary Committee reported that the requests made to the Barrow Corporation for certain privileges in connection with Barrow's water scheme had been refused. Mr. Hamer said he thought this was due to the fact that the Dalton Council was not in a position to fight the matter. He thought the Barrow Corporation had withheld its reply to Dalton until it was too late for the latter to appear against the Bill. No action was decided upon.

LAST week the Select Committee of the House of Commons, of which Mr. Schwann is chairman, commenced consideration of the Tees Valley Water Board Bill. Mr. Balfour Browne, K.C., for the promoters, this was a Bill to confer further powers on the Tees Valley Water Board in relation to the supply of water. He proceeded to explain the circumstances which had led up to the formation of the Board in 1876 by the Local Authorities of Middlesbrough and Stockton, and subsequently of Thornaby, Middlesbrough being interested to the extent of six-twelfths, Stockton five-twelfths, and Thornaby one-twelfth. When the Grassholme reservoir, now under constuction, was completed, the total supply of the company would be 194,568,000 gallons per week, and by that time the consumption, it was estimated, would be 100,000,000 gallons, so that there would be a margin of 94,568,000 gallons a week. It was to enable them to dispose of this margin to anyone who might want it that the present Bill was promoted. Mr. Wilson, general manager of the Tees Valley Waterworks, gave evidence in favour of the Bill, and was still under examination when the Committee adjourned.

LIGHTING.

A LOCAL Government Board inquiry was held at the Town Hall, Newport (Mon.), last week into the application for sanction to borrow £28,000 for electric lighting and £1800 for widening the roads.

THE London County Council has agreed to lend the Hackney Borough Council £30,000 for an electric light installation, the Hammersmith Borough Council £13,530 for the same purpose, and the Stepney Borough Council £5163 for street lighting.

THE Bombay Corporation has empowered the Commissioner and a Committee, subject to compliance with certain specified conditions, to make arrangements with the Pioneer Electric Light and Power Company of London to work the two concessions of the tramways and the electric lighting.

THE Electricity Committee of the Poplar Borough Council has decided, subject to the approval of the Council, to light the Isle of Dogs with the electric light. It is estimated that 100 arc lamps will be required, at an estimated cost of £3277, while the additional charge per annum in excess of the cost of gas lighting will be £877.

A CURIOUS state of affairs has, we understand, arisen in the City owing to the recent decision in the Court of Appeal regarding the invalidity of certain contracts that were entered into some years ago between the late Commission of Sewers and the City of London Electric Lighting Company. The secretary to the company has addressed a letter to the Corporation pointing out that under the recent decision the contracts for the central and western districts are null and void, the consequence being that those agreements between the company and the Corporation as to the supply of electrical current have ceased to exist. In the circumstances the company ask whether the Corporation wishes the public supply continued, and suggest that a small committee should be appointed by the Corporation to discuss the terms for its continuance.

We understand that, as predicted by the Town Clerk at the meeting of the Gravesend Council last week, a settlement has been arrived at with regard to the objections to the parliamentary Bill of the Gravesend Gas Company. The Bill has been considered by a Parliamentary Committee and approved, subject to amendment which the promoters agreed to in order to compromise with the Gravesend and Northfleet Councils as objectors. The terms of the compromise will be duly reported to the respective Councils.

The annual meeting of the Shirebrook and District Gas Company was held last week at Nottingham. The directors' report stated that the necessary Act of Parliament having been obtained, the company was now proceeding with the business for which it was formed. It also stated that of the £16,000 ordinary stock which is now being issued, over £14,000 had been privately subscribed, and applications were being received daily. The laying of the mains and erection and equipment of the works will be proceeded with immediately. The Board anticipates that it will be in a position to supply gas for next winter's consumption.

The report of the Commercial Gas Company for the half-year ended December 31st, 1900, states the net profit at £39,658, making, with £35 received for interest, £39,693. Deducting therefrom £5699 for interest on debenture stock, there remains standing to the credit of the net revenue account a balance of £33,994 available for dividend. The directors recommend the payments of dividends at the rates of 12 per cent. per annum on the old stock of the company, and of 9 per cent. per annum on the new stock. The amount by which the profits of the company are insufficient to pay the dividends will be taken out of the reserve fund.

Since Peebles Corporation took over the gas company's undertaking, the consumpt of gas has greatly increased, and it has been found that the present works were too small for the requirements of the town. The Town Clerk has been instructed to write to Messrs. J. and F. Anderson, W.S., Edinburgh, for the purpose of ascertaining if they would be willing to feu a piece of ground about a mile to the east of Peebles, on the Innerleithen-road, as a site for the proposed new gasworks. Provost Ballantyne has also been requested to ascertain from an electrical engineer if water-power could be used in the event of electric light being introduced.

The Colwyn Bay Urban District Gas Bill came before a Select Committee of the House of Commons last week. The Bill is promoted by the Urban District Council of Colwyn Bay to enable it to acquire the undertaking of the Colwyn Bay Gas Company. In stating the case for the Bill, Mr. Baggallay said the Bill was promoted by the District Council for the transfer of the Colwyn Bay and District Gas Company's undertaking to the District Council. The Committee, he said, would not be troubled with any question as to whether there should not be a transfer—that had already been dealt with under a Bill. The preamble of the Bill was finally proved.

Mr. Frederick Punchard, of Kirkby Lonsdale, the umpire in the arbitration proceedings between the Ossett Corporation and the Ossett Gas Company, for the compulsory purchase of the works and undertaking of the company, gave his award last week, and it amounts to £97,500. The Corporation also takes over a mortgage of £7000. The share capital of the company amounts to £43,000, of which £15,000 carries 10 per cent. and £28,000 7 per cent. The shareholders will receive a little over 28 years' purchase of the maximum dividends. The company's valuers claimed £117,110, and the Corporation is understood to have offered £87,000.

The Bill promoted in Parliament by the Honley Urban District Council for taking over the Honley Gas Company's undertaking has passed the Committee of Ways and Means as an unopposed measure. At the suggestion of the promoters, the Committee struck out the clause relating to the adjustment of charges for penny-in-the-slot meters. The Bill has been sent for third reading.

We understand that Messrs. Siemens and Co., the well-known electrical construction engineers, have completed the purchase of the land at The Hough, Stafford, which they require for the erection of their extensive new works. The negotiations have been completed with Messrs. Hand and Co., through Messrs. E. W. and W. H. Turnor, agents for the owners, the Rev. C. C. Ellison, Sir T. Salt, Bart., and the Grammar School Trustees. The land already acquired comprises about 51 acres, and extends from the Queensville Bridge to the Crinoline Bridge along the east side of the London and North-Western Railway. It is not proposed to interfere with the Stafford Cricket Club ground. The company are now negotiating with Messrs. Turnor for the purchase of a further 10½ acres of land forming part of the Stych Fields, and extending from the Crinoline Bridge to the Talbot and Ingestre roads, and we understand the company propose to erect on this land about a thousand dwellings for the accommodation of their employés. Building operations will, we believe, be commenced very shortly.

GENERAL.

A measles epidemic has led to the closing for a while of Campsbourne Infants' School, Hornsey.

The Beccles Town Council has adopted plans and estimates for alteration of the Town Hall at a cost of £700.

The London County Council has agreed to lend the Lewisham Borough Council £1000 for asphalte paving works.

The Bromley Rural District Council has decided to contribute a sum of £2900 towards the West Wickham sanitation scheme.

Major Slacke held an inquiry at Bingley Town Hall recently with reference to an application of the District Council to borrow £4250 for various works.

The Court of Common Council has decided to contribute the sum of 100 guineas out of the City's cash towards the purposes of the British Congress on Tuberculosis, of which his Majesty the King was, as Prince of Wales, president, and Sir William Broadbent, Bart., F.R.S., is the chairman of the Council, and that the Chamberlain pay the same to the treasurer of the congress.

At the last monthly meeting of the Goole Urban District Council the Highways and Sewers Committee recommended that the scheme of the Surveyor for paving several of the streets of the town with wood and granite setts, at a cost of £13,742, be adopted, and that the Clerk apply to the Local Government Board for power to borrow £12,092 for the completion of the work. The recommendation was adopted.

Mr. William Keith, County Sanitary Inspector, Clackmannanshire, has issued his report upon the sanitary condition of the county and burgh for 1900. Mr. Keith states that during the year steady progress had been maintained in building and repairing houses for the working classes. A good many houses had been erected in the various villages and fitted up with all modern requirements. All workshops had been kept in order. All places of interment were kept in a satisfactory state. Steady progress was being made in the way of providing a purer milk supply.

The making up of private streets in the urban district of Hindley will involve an outlay of £16,000.

The Bedworth Committee of the Foleshill Rural District Council last week presented a report to the latter body on Dr. Bostock Hill's report to the Warwickshire County Council. The Committee stated that there was now a public supply of water, and the Sanitary Inspector was requested to periodically take samples from existing wells. The scavenging was being improved, but the Nuneaton and Chilvers Coton District Council had complained of the discharge of sewage into the river Anker from Bedworth. The report was adopted by the Council.

We understand that an important movement is on foot at present with regard to insanitary dwellings in Perth. The question has been raised by a number of gentlemen much interested in the matter, and certain steps have already been taken in the scheme. It is alleged there are a large number of insanitary dwellings in Perth, and as the Local Authority has power under the Act to compel landlords to put these houses into a fit sanitary condition, these gentlemen intend to insist on the Local Authority using its power, and should the Local Authority fail to do so the matter in all probability will be laid before a higher authority. The scheme promises to be an extensive one, and a meeting will in all probability be held at an early date for the purpose of electing a Committee thoroughly representative of the working classes. It is proposed to ask the co-operation of all friendly societies and organisations interested in the working classes.

Under the Cleansing of Persons Act, Marylebone Borough Council now provides hot baths and accommodation for the simultaneous disinfection of clothing for persons of both sexes, but during the past year a much smaller number of women than was expected have taken advantage of the provision. The number is, however, gradually increasing. During the past twelve months 3352 men and 28 women underwent the cleansing process, and had their clothes disinfected. A considerable number of these poor people, says the Medical Officer of Health, were in a most offensive condition, swarming with parasites, and generally in a deplorable state—so much so, that they would have infected any public seat or conveyance they made use of. The great majority of the applicants for the cleansing process came from the Salvation Army Home in Burne-street, showing the good influence the authorities at this home exercise on the poor people for whom they provide, in instilling in their minds the necessity of cleanliness.

At last week's meeting of the North Dublin Union the clerk stated that Dr. Edgar Flinn had been asked by the Local Government Board to make a report with regard to matters relating to the public health of Howth. The report, which was called for owing to the prevalence of diphtheria, had been sent on to the Council by the Local Government Board. It contained a number of suggestions made by Dr. Flinn, among which were the provision of a properly devised plan of sewerage and drainage; healthy dwellings for the labouring classes were urgently needed, accompanied by a strict enforcement of the law as to the closing of houses that had been condemned as unfit for human habitation; an improvement in the system of public and domestic cleansing, and the more frequent removal of filth accumulations from the backyards of small cabin dwellings was necessary, and house-to-house inspections should be made at regular intervals, as accumulations of house filth had been allowed to remain unremoved for too long a period; cowsheds, dairies, and slaughter yards required inspection; the provision of a disinfecting chamber might be considered by the Council; an estimate should be obtained of the cost of a sufficient supply of good water; the temporary closing of the schools was also suggested owing to occurrence of dipththeria.

PERSONAL.

Dr. J. A. Rees has been appointed Medical Officer of Health for Aberystwith.

Mr. Winton, gas manager for West Calder, has been appointed Manager of the Moffatt Gas Company.

Mr. A. Hodgkins has been appointed Inspector under the Sale of Food and Drugs Act for Henley.

Dr. Hamilton has resigned his position as resident Medical Officer at Smithston Asylum and Poorhouse.

Mr. George Cunningham, jun., has been appointed superintendent of the sewage filtration fields at Denny.

Mr. A. G. Gray has been appointed Sanitary Inspector for Wallingford, at a salary of £25 per annum.

Mr. J. V. Snowden has been appointed Inspector of Nuisances for Tamworth, at a salary of £120 per annum.

Dr. White has been reappointed Medical Officer of Health, and Mr. E. Edwards Inspector of Nuisances for Corwen.

Mr. J. W. Bradley, Borough Surveyor of Wolverhampton, has been appointed City Engineer to the Council.

Mr. R. M. Prescott, Town Clerk of Nelson, has been appointed Town Clerk for the Borough Council of Fulham.

Mr. G. H. Pegram, A.S.I., has been unanimously reappointed Inspector of Nuisances to the Epping Urban District Council.

The Local Government Board has sanctioned the reappointment of Dr. R. T. Richardson as Medical Officer of Health for Trowbridge.

The Local Government Board has sanctioned the reappointment of Dr. A. K. Gale as Medical Officer of Health for the rural district of Norton.

Mr. N. G. Fish has been reappointed Inspector of Nuisances under the Yeovil Rural District Council, at a salary of £70 per annum. He will also act as Petroleum Inspector.

Mr. James A. Budge has resigned his position as Burgh Surveyor and Sanitary Inspector for Buckie, in consequence of his having accepted the appointment of Deputy Road Surveyor for Birmingham, at a salary of £180 per annum.

We regret to announce the death of Dr. W. H. Turnbull, Medical Officer of Health of South Shields, at the early age of thirty-two years. Dr. Turnbull was a native of Houghton-le-Spring, and took the degrees of M.B. and B.S. at Durham in 1890; B.Hy. in 1891; and D.Hy. at Newcastle in 1895.

Sanction has been given by the Local Government Board to the appointment of Dr. W. A. Bond as Medical Officer of Health of Holborn, and Dr. J. J. Allan as Medical Officer of Health of the city of Westminster. It has also confirmed the appointments of the following Sanitary Inspectors:—Mr. J. Johnson, Poplar; Mr. W. J. Storer and Mr. E. J. Dillon, St. Pancras.

It was stated at the meeting of the London School Board last week that the resolution of the Board to increase the salary of its Medical Officer to £800 on condition that he held no other appointment except his King's College professorship has not met with the approval of Dr. William Smith, the officer in question, and he has written stating that he could not accept the increase on the conditions suggested, as it placed a restriction on himself which was not found to apply to any other official in the Board's service. The General Purposes Committee will consider and report on the communication.

The Hornsey Urban District Council has advanced Mr. Lovegrove's salary to £850, to be further increased next year by £50.

Dr. Telfer Thomas and Mr. J. Williams have been re-elected Medical Officer and Sanitary Inspector respectively for Camborne.

Mr. N. W. Hoskins, F.I.S.E., of New Eltham, S.E., has been appointed Lecturer in Sanitary Science at the City of London College.

The Local Government Board has sanctioned the re-appointment of Mr. Fred. Wadsworth as Sanitary Inspector for Holmfirth.

Mr. S. Turner, Surveyor of Brentwood, Essex, has been appointed Surveyor and Inspector of Nuisances for the urban district of Knaresborough, at a salary of £125 per annum.

The Local Government Board has approved the appointment of Mr. F. Halliday, as Sanitary Inspector for the rural district of Castle Donington, at a salary of £45 per annum.

Three names have been selected by the Sanitary Committee of the City of London, from which the Common Council will select an Analyst on the 25th inst. They are:—Dr. M. W. Blyth, Public Analyst to the boroughs of Eastbourne and Brighton; Dr. S. Rideal, vice-president of the Society of Public Analysts; Dr. F. L. Teed, Public Analyst to the boroughs of Islington and Camberwell.

We are informed that Mr. Peter Fyfe, Chief Sanitary Inspector of Glasgow, has a book in hand dealing with the social problem in the various aspects under which it has presented itself to him during his professional career in Glasgow. Mr. Fyfe promises to continue the literary reputation of the Health Department, of which Sir W. T. Gairdner, K.C.B., laid the foundation, and to which Dr. Russell, while Medical Officer of Health, made many notable contributions.

The Sanitary Committee of the City of London met last week, and made a selection of six names to be submitted to the Common Council from which to appoint a Medical Officer of Health for the City of London. The selected candidates are:—Dr. W. A. Bond, Medical Officer of Health to the Holborn Borough Council; Dr. Collingridge, Medical Officer of Health of the Port of London; Dr. Robt. Sydney Marsden, Medical Officer of Birkenhead; Dr. N. C. Pattin, Medical Officer of Health to the Corporation of Norwich; Dr. J. Priestley, the Medical Officer of Health for Lambeth; Dr. F. J. Waldo, Medical Officer of Health for the Inner and Middle Temples, and late Medical Officer for St. George the Martyr, Southwark. The appointment will be made on the 25th inst.

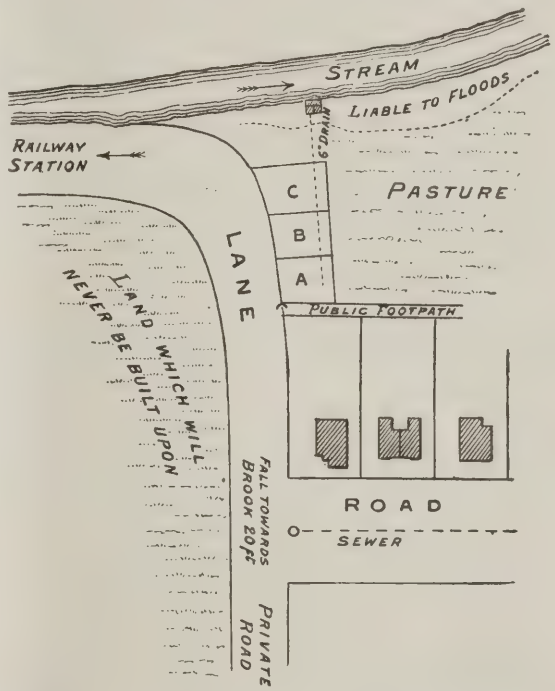
NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2134.—Defective Drainage: Proceedings.—"Inspector" writes:—"On testing the drainage of a semi-detached house with the smoke test, smoke was found to exude from some of the joints of the yard paving. Some of the surface traps are D traps cemented down, and resisted the smoke test, consequently no evidence of a defect was found here. The drain pipes are of good 6in. stoneware. (1) Will you kindly advise which is the best section to proceed under when serving notices? I have asked for instructions to serve notices under Sec. 23 of the Act of 1875, to get iron traps replaced with stoneware gullies when they are gas-tight, and when found to leak, under Sec. 94. Is this right? (2) An assistant Sanitary Inspector tested the drainage of a street of houses. The several owners were informed of such intention and the occupiers raised no objections. All the drains were found to be more or less defective. The assistant reported same to the Council on a written complaint, *i.e.*, one street with the several owners and occupiers named in a schedule. Can notices under Sec. 41 of the Act of 1875 be served in this case by the chief Inspector without having a written order from the Council to enter premises and examine, seeing that a nuisance is known to exist, and the occupiers have no objection?"

Answer.—(1) In cases of defective drainage it is generally advisable to serve statutory notices under Sec. 23 or under Sec. 41 of the Act of 1875, and not under Sec. 94. When notices are served under the last-named section, and the owner makes default in complying with such notice, the Local Authority are not empowered on his default to do the work (as is the case under Secs. 23 and 41), but must summon him to appear before a court of summary jurisdiction, when it is for the authority to prove, to the satisfaction of the magistrates, who will require conclusive proof, that the defective drain is a nuisance. When the drain is so defective that an entirely new drain is to be substituted, notice should be served under Sec. 23, but when the drain requires only alteration or amendment, notice may be served under Sec. 41. (2) Yes; notice may be served upon the owners under Sec. 41 in the absence of a previous authority of the Council in writing to the Inspector to enter the premises. Notice to the owners under Sec. 23 would be equally as effective as under Sec. 41.

2135.—Sewage Disposal for Three Houses: Scheme.—"A. T. B." writes:—"The owner of a pasture field shown on sketch has recently sold to A, B, and C, building plots adjacent to the lane. The nearest sewer is three-hundred yards distant, and it is also at a level of 10ft. higher than the site of the houses. The Local Authority who have recently taken over the lane have no intention of sewering it. The owners of the plots require to build, and appeal to me to put in a sewer for them or to allow them to put in cesspools. The former I cannot do and the latter I discountenance. I suggest that they should come to an agree-



ment with the owner of the pasture to enable them to lay a 6in. main drain from their plots into a septic tank and bacteria beds at the side of the brook. Will you please give your opinion on the subject?"

Answer.—The scheme suggested by our correspondent is to be recommended. Coarse and fine bacteria beds should be constructed, and a tank if necessary. The tank and beds must not, however, be placed as shown, which is within the area liable to floods. The owners, A, B, and C, may, of course, appeal to the Local Government Board to call upon the Local Authority to provide them with a sufficient sewer. These houses are within the drainage area, and the owners will have to pay the rates for the maintenance of sewers for others, and also construct and maintain their own sewers, to which they may fairly object.

2136.—Unsound Meat on Board Vessels: Inspector cannot Seize.—"W. J. H." writes:—"I am an Inspector for a Port Sanitary Authority, and on visiting vessels I sometimes find a quantity of meat stored thereon unfit for human food. As a rule

the masters of the vessels will destroy it on their attention being drawn to it. I should like to know if an Inspector can seize meat unfit for human food on board vessels although the same is not exposed for sale. I may point out that the meat is placed on board for the use of the men, and is sometimes kept on board for five or six months. Can a Port Sanitary Inspector take proceedings against the captain for issuing to his crew meat unfit for food.

Answer.—No. The Port Sanitary Authority, through their officer, are not enabled to seize unsound meat under the provisions of Secs. 116 and 117 of the Act of 1875, relating to unsound meat, when such unsound meat is not exposed or deposited for or in preparation for sale. Neither can they take proceedings against the captain for having such meat in his possession, unless it is intended for sale as human food. It is a condition preliminary to such proceedings that the meat must be for sale or intended for sale for the food of man, and these conditions are absent in the case named by the querist.

2137.—Stable is a Domestic Building under Building Bye-laws.—"Engineer and Surveyor" writes:—"My Council have the Model Bye-laws as to New Streets and Buildings in force in the district. There is no definition as to whether a stable and coach-house comes under the head of a 'building of the warehouse class,' or whether it is a 'domestic building.' Will you kindly give me your views on the subject?"

Answer.—A stable is a "domestic building," and the provisions of the bye-laws as regards the mode of construction of "domestic buildings," open space at rear, &c., may be enforced. We answered a similar query—No. 1862—in our issue of June 26th, to which we advise the querist to refer.

2138.—Nuisance from Defective Spouting.—"Subscriber" writes: "In this district, which is a rural one, I have served notices on a large number of owners with reference to the insanitary condition of their property. A portion of these notices refers to defective gutters and downspouts. In some instances such gutters have never been fixed whilst others have been allowed to get into a bad state. Complaints have been made in many cases concerning damp walls, floors, &c., due to the want of or defective gutters and downspouts, as the water flows off the roofs and down the walls and percolating under the ground floor, causes a considerable amount of dampness. I have been told by one person that I have no power to interfere in cases of this kind. Will you kindly advise (1) Can such cases be dealt with under Sec. 91 of the Public Health Act, 1875, where no gutters and downspouts have been fixed, and also where they have been fixed and allowed to get into a bad state, and can you give me any case or cases which have been decided on these points?"

Answer.—For the purposes of the Public Health Act any premises which are, as defined by Sec. 91, in such a state as to be a nuisance or injurious to health shall be deemed to be a nuisance liable to be dealt with summarily in manner provided by the Act. There is no doubt, in our opinion, that dampness in dwelling-houses caused by the absence of or defective rain-water spouting is a nuisance within the section. In confirmation of this view we may cite the judgment of Wills, J., in Reg. *v.* Parlby, 22 Q.B.D., 520; 60 L.T. (N.S.) 422; 53 J.P. 327, in which he says that the clause of Sec. 91 to which we have referred is confined to cases in which the premises themselves are decayed, dilapidated, dirty, or out of order, as for instance where houses have been inhabited by tenants whose habits and ways of life have rendered them filthy or impregnated them with disease, or where foul matter has been allowed to soak into walls or floors, or where they are so dilapidated as to be a source of danger to life or limb.

2139.—Sanitary Inspector's Duties: Superintending Abatement of Nuisances. — "Sanitary Inspector" writes:—"The Health Committee of this Urban Sanitary Authority have provided a book into which I, as Sanitary Inspector, must enter all nuisances that have been reported to the Committee, and for the abatement of which they have been given orders for a legal notice to be served upon the persons in default. After the particulars have been entered in the book it has thereupon to be inspected by the Surveyor to the Council, and if he requires any orders to carry out the works, to remedy the nuisance, or otherwise learns that such works are in progress, he has to superintend and to see to the due execution of the same, and enter into the said book a record of their progress. And, further, he has to superintend the execution of all works required to remedy nuisances arising from structural defects. Will you please advise as to whether the Committee can lawfully order me to produce my book to any official of the Local Authority except the Medical Officer of Health? Can a Sanitary Authority prevent a Sanitary Inspector from superintending the abatement of nuisances if the work is carried out by a contractor, as per Section 13 of the Local Government Board Regulations of the 23rd March, 1891?"

Answer.—By Clause 15 of the General Order of the Local Government Board of the 23rd March, 1891, as to Regulations in respect to the duties of Inspectors of Nuisances, it is provided that "in matters not specially provided for in this Order, the Inspector shall observe and execute all the lawful orders and directions of the Sanitary Authority and the Orders of the Local Government Board which may be hereafter issued, applicable to his office." We are of opinion that the order of the Urban Sanitary Authority requiring the Inspector to produce his books to the Surveyor—though an unusual one—is not an unlawful order, and that it may be enforced. (2) The Clause referred to by the querist provides "that the Inspector shall, if directed by the Sanitary Authority to do so, superintend and see to the due execution of all works which may be undertaken under their direction for the suppression or removal of nuisances within the district." Inasmuch as the Authority has not, as is optional for them, directed the Inspector to superintend the execution of such works, it is not therefore compulsory on him to do so. The procedure of the Sanitary Authority appears to us to be unusual. The Sanitary Inspector may, if he so chooses, see that the work required to be done is carried out. He might usefully seek the opinion of the Local Government Board as to the interpretation they place upon their orders in the cases named by him, by addressing a letter to the Secretary, Local Government Board, Whitehall, London, S.W.

2140.—Sale of Food and Drugs Act, 1899: Selling Milk from Cans without Inscription thereon.—"T. R." writes:—"What is the course of procedure which I ought to take in reference to the following matters:—(1) A milk seller selling milk from a vehicle which has no name or address thereon. (2) A milk seller selling milk from a vehicle with name and address conspicuously inscribed thereon leaves the vehicle at the head of the street after filling a large hand can from it, and proceeds along the back streets selling milk to customers from the hand can on which no name or address is inscribed save that of the maker of the can. (3) A milk seller delivering milk to his customers daily by means of two hand cans alone, on which no name or address is inscribed other than the makers, as in case (2). Does Sec. 9 of the Food and Drugs Act, 1899, mean that all these milk sellers are liable to a penalty?"

Answer.—Yes. Section 9 of the Act referred to applies to each case, and each of the tradesmen contravenes the provisions of the section, and is liable to the prescribed penalty.

2141.—"Proof Spirit": Meaning of Term.—"E. P.," writes:—"Will you kindly give me the definition of 'Proof Spirit,' and how same is to be obtained?"

Answer.—We answered in our issue of May 19th last, Query 1479, a similar query, to which we beg our correspondent to refer.

2142.—Books for Town Surveyors Recommended.—"A. K." writes:—"Will you kindly advise me as to the best books on preparing specifications and bills of quantities, with prices of same for the following classes of work, viz.:—Town surveyor's duties: roadmaking, sewerage works, sewage works, waterworks, &c.; builder's work: plumber, bricklayer, joiner, mason, slater, painter, &c. Also the miscellaneous matters arising in the sanitary administration of towns generally?"

Answer.—The following books are recommended as being probably the best and most up to date of their kind, viz.:—*Roadmaking*: Aitken's "Roadmaking and Maintenance," price 21s.; Boulnois' "Carriageways and Footways," price 5s. *Sewerage and Sewage Disposal Works*: Moore's "Sanitary Engineering," price 32s. net; Dibdin's "Purification of Sewage and Water," price 21s. net; Thudichum's "Bacterial Treatment of Sewage," 1s. 3d.; Adams' "Local Government Board Requirements for Bacterial Sewage Disposal Works," price 2s. 6d.; *Water Supply*: Burton's "Water Supply of Towns and the Construction of Waterworks," price 25s.; McPherson's "Waterworks Distribution," price 7s. 6d. *Builder's Work*: Macey's "Architectural Specifications," price 21s.; also "Specification for Architect, Surveyor, and Engineer," price 5s.; Hellyer's "Plumber and Sanitary Houses," price 12s.; Siebert and Biggins' "Modern Stone Cutting and Masonry," price 7s. 6d.; Rivington's "Building Construction," in 4 vols., price, vol. i., 10s. 6d.; vol. ii., 10s. 6d.; vol. iii., 21s.; and vol. iv., 15s.; Christy's "Joints Made and Used by Builders," price 3s.; Leaning's "Quantity Surveying," price 15s. Other books recommended for a Town Surveyor are Boulnois' "Municipal and Sanitary Engineer's Handbook," price 15s.; Maxwell's "Removal and Disposal of Town Refuse," price 15s.; Dibdin's "Lime, Mortar, and Cement," price 5s.; Jensen's "Modern Drainage Inspection and Sanitary Surveys," price 2s. 6d.; and Jensen's "House Drainage and Sanitary Fitments," price 5s.; Angell and Morley's "Practical Guide to Sanitary Legislation," price 12s.; Mackenzie and Handford's "Model Bye-laws under the Public Health Acts," price 25s. Any of the books may be obtained from the Sanitary Publishing Company.

LIME, MORTAR, & CEMENT:

THEIR CHARACTERISTICS AND ANALYSES, WITH AN ACCOUNT OF

ARTIFICIAL STONE & ASPHALT

By W. J. DIBDIN, F.I.C., F.C.S., F.S.I., &c. &c.,

Formerly Chemist and Superintending Gas Examiner to the Metropolitan Board of Works and London County Council.

THIS BOOK HAS BEEN COMPILED TO MEET THE REQUIREMENTS OF THOSE SEEKING A RELIABLE GUIDE ON THE SUBJECT OF WHICH IT TREATS.

SYNOPSIS OF CHAPTERS.

Characteristics of Various Limes—Clay—Sand and its Substitutes—Mortar and Cement—The Setting of Mortar and Cement—Rough Technical Tests of Mortar without Chemical Analysis—The Chemical Analysis of Lime, Mortar, Cement, &c.—Typical Analysis of Mortar and Cement—Mechanical Tests of Cement—The Adulteration of Portland Cement—The Strength of Brickwork—Concrete—Artificial Stone—Asphalt.

PRESS OPINIONS.

"A very useful little treatise. . . . It deals with the character and chemical composition of the various materials used in making mortars and cements, and the methods and results of their chemical analysis. . . . We recommend this book not only as an excellent text-book for students, but also as a practical treatise for practical men."—*British Architect.*

"There has certainly been need for a book dealing with calcareous structural materials from the builder's and architect's point of view. Questions of the quality of lime and of cement, of the composition of mortar, of the suitability of diluents, such as sand and gravel, come frequently before the members of this trade and profession, who have to pronounce upon to the best of their ability. The author has succeeded in putting together a number of useful statements—especially to be commended is his dissertation on mortar. The section on asphalt, embodying Mr. Clifford Richardson's researches, will be acceptable."—*The Engineer.*

2143.—ANCIENT LIGHTS: OBSTRUCTION OF ANGLE OF LIGHT.—"Architect" writes:—"The owner of a garden C. proposes erecting a hoarding against the boundary-fence wall of a block of five houses belonging to another owner B. The tenants of these houses, whose backyards are only 8ft. 6in. in depth from houses to boundary fence, throw rubbish over the fence wall into C.'s garden, and C having determined to stop the nuisance caused by the tenants, proposes to erect a hoarding extending to a height of 4ft. above the top of the fence wall, which will be carried on iron standards independent of the fence. The top of the hoarding will be within an angle of 63 deg. from the sills of the cottage windows. Can C. erect the hoarding as proposed without being liable to B.? The boundary wall has been in existence as at present some 35 years."

Answer.—The querist evidently labours under the misapprehension that an erection placed at such a distance and height from an ancient light as to prevent the light falling on to the window at an angle of 45 deg. is sufficient ground to infer that the light is materially obstructed. The doctrine of the angle of 45 deg. has long since been exploded. Where any building has acquired an easement of light, and the light is subsequently obstructed by a new building or erection, it is immaterial whether the new structure is erected at an angle of 45 deg. or at a greater or less angle. The real point is to ascertain whether the easement has been acquired, and, if so, does the new structure obstruct the light.

2144.—SOLUTION OF FLUORESCEIN FOR TESTING DRAINS.—"W. W." writes:—"In THE SANITARY RECORD of August 14th last, page 158, an alkaline solution of fluorescein is recommended for testing drains. I should be greatly obliged if you would inform me where this may be obtained and at what price. Local chemists do not appear to stock it."

Answer.—Fluorescein solution is made by dissolving two grammes of fluorescein in 100 cc. of a 2 per cent. solution of potassium carbonate, and if not obtainable from a local chemist can be procured from Messrs. Francis Sutton and Co., chemists, Norwich. We are unable to state the price.

2145.—POOR RATE AND ASSESSMENT AND COLLECTION ACT, 1869: RATING OWNERS.—"Perplexed" writes:—"I own a house formerly rated at £8. Twelve months ago I signed an agreement brought to me by the Assistant Overseer to cover a period of three years (called compounding), thereby making me responsible for the rates whether occupied or not, in consideration of which they granted me a certain allowance upon each rate. Upon receiving my last demand note I find that they have raised my rateable value from £8 as above stated to £9 5s., debarring me from the privileges granted under the compounding arrangement, which does not apply to properties rated above £8. *Query.*—Can they violate the terms of the before-mentioned agreement in this manner and without formal notice?"

Answer.—As the rateable value of the house has been increased, the agreement has now no application. No notice from the Overseers was, it appears, necessary. In Norwood Overseers *v.* Salter (892), 2 Q.B. 118, an order of the Vestry had been made under Sec. 4 (directing the Overseers to rate the owners); and an owner had made an agreement under Sub-sec 2 of that section in respect of a house which at the date of the agreement was within the limit of rateable value prescribed by Sec. 3 of the Poor Rate Assessment and Collection Act, 1869. Subsequently a new valuation list was made, in which the rateable value of the house was raised above the prescribed limit. In the first rate, based on the new valuation list, the Overseers rated the occupier, who contended that the owner should have been rated pursuant to the order of the Vestry. The Overseers contended that the rate must necessarily follow the valuation list, and that the rateable value as it appeared therein at the date when the rate was made must determine whether the house fell within the prescribed limits of rateable value. Hawkins, J., said:—"In my opinion the true and reasonable view to take of Sec. 3 is, that it permits such agreements to be made in respect of any house or houses so long as it or they do not exceed the limited rateable value, but no others; and that agreements under Sec. 3 should be construed as having application to the hereditaments mentioned in them only so long as such hereditaments continue of a rateable value not exceeding the limited amount."

2146.—FORMS OF NOTICES BY SANITARY AUTHORITY.—"Inspector" writes:—"Will you kindly inform me whether the enclosed forms of notices and resolutions under Secs. 23 and 41 of the Public Health Act, 1875, will be in order, providing I can get my Council to pass same?"

Answer.—We advise the querist to procure the model forms under the Sections named by him, and published by Messrs. Shaw and Sons, Fetter-lane, London, E.C., with regard to notices, &c., in preference to the forms drafted by him. A catalogue of public health forms and notices will be sent by the publishers on application.

2147.—PROSECUTIONS UNDER MERCHANDISE MARKS ACTS.—"Inspector" writes:—"Can you tell me of an association that takes up prosecutions under the Merchandise Marks Act, such as, for instance, foreign butter sold as English, &c.?"

Answer.—We believe the querist will find the Trade Marks Protection Society, 1, Furnival-street, London, E.C., is such a society as that to which he refers.

J. & M. CRAIG, Ltd., KILMARNOCK

THE HOUSING OF THE WORKING CLASSES IN SCOTLAND.

By Wm. Robinson, M.D., M.O.H., Paisley.

It is recognised that the scope of the Acts at present in vogue is not sufficiently comprehensive and clear to enable Local Authorities to move with the freedom that they ought. Legislation is promised, it is true, but that is no reason why something should not be presently done.

Paisley stands in a peculiar light as regards the need for houses for the labouring classes. When one advocates the provision of better houses for the working classes, the very practical objection is placed in the way that there are numbers of houses to be had for the asking, and that their rents are no greater than the houses it is proposed to erect. I say that seems a most unanswerable objection; but let us approach it a little more closely. When we do so it will be discovered that a great part of the objection falls to the ground. First, we find the empty houses, of which there are not a few, devoid of the very benefits that new houses under a Corporation scheme would possess. For instance, there is bad amenity, faulty ventilation of the rooms, often an inadequate water supply, or a water supply common to several houses. The rooms, if ticketed, would not in many cases allow the housing of more than one or two adults, for they are small, low in the roof, and constructed to accommodate a box bed. The box bed in itself is one of the evils that encourages, by the defective circulation of air, pulmonary diseases. And lastly, there is no such a thing as a water-closet attached to the houses under description.

The mention of the boxed-in bed leads me to say a word upon this important feature; for this method of structure will be strictly barred in the artisan's house of the future. Not long ago I caused inquiries to be made regarding the character of the houses in which many of the deaths from tubercular diseases of the lungs had taken place. I found that in nine cases out of ten the patients had lain in dark boxed-in beds which were surrounded by hangings and curtains. In fact, every condition had been there to encourage the progress of the disease from which the patients were suffering. Medical men are only too familiar with the difficulties they have to contend against when trying to diagnose the nature of disease where the sick person is lying upon one of these dark and almost inaccessible beds. That these houses gain for themselves a bad reputation is not to be wondered at, nor is it a matter for surprise that so many of them are empty. I mention these facts to answer the argument as to the existence of so many empty cheap houses in the burgh. In connection with this inquiry that was made, the question of wages was also gone into. In not a few cases people were living in families of five and six in two-roomed houses, and the gross wage coming into the house every week was over £2. Even in the one-roomed houses the wages were found to be now and again about 30s. Therefore, if these people have this money coming in and are willing to pay £8, £9, or £10 for their houses, which houses have no modern sanitary provisions attached to them, how much more willingly will they pay the same money for a house that is fitted with every necessary convenience? I will at once be attacked, I have no doubt, for this free manner of speech and thought, because I am striking at the root of private enterprise. I am threatening to encourage people to leave their houses and to rob the landlord of his rent. If that suggestion is raised I can only answer it by saying that public health and landlords' interests are not synonymous terms. The Local Authority that desires to have a healthy town must look after the health of its citizens. That is the whole sum and substance of the matter at issue. I cannot but admit it seems hard that a man should spend perhaps hundreds of pounds in acquiring property so as to let the houses with a profit, and suddenly to discover that a Corporation is seeking to undersell him. For an answer to that again, I have but to point to Glasgow, where the Corporation enterprise as regards houses for the working classes has led private enterprise to go and do likewise. Private enterprise can always cope with any enterprise if it chooses to put its best foot foremost. Legislation and Acts for the better housing of the masses would never have been called for had private enterprise been maintained at a uniform level of excellence. It is the existence and the promise of further legislation that frees the Medical Officer of Health of all blame when he advocates improved dwellings for the labouring classes. It does so because it is a culpable neglect if the Medical Officer of Health fails to do his duty by his Local Authority as regards pointing out remedies for existing evils (Housing of the Working Classes Acts, 1890, Section 5).

The Act just quoted is divided into three parts; strictly speaking it is divided into seven parts, but for the present the first three are to our purpose.

Under Part 1.—Large areas and slums can be dealt with.

Under Part 2.—Individual houses can be made fit for human habitation, or failing that, they may be demolished. Obstructive buildings can be demolished. Small areas of unhealthy houses can be pulled down and reconstructed.

Part 3 refers to the erection of dwelling or lodging-houses for the working classes in districts where the same are required.

Having had the opportunity to discuss the matter with some of those intimately interested in this subject, I find that the inclination is to approach the subject in a careful manner. That is to say, there is no desire to leap into experimental darkness. The suggestions are eminently practical, and worthy of every support.

Therefore the adoption of Part 3 seems to possess not a few advantages.

First, the provision of dwellings overcomes the objection so frequently raised against the demolition of houses before others are raised in their stead. Some towns have fallen into that error with unfortunate results to the unhoused people. If, on the other hand, the houses are built, one will be in a position to select the future inhabitants of these houses from localities that are unhealthy by repute and experience.

Now there are one or two points that might be emphasised when dealing with the subject at the present time.

The first is the site of the proposed houses. That should unquestionably be on the outskirts of the town. In the first place that relieves congestion, and in the second place it means a vast difference in the future well-being and health of these people. Locomotion will soon be made easy and cheap to all parts of the town, so that the objection against difficulty of access will be easily overcome.

Secondly, there is the particular class of people to be dealt with, and that is a somewhat difficult problem. The feeling seems to be in favour of providing houses for the very poor. Houses, in other words, that do not cost any more than £4 a year of a rental. The object is most commendable, but to carry out the experiment to a successful issue, there should also be provision made for a number of two-roomed houses at a slightly higher rental. Now, one of the strongest arguments that will be levelled against the one-roomed houses for this very poor class of persons will be that if they cannot keep their present houses in a cleanly state, how are they to behave any better in the suggested houses? I think the answer is easy, though it will also meet with objection. The presence of a caretaker in each tenement will act as a sufficient guarantee that the houses and precincts will be kept in a proper state of order and clean-

liness. The objections that I have hinted at will be that by placing a caretaker over these people you take away their spirit of independence. I fear that line of reasoning will not apply to a class of people who require to be policed, practically speaking, into good conduct. In fact, they are the people who abuse the privilege of liberty by riding over the top of it. The presence of a caretaker can do no harm; he will do good. His absence on the other hand is certain to lead to neglect and slipshod methods of house cleaning. These houses are never meant to be charitable institutions. They are intended as the Acts imply to be efforts on the parts of Local Authorities to teach people how they may lead better and more healthy lives when provided with every means that is possible to make them healthy. Rents will be carefully collected, and backsliders must abide by the result of their sins of omission and commission. If the suggestion that a hundred different families are to be provided for is carried out, I would add the further suggestion that a percentage of these householders should occupy two-roomed houses at a rental of from £6 to £8.

In both classes of houses bath-room accommodation ought to be provided. The bath-rooms, as apart from the water-closet accommodation, would be common to the families on each stairhead. Say there were four on each landing, then there would be two baths for the four families. In the better houses there would be a bath in each house. Hot water could be provided from a boiler on the basement flat, and controlled by the caretaker. Arrangements could easily be laid down for the methodical supply of hot water, but only to the baths. The mind at once associates something very elaborate in connection with a bath-room. Practical men know, however, that a bath need not be a very costly thing. Its benefit no one can possibly deny.

I would impress very strongly upon the Local Authority the next point. This is with regard to the construction and disposition of the houses and tenements. All the doors should enter off galleries. There will be in that way no doors entering from a dark passage. Each door, too, will admit to a separate house. On no account should more than twelve houses be allowed in each tenement. Three flats will be quite high enough. To emphasise this feature I can state that Edinburgh is seeking in its new Bill before Parliament to restrict the future number of houses on a stair to twelve.

As a further improvement, it might be suggested that the roof of the tenement be rendered flat like the roof of an Oriental house.

Surrounded by a high iron railing, this would be a safe place for children to play, away from the dust and mud of the streets, as well as a useful spot to dry clothes belonging to the householders.

I can only conclude my remarks upon this very important subject by quoting from a speech made by Alderman Purcell, of Liverpool, at the last Congress of the Sanitary Institute, when this important subject of the Housing of the Working Classes was discussed. He said, "But in Liverpool they did go on the rates for 1½d. or 2d. in the £. And if it was necessary the Council would grant them 6d. in the £. If municipalties spent money on libraries, museums, parks, gardens, and infectious diseases hospitals, was it not fair and right that a few thousands should be spent in preventing infectious diseases?"

At the Shifnal Rural District Council last week, Dr. Whitaker, Medical Officer of Health, presented his annual report, showing satisfactory conditions in the district. Estimates for the ensuing year on account of highway expenses were adopted as follows:— Shifnal, rural district, £2257; Shifnal, special drainage district, £362 10s.; Blymhill rural district, £316.

Local Government Board Reports.

The Sanitary Administration of Boston.

The borough of Boston, Lincolnshire, judged from the impressions gained in the course of "flying visits," and now by the reading of Dr. S. Monckton Copeman's report on its sanitary condition, provides an apt illustration of the old adage that "things are not what they seem to be." To the casual observer the borough presents a cleanly and healthy appearance, more particularly in the main thoroughfares. Even the by-streets are tolerable, except for those who have tender feet, which affliction makes a journey across the cobbles a weariness to the flesh. But behind all this apparent cleanliness there lies a laxity of administration which is fraught with the gravest danger to the inhabitants. The truth is there is an utter lack of municipal spirit, or perhaps it would be nearer the truth to say that years ago, what enterprise the governing powers possessed exhausted itself in "Boston's folly"—the docks—and since then every other need of the town has been starved.

Some years ago Dr. Bulstrode had occasion to visit Boston during the progress of the cholera survey, and reported unfavourably on the drainage, sewerage, refuse removal, and water supply. Following this report, the Local Government Board ordered an inquiry, and sent down a series of recommendations to the town, but after a lapse of seven years scarcely any effort had been made to carry these into effect, and so another inquiry was ordered, and Dr. Copeman was sent down last year.

The estimated population of Boston is about 16,000; the area of the borough is 2688 acres, and the rateable value £47,240. At the outset of Dr. Copeman's report, he seems to imply that the weak spot in the administration of the town is found in the Surveyor's department. He incidentally observes that within the past five years 235 houses have been built. "There is," he remarks, "supposed to be supervision of building operations by the Surveyor's department, but seeing that no record of inspections is kept, and that no certificates are issued, notwithstanding a bye-law requiring that new buildings shall not be occupied before such certificate has been granted, it is difficult to judge whether these duties are carried out in other than a perfunctory manner."

Dealing with the various sanitary works, the water supply is first noticed. This is secured from a gathering ground at Miningsley, some twelve miles from the town, and about 120ft above it. The reservoir is capable of holding, when full, about 75 million gallons. The waterworks, which are owned by a private company formed in 1849, include five filter beds—four old ones, and a fifth larger one, recently added. Each of the four smaller beds measures 49ft. by 63ft., and 6ft. in depth; the fifth bed measures 102ft. by 52ft., and is 7ft. deep The filtering material in the older beds consists of layers of gravel of varying degrees of coarseness for a total thickness of 2½ft., above which there is a layer of sand of an average depth of 2½ft. The larger bed has similar layers of sand above and gravel beneath, but the total thickness is somewhat less than in the other filter beds. Beneath the gravel, however, are two rows of cellular brickwork, 6in. in depth. The sand used is obtained from the river Trent, and is washed before being laid down in the beds. The Inspector was informed that the surface of the sand in each filter is scraped about once a week, and that the whole filtering material is changed yearly. Dr. Copeman reviews the steps taken to test the quality of the water. On the whole these were satisfactory, but the mains are laid too near the surface, and in the summer the water is delivered to the houses at 67 deg. Fah. The manager of the works is well spoken of, and there are signs of

further improvement being made, so that a better quality of water is gradually being secured.

The sewerage system is divided into two parts—east and west. There are some peculiarities in connection with the working of this branch of the administration which may be of interest to our readers. East of the river, the sewage of the more central and oldest part of the town discharges to an ancient sewer called the Barditch. This was originally uncovered from end to end, but it has gradually become covered in by the owners of the property through which it passed, so as to enable buildings to be erected over it. This having been done on no definite system the dimensions of this sewer vary considerably at different parts of its course, while for the most part the bottom is very uneven, and the sewer has no regular fall. At intervals along its course are large catch pits, the periodical emptying of which is not only a matter of considerable expense, but often of much annoyance to persons living in the neighbourhood. This sewer is under the control of a body termed the Court of Commissioners of Sewers; the Sanitary Authority of the borough, curiously enough, having as such, no voice in its management, although members of the Town Council are *ex officio* members of this Court. On an official of this Court, known as the Dykereeve, devolves the responsibility for the condition of the dykes and sewers under their charge. Surely this is one of the relics of antiquity that might easily be dispensed with. The working of the Barditch sewer is described in detail. One fact is particularly noted, viz., that it is unventilated, and, as a consequence, when the manholes are unsealed, or the sewer head opened, very foul smells are complained of.

There is still another drain on the east side, which is called the Maud Foster (Bargate) Drain. This appears to be quite inadequate for the demands made upon it; but the unique control has prevented any improvements being carried out, notwithstanding that they have been advocated for over forty years. A dog-in-the-manger policy has been pursued. First, the Urban Authority would propose something. This did not satisfy the Rural Sanitary Authority, which would suggest another scheme. Neither would give way, and so the nuisance has dragged on.

What the West Boston sewerage is like may be gathered from the following extracts:—It commences in Carlton-road, passes through Fydell and Irby streets on to King-street. From this main line branches have been made from time to time; manholes are placed at given intervals. Beneath each manhole the floor of the "sewer is deepened to form a catch-pit for solid matter, which, as I was informed, is cleared out 'from time to time.' No ventilating shafts have been erected along the course of the sewer, as the Surveyor has advised the Sanitary Committee that they enable the effluvia to escape 'more on a level with the bedroom windows of houses,' adding, in a report to the Committee, that he had found it impossible to obtain suitable sites for their erection. Recently manhole covers have been made air-tight, and sewer air, especially when under pressure, through the outfall being blocked, is likely to escape into the houses. So likely is this to happen that the Sanitary Committee now suggest that it would be better to 're-open the manholes, and endure the occasional smell arising from them, than run the risk of sewer gas escaping into houses through improperly-trapped drains.'"

After describing the flushing arrangements, Dr. Copeman says that "the tank at the head of the sewer which passes down Sleaford-road was, at the date of my visit opened, and the cover of the manhole nearest below it was also removed. As a result, a most objectionable smell asserted itself, making my inspection of the interior somewhat difficult. The catch-pit at the bottom of this manhole was full of semi-solid matter, which extended into and half filled the sewer itself. On the discharge of the contents of the flushing tank, no appreciable disturbance of this semi-solid deposit had occurred after an interval of ten minutes, when observation was discontinued. The flushing tank in Sydney-street was said to be out of order. In Carlton-street an experiment in flushing on a gigantic scale, independently of the flushing tanks, had just been carried out under the supervision of the Surveyor. Water from large clay pits had been pumped by steam power for a fortnight into the sewer at a manhole where, by blocking up one or other of the sewer openings, the water could be made to pass along either to the right or left, the sewer being practically level at this point. As the result of the influx of so large a quantity of water (at a cost, as the Surveyor informed me, of about £20) this sewer was free from deposit between the manhole and the junction of the sewer with the one in Sleaford-road."

Some manhole covers were removed for inspection. "In the former sewer, I found the accumulation of stagnant sewage so considerable that it was impossible to see either the inlet or outlet of the sewer. The surface of the sewage was covered with bubbles, and the smell was most offensive. In Irby-street also I found the manhole full of stagnant sewage to within about a foot of the road surface, although at the time the tide in the Haven was quite low. In short, the greater portion of the sewerage system on the west side of the town has come to constitute what is practically a gigantic cesspool, the contents of which, under existing circumstances, are never completely removed, and consequently undergo putrefactive changes *in situ*, the gases resulting from these processes finding an exit as best they can, either through or around the manhole covers or to the interior of houses. Evidence that the sewers leak in places is afforded from time to time when the roadway is opened up for any purpose near the main sewer or one of its branches. This was particularly evident early in the present year, when the ground in Granville-street was opened for the purpose of laying water pipes. In this particular street the sewer, as I am informed, always stands full, or nearly so. On this account house drains discharging to this sewer have been so laid as to enter the sewer at the top instead of at the side, as would be the case under ordinary circumstances."

With regard to excrement and refuse disposal, water-closets with flushing apparatus proper, are comparatively few in number in Boston. There exist, however, some 150 closets unprovided with any proper water supply for flushing purposes, the reason given being that the charges of the water company for the installation of a cistern and its accessories, and for the use of water for closet flushing are prohibitive. These "hand-flushed" closets are commonly very foul.

With the above exceptions, "ash-bin" closets are almost universal in Boston. The type of those closets approved by the Town Council consists of a combination of privy and ash-bin. In the ash-closets on certain premises the vaults were full up to, or even above, the level of the seat; in other instances, the vaults contained a considerable quantity of fluid. It is thus apparent that arrangements for the removal of the privy contents are inadequate. Collection and disposal of refuse from these closets is a task of considerable magnitude. The quantity of material collected amounts, according to the Surveyor's estimate, to about fourteen one-horse loads daily, or an average of from 4200 to 4300 per annum. Formerly, the material collected was in considerable demand with farmers and market gardeners in the neighbourhood, and the refuse was readily disposed of at a price of from 2s. to 2s. 6d. per load, delivered free.

At present, the material, consisting of fæcal material mingled with a certain proportion of ashes, together with potato peelings and other household refuse, such as old tins, boots, paper, &c., is carted outside the

town, for distances varying from one to two miles, and tipped into disused brick pits. Concerning these dumping grounds, the Medical Officer of Health says in his annual report for 1899:—"An intolerable nuisance is created in almost every outskirt of the town by the accumulation of huge heaps of refuse and garbage, deposited by the Sanitary Authority and allowed . . . . to remain for months, pouring out the most sickening smells. During the summer and autumn, many houses are almost uninhabitable, being invaded by myriads of flies, which are bred upon these putrid heaps of filth."

To secure abatement of the nuisance from the present method of disposal of the town's refuse, the Medical Officer of Health recently suggested to the Sanitary Committee the advisability of erecting a destructor. The Committee have expressed the opinion that difficulty would arise from a destructor having to be placed some distance away from the town, and that in whatever spot it were placed, a very great nuisance would be created by the succession of carts delivering refuse to it, and they say that they have not succeeded in finding any place where they think a destructor could be used without being objected to by the surrounding inhabitants. The Inspector ascertained that the Surveyor was aware of no less than six possible sites, of which one appeared to possess certain special advantages, in that it is situated in the lowest part of the west side of the town, and so would make a convenient site for a pumping station for lifting the sewage from the district where the drainage at the present time is most defective. Power for pumping sewage, or for generating electricity, could be rendered available by the consumption of the refuse.

After referring to other sanitary conditions, Dr. Copeman has some strong remarks on the manner in which the bye-laws have been administered. He says:—"The question of bye-laws having been referred to by the Medical Officer of Health, in his annual report for 1899, the Sanitary Committee in their published criticism of that report, say:—'Your Committee have considered sometime since the advisability of fresh bye-laws. The present ones are old, but the Surveyor advises the Committee that they are sufficient.' . . . In another section of this same report, the Committee say, in reference to the question of certain sanitary defects in houses to which the Medical Officer of Health had called attention:—'No certificate of completion had been given by the Surveyor,' intimating that the Medical Officer had been unduly hasty in reporting on the matter, since a bye-law exists to the effect that no new dwelling shall be occupied until the Surveyor shall have given a certificate that all the sanitary and other arrangements have been carried out in accordance with regulation. Being desirous to obtain evidence as to the manner in which the present bye-laws, considered by the Committee, on the authority of the Surveyor, to be sufficient for all purposes, are enforced, I took as a test case the question of building certificates, and applied to the Surveyor to show me the counterfoils of such certificates as had been issued during the past five years. During this period about 235 new houses, as he informed me, have been erected in Boston, but except in a single instance no 'certificate of completion' had, I found, been issued by him during the same period. The exception occurred in the month of May, 1900, when a certificate was issued in reference to a house now in the occupation of the son of the Medical Officer of Health. Only seven certificates had been issued during the last thirty years, yet a considerable penalty (£5 and £2 per diem during default) is supposed to be inflicted on persons occupying a house in respect of which such a certificate has not been issued. In this connection, also, it is of interest to learn that the Committee in their own words 'have never yet had before them a case in which the present bye-laws have not been sufficient to enforce any liability they have thought necessary.' The Town Clerk was only able to tell me of a single instance in which a penalty had been inflicted for contravention of the building bye-laws.'

The isolation hospital is an illustration of "how not to do it." In 1881 an old farm house, situated about one and a-quarter miles from Boston, and about a quarter of a mile from the docks and landing stage, was acquired as an isolation hospital, for the joint use of the Urban, Rural and Port Sanitary Authorities. It contains four rooms intended for use as wards, a bedroom for the caretaker and his wife, and a large and airy kitchen, which is also used as a living-room. The hospital, although well isolated from other buildings, is too near the public roads. On the same site there is in addition a small brick building erected in 1893, which is known as the small-pox hospital. This building is damp. It has no furniture, and there is no closet accommodation. Attached to the farmhouse building are a couple of ash closets, which I found in a filthy condition. There is a building which does duty for a laundry, and several out-houses, one of which contains an old and clumsy ambulance; but this is shortly to be replaced by a more modern and convenient conveyance. There is no mortuary. Rain water is stored in an underground tank and pumped up for use in the hospital. The caretaker informed me that it is usually very dirty, and has an exceedingly unpleasant taste. For drinking, it is now always filtered through a Berkefeld filter. Slop water passes to a cesspool, which is emptied occasionally. A labourer and his wife live on the premises as caretakers, for which they are paid £30 per annum. When there are patients in the hospital the man is paid an extra 15s. per week, and the woman is paid 3s. a week for each patient up to a limit of 12s. for acting as nurse. She has not had any hospital training. Hitherto, the various Authorities concerned have not provided a trained nurse, although private practitioners who are allowed to attend their own patients in the hospital, have on occasion, installed an efficient nurse in charge of such cases. This arrangement has been productive of friction, owing to the respective duties of the nurse and the caretaker's wife in such instances not having been accurately defined.

In conclusion, Dr. S. Monckton Copeman, makes the following recommendations:—

(1) The Town Council should at once carry out a comprehensive scheme for the efficient sewering of the town.

(2) The Town Council, pending the general adoption of water-closets, should adopt an improved system for the disposal of excrement and other refuse.

(3) More extensive provision than at present exists should be made for the isolation of cases of infectious disease, in view of the fact that the farmhouse, which now serves as the isolation hospital, in addition to having to meet the demands made upon it by the urban sanitary district, has further to provide for the wants of a population of about 25,000 in the rural sanitary district, and an unknown number from the shipping of the port. The present administrative arrangements should be improved, and mortuary accommodation should be provided at the hospital.

(4) The Town Council should, as speedily as possible, provide an efficient apparatus for the disinfection of infected articles and clothing.

(5) The Town Council should, under the advice, and with the assistance of their Medical Officer of Health, revise and extend the existing bye-laws, and bring them, so far as the special circumstances of the district permit, into accordance with the model series issued by the Local Government Board.

(6) The Town Council should draw up and submit to the Local Government Board regulations under the Dairies, Cowsheds, and Milkshops Order of 1885-1886, in accordance with the powers conferred upon them by Section 13 of that Order.

THE PROBLEM OF INDIAN TOWNS.

Any man who has been through an Indian town or an Indian village, says a writer in the *Madras Times*, even if an habitually unobservant man, cannot but have noticed under what frightfully insanitary conditions the greater part of the inhabitants, even those of the well-to-do classes, and much more so the poor and labouring classes, exist. His eyes and his nose must have had their attention forcibly and disagreeably called to this distressing fact nearly a hundred times in every hundred yards of his journey. Madras is in this respect particularly bad. The streets and the roadside drains in the early mornings provide truly abominable tableaux. Particularly bad is the state of affairs in the larger townships of this far-stretching city. We will attempt no description. A hint must be more than enough, for the facts shout aloud for attention, along even the chiefest of our great roads in the best quarters of Madras. Everyone knows, everyone is unfortunately forced to observe. Only the police, whose duty it is to take cognisance of these offences against the health and proprieties of the settlement, have the enviable power of being able to shut their senses to the facts. Things are abominable in Black Town, New Town, Vepery, Triplicane, Mylapore, and all the thickly-populated portions of the city, but they are only a little better in Egmore, Teynampet, Chetput, and the other open European quarters, where each house is built in a park. All through these beautiful quarters are scattered parcherries and townlets of varying sizes, hiving on the edges of the main roads, and each one is a plague spot, where the very ground has long rotted beyond rottenness with uncleanly things. In the midst, and on top of all this hideous filth, the people swarm and work, eat and sleep, are born and die. Fortunate indeed is it for Madras that it is a "City of Distance!" Lucky the European inhabitants who grumble at the fact that it is a day's work in driving to make a round of half-a-dozen calls! Were it not for this the new cemetery at Chetput would soon be the most thickly-peopled part of the town, and the Municipality be forced to take up another park for the army of those who have gone to the majority. So far from grumbling at the prevalence of fevers and the height of the death-rate, we should rather wonder how Madras remains as healthy as it does. Considering the inexpressibly filthy habits of the majority of the lower class dwellers in Madras, their sublime contempt for sanitation and the regulations, the difficulty of draining the place, and the festering sites on which the townships stand, it is simply astonishing how wonderfully, and undeservedly, healthy the city is. When the average man sees the pigstyes that go to make up the greater part of this place he almost wishes for the advent of a second Lally, followed by an army of plundering camp followers, so that the horrors might be burned out and the place cleansed by fire. It is to him a source of constant wonder how human beings can continue to exist, much more grow fat and lusty, as the people of Madras and other Indian cities do, when their lives are a constant violation of nearly every condition of sanitation and hygiene. He is forced to attribute it to the great sweetener sun, and the constant open air life of most of the people, and to think the people fortunate, in that the pestilences that sweep the land regularly have not long since slain every living thing in India. The people will not improve the conditions under which they live. The greater majority have no desire for anything better, even if it be provided for them. They have no idea of decent cleanly living, let alone the advantages to themselves and their neighbours to be derived therefrom. If they are disturbed, and some of the filth in which they wallow scraped away, they object, and talk of the violation of privacy and the injury done to their religious susceptibilities. Since the plague, essentially a disease of filth, first appeared, thousands of lives, and millions of money, have been sacrificed, and will continue to be sacrificed, till the sanitary conditions of Indian cities are greatly improved. This is a thankless task and hard. The people will not dream of improving matters themselves. It is not so much that the majority are too poor to improve the conditions under which they live as that they are too utterly indifferent. They know, and desire, no better. The landlords are as bad or worse. Things must, however, be improved. The industrial conditions of India are changing, quite apart from the enormous, and steadily continuing increase in the population the establishment of the British peace has brought about. Although still mainly an agricultural country, India is rapidly being studded with great manufacturing and industrial centres. Little open towns are becoming great cities crowded with workers, and the housing and health of these workers is becoming a subject of the primest importance to the nation. The present conditions under which the lower classes in our great cities live are dangerous and undesirable to a degree, they must be improved, and that at no distant date. The workers hate improvement, and we must make them learn to at least tolerate, if not to welcome it. There is the problem, a difficult one it is true, but one which must be solved.

IN FAVOUR OF ABATTOIRS.

The Medical Officer of Health for Wigan, Dr. William Bury, has issued a report to his Corporation showing the necessity of providing a public slaughter-house. He mainly bases his recommendation on the following arguments summarised by Dr. Harris, Medical Officer of Health for Islington:—

I.—Hygienic Reasons.

(*a*) The erection of such buildings would remove nuisances from the neighbourhood of dwelling-houses.
(*b*) Putrifiable matter would be excluded from the sewers.
(*c*) Meat would be protected from liability to exposure from foul emanations.
(*d*) Thorough examination of all meat for disease would be ensured.
(*e*) The traffic in diseased meat would be materially limited.

II.—Economic Reasons.

(*a*) Less liability of the meat to spoil because slaughtered under better conditions.
(*b*) More blood and offal would be saved.
(*c*) There would be a saving from order, the proper division of labour, avoidance of driving animals through the streets, and the doing of business on a large scale.
(*d*) Abattoirs properly managed yield a fair profit.

III.—Humanitarian Reasons.

(*a*) Much of the cruelty to animals that now occurs would be put an end to, owing to the use of improved appliances for slaughtering.
(*b*) The driving of weary and exhausted cattle through our streets would be avoided owing to the abattoirs being situated near railway stations.
(*c*) The street danger to the public would be greatly lessened.

Provisonal Orders have been granted by the Board of Trade for the supply of electricity to the Local Borough Council and the Marylebone Electric Supply Company, in order that both may be incorporated in a confirming Bill and considered by the House of Commons.

THE NEED OF WOMEN SANITARY INSPECTORS.

A MEETING, which Mrs. Mylne (Paddington Guardians) was instrumental in organising, was recently held at Paddington Town Hall to hear an address on the question of "Women as Sanitary Inspectors," by Miss Alice Busk, Guardian of the Poor, and member of the late Vestry of St. George the Martyr, Southwark, an Authority which had three women Inspectors upon its staff. Alderman Colonel Blair (Paddington) presided over a good attendance.

In a few preliminary remarks, the CHAIRMAN said Miss Busk had come to Paddington to convert them as to the necessity of appointing lady Sanitary Inspectors. Personally he had not yet been "converted." There were many districts where lady Inspectors were positively necessary. In Paddington they were mostly retired people and well-to-do, and the proportion of poor was very small, so that the need did not so much exist there. If Miss Busk wanted to convert Paddington it was the right time to do so, as the Borough Council were considering the constitution of their staff, and the Committee would no doubt take into consideration the appointment of a lady Inspector. The Mayor (Sir John Aird, M.P.), and Sir George Harris (chairman of the Public Health Committee), favoured the proposal, and their able young Medical Officer of Health, Mr. Dudfield, had got all the desirable luxuries he could for them. It was for Miss Busk to prove whether lady Inspectors were a luxury or a desirable luxury. They in Paddington had always wanted women workers. There was a difficulty some years ago in getting ladies on to the Board of Guardians, but at the last election five ladies were elected, which, he thought, was very satisfactory.

Miss BUSK gave a lucid and interesting address, showing in many ways the necessity of women Inspectors, such as visiting workhouses, factories, warehouses, &c., where women and girls are employed; in visiting tenement property, and giving instructions to women as to the proper feeding of children, cleanliness, ventilation, &c.

Mr. TREHAWKE DAVIES (chairman of the Public Health Committee of the Marylebone Borough Council), in the course of a few remarks, referred to Miss Busk having quoted Marylebone as having one lady Inspector, and that she was paid the lowest salary of any Sanitary Inspector. Personally, he did not think they paid her half enough. She was a most invaluable acquisition to Marylebone, and gave every satisfaction. He only regretted that each Council in London had not half a dozen Sanitary Inspectors.

Dr. PRINCE, as a member of the Paddington Public Health Committee, also addressed the meeting at some length, and referred to the fact that no less a sum than £125,000,000 had been spent in town and country in order to improve sanitary science, and to put them on a better footing as regards hygiene. But, up to the present, they were very imperfectly informed on sanitary matters in general. Landlords had difficulties. Landlords were sometimes a class to be pitied. (Hear, hear.) They might get undesirable tenants who would spoil the best of houses. As regards a female Inspector, he thought it would be a very wholesome introduction to any Borough Council. Women were possessed of more patience and more persuasive power, and they would be very useful in educating people up to sanitary reform. People did not like reforms arbitrarily thrust upon them. Women would be able to show women what ventilation and cleanliness would do in improving comfort and health. He should be sorry to see the male Sanitary Inspector superseded. The introduction of women was not likely to lessen their popularity, but to supplement their good work.

Ald. REDMOND bore testimony to the good work being done by the women Sanitary Inspectors in Southwark, and in the course of an eloquent address said that so long as they had poor people they would have ignorance, and so long as they had ignorance they would have a low standard of sanitary knowledge, and with that a higher death-rate. He thought there was just as much need in Paddington for lady Inspectors with its many business houses where women and girls were employed. If the work of women Inspectors was to be a success, it was desirable to have women as members of the Borough Councils, to superintend and help them.

Mrs. MYLNE refuted Col. Blair's inference that there were very few poor people in Paddington. Although it was a rich parish there were some poor districts in it as would bear comparison with any in London, as the Board of Guardians knew too well. She thought a lot could be done in the way described by Miss Busk in teaching poor women who were absolutely ignorant of the laws of health. She had received letters of regret at inability to attend from Mr. E. Boulnois (Mayor of Marylebone), Dr. J. Fletcher Little, L.C.C., Lady Battersea, and Mr. Rodwell Johnson, all expressing sympathy in favour of the proposals. She (Mrs. Mylne) in supporting Miss Busk's arguments, thought that a woman could get access to houses where poor people lived when a man could not. And it needed a woman's sympathetic nature to bring about the improvements they hoped for. It had always been her feeling that what they wanted was the co-operation of men and women. It should not be one sex. They worked harmoniously on the Board of Guardians, and she would like to see the principle carried out in all departments of municipal life.

Dr. DUDFIELD (Paddington Medical Officer) said he had had no experience of women Inspectors, but he knew they had been extensively tried, and he could not recall an instance where they had been pronounced a failure. He thought that one objection might be that women object to being criticised by women. He pointed out that one-sixth of the children born died under one year of age. He attributed this "slaughter of innocents" to the ignorance of mothers in feeding. He thought women inspectors might do something in regard to cookery, and making suggestions to poor people. This he thought would do a lot to stop drinking. A great deal of drunkenness among the lower classes was due to the lack of good food at home. As regards the poor in Paddington he had noticed in some districts a change for the worse. He supported the appointment of women Inspectors, thinking there was a need of great activity in regard to public health.

The Rev. J. DIXON added his testimony as to the ignorance that existed among poor people, and the need of a woman to influence a woman. He moved a vote of thanks to the chairman, Miss Busk, and the speakers.

Miss BUSK replied, and having answered questions, the meeting was brought to a close.

ANNUAL REPORTS.

Blaby R.D. — Dr. Coles' annual report on the health and sanitary condition of this district states that the population estimated to the middle of 1900 was 16,660. The birth-rate was 25·8 per 1000, death-rate 13·8, zymotic death-rate ·90, and infant mortality rate 109·0 per 1000 births. In the three previous years the rates were:—1899: 26·9, 12·6, ·97, 115·1; 1898: 28·8, 14·2, 1·1, 114·8; 1897: 31·0, 16·7, 1·9, 136·8. There was a continuous fall in the birth-rate since 1897, and it was now considerably below the average for the last ten years. The death-rate, whilst higher than that of the previous year, was well below the average for ten years. The zymotic death-rate was again low, in spite of much measles and whooping-cough in the district. There were 15 deaths from infectious diseases, and 62 from diseases of the lungs. Certificates notifying infectious diseases numbered 122. Of 66 cases of scarlet fever notified there was but one death. The only village in which this disease was epidemic was Kirby Muxloe, but there was no death there. Of diphtheria and membranous croup 18 cases were notified, one proving fatal—a very low mortality indeed. Seeing the extent of diphtheria at Leicester, it was a matter for congratulation that so little disease had occurred in the rural district. Water supply: In neither Countesthorpe nor Whetstone was a good water found, and the officer regarded Countesthorpe as being supplied with water in the worst possible manner. The Corporation of Leicester had recently extended their supply to the Cottage Homes, and he recommended that a further application be made to the Corporation for a supply to the village. Drainage: There could be no doubt as to the necessity of a sewage scheme for Blaby. The scheme proposed by Mr. Simpson had been found too expensive to suit the Blaby Parish Council, and the Sanitary Inspector had been asked to prepare plans for an alternative scheme. At Cosby, which was in a filthy condition, the scheme proposed was that known as the Cosham tanks. At Kirby Muxloe the scheme was completed, and nearly all the connections were made. At Oadby the scheme was entirely completed. For Narborough plans had been prepared. At Enderby work was in progress, and it was expected to be completed during the year. Isolation hospital: The management had been reorganised, and, in the Doctor's opinion, vastly improved.

The Sanitary Inspector's report shows that 74 building plans had been examined, and 72 approved. The sewage works at Oadby and Kirby Muxloe were working satisfactorily and discharging a good effluent. Scavenging, on the whole, had been performed in a satisfactory manner.

Kidderminster—Dr. David Corbet, the Medical Officer, and Mr. J. T. Cowderoy, the Sanitary Officer for the borough, have presented their annual reports to the Town Council. The reports indicate much activity to promote the health of the inhabitants. Mr. Corbet reports 600 births during the year; 299 males and 301 females, with 542 deaths: 294 males and 248 females; deaths in the Workhouse: residents, 63; non-residents, 24; deaths in the Infirmary: residents, 27; non-residents, 19. The ages at which the deaths occurred were: under 1 year, 103; between 1 and 5, 50; 5 and 15, 20; 15 and 25, 23; 25 and 65, 181; 65 and upwards, 165; death-rate, 21·68. The number of deaths from zymotic diseases was 46; diphtheria, 17; measles, 16; diarrhœa, 7; whooping-cough, 3; scarlet fever, 2; typhoid fever, 1. Measles was not now notifiable, but upward of 300 cases came to the knowledge of the officials, and several schools were temporarily closed. Forty cases of scarlet fever, mostly of a mild character, had been dealt with. Twenty cases of typhoid fever were reported. The number of cases of diphtheria was 75, against 43 last year. The sanitary arrangements in most cases were in good order. Many of the houses in which cases occurred were quite new, some of them having been built on made ground. No death had occurred at the Borough Hospital during the year. With regard to slaughter-houses, Mr. Corbet believed that it would be to the advantage of the public and butchers if public slaughter-houses were erected. The cleansing and flushing of the sewers had received constant attention. Two hundred and thirty houses were reported as dirty. Mr. Corbet hopes that the work in connection with the additional water supply will be pressed forward, pointing out that an intermittent supply is attended with danger. The death-rate was highest in January, when it reached 41·60, and the lowest in October, when it stood at 14·04, and it is somewhat singular to state that the birth-rate was also the lowest in October.

Mr. Cowderoy, the Inspector of Nuisances, in his report, states that the number of bakehouses under inspection was 55; number of persons registered for the sale of milk, 51; as cowkeepers, 10; common lodging-houses 5, capable of accommodating 151 persons. The seats for Shop Assistants Act is well complied with. In most of the large places of business fixed seats are provided behind the counter, in others chairs are kept; workshops under inspection, 227; canal boats inspected, 259. The "Eclipse" smoke testing apparatus for testing house drains had worked well. The butchers' shops, also the provision, fish, and fruit shops and markets, had received continuous attention. The following summary of work done in the sanitary department indicates considerable vigilance:—Samples of food procured for analysis, 64; nuisances found, 1464; drains and water-closets opened by court sweeper, 939; notices served to abate nuisances, 903; school notes served, 567; circulars served, *re* consumption, 31; infectious disease, cases visited, 386; cases removed to hospital, 22; houses disinfected, 126; gallons of disinfectant given away, 125; loads of house refuse removed, 60; ashpits cleared, 3393; privies and middens cleared, 529; portable receptacles cleared, 61,360; loads of embers procured from refuse, 56; loads of manure sold, 38; cash collected, £248 13s. 11d. Mr. Cowderoy has also taken daily meteorological observations at the station on Prospect-hill. The highest temperature occurred on July 19th, when the thermometer stood at 89·6 in the shade, and the lowest temperature was on February 10th, 13·8, the mean annual temperature being 48·5. March is popularly supposed to be the most windy month in the year. The statistics, however, do not bear out the idea. The wind velocity was less last March than almost any other month, 3003 miles being recorded, while in December the register indicated 5086 miles. February was the coldest month last year.

Shildon.—The annual report of Dr. Fielden, the Medical Officer for Shildon Urban District Council, has just been issued. It shows that the birth-rate for the year was 28·8 per thousand of the population, as against 31·9 the previous year. The death-rate was 15·3 per thousand, as against 16·5 the previous year. The deaths under one year of age were equal to a rate of 4·48 per thousand. The zymotic death-rate was 1·47 per thousand, as against 2·16 in 1899. The report goes on to say that the general and zymotic death-rates were very satisfactory, the former being 3·3 less than the county rate, and three less than that of England and Wales. The infantile mortality was 12 below the county, and one above the whole of England and Wales. Speaking of scarlet fever and isolation, the Doctor says there is, doubtless, a very great and deeply-rooted objection on the part of the public to

allow their friends to be removed to the hospital, but as time goes on this will be less marked, and they will avail themselves of the benefits of the institution. In the meantime, however, when a case occurs in a house where there is no reasonable accommodation for isolating the patient, he thought the Council should issue some definite instructions to the Surveyor to resort to the necessary legal measures to enforce removal. Sixteen cases of scarlet fever were removed to the hospital. Eighteen cases of enteric fever were notified during the year, and in ten cases the patients were removed to the hospital. There was no reason to suspect the water or the milk supply in any case as responsible for the outbreak.

Smethwick.—A summary of the work in the health department during the past year has been prepared by the Inspector (Mr. J. Fyles). One of the chief features which presents itself is the sanitary improvements which have been effected in every department, not only in premises, but also in thoroughfares and streets. A total of 1664 notices have been served; 1173 bearing on sanitary matters, while 4000 inspections and re-inspections were made. These have resulted, among other things, in the abolition of various nuisances, and securing permanent sanitary improvements. A summary of the number of conversions into water-closets is given, and this, more than anything else, shows the success which has attended the Council's endeavours to do away with the old privies and middens. The Inspector says that during the year some very objectionable nuisances have been considerably reduced and obliterated by the alteration at several of the large works, while others had decided to put in new systems and abolish the old. It is gratifying to note that similar work has been effected in several schools, and there are now only three which have not made the alteration. He gives a list of twenty-five streets which are nearly exempt from privies and middens, and refers to the nuisance caused by the cumbersome and clumsy method of depositing the nightsoil in the street. The water-carriage system is not only incomparably more sanitary than the foul midden, with all its attendant evils, but is less expensive, and only requires an ample supply of water to ensure success. The Inspector, in a concise table, shows the number of privies and middens up to last July, at which time there were 10,885 houses in the borough. There has been particular attention paid to infectious diseases, and in each case preventive measures have been adopted. There are fifteen slaughter-houses in the borough, eleven being registered and four licensed. The cowsheds number nine, and the milkshops 123. The bakehouses number thirty-eight, and all these have been periodically inspected. The total cost of collection and disposal for the year of the whole of the nightsoil and dry refuse was £3906 4s. 10d. In further details Mr. Fyles says that on the average a privy costs about 8s. per annum in collection and disposal of contents, while in the transformed system, with a portable bin and frequent systematic removal, 3s. 3d. is the annual cost. It is obvious, therefore, that the dry system is not only the most economical, but what is of higher importance, the most sanitary. The boating away at 1s. 10d. a ton is responsible for a considerable item. A vast proportion of the dry and unoffensive contents of the middens, which was originally boated away, was, by the initiation of the chairman, disposed of to a tip in order to effect a saving of expense. From a sanitary point of view also this answered admirably. When the whole of the night soil and dry refuse were disposed of by boat, the cost of this alone averaged £105 per month, against £59 at the present time—a saving of £46 per month for the last fourteen months. There had been four samples of water submitted during the year—three from wells and one from a tap. The latter was certified to be pure, and only one of the others could be condemned, with the result that tap water was at once provided. Wells having been found to be contaminated had been gradually reduced, until at the present time they number eighty, supplying about 207 houses, an increase for the year of 738 houses with tap water. The Canal Boats Act had been enforced, and 129 boats had been inspected, in which the Act and regulations were complied with in 94·6 per cent.

Thrapston.—In his annual report on the health of the Thrapston district, the Medical Officer (Dr. C. W. Elliott) states that the birth-rate has increased from 21·1 in 1890 to 24·4 in 1900, this in spite of the fact that the birth-rate all over England had diminished. The death-rate, which had fluctuated a good deal in the ten years, ended by being almost exactly the same in 1900 as it was in 1890. Great improvements had been effected in sanitary work, the drainage of most of the villages having been much improved, and the houses most carefully inspected. The total number of deaths for the entire district during the year 1900 was 170, giving a death-rate of 14·8; of these 72 were among persons over 65 years of age. The total number of births in the whole district during the year was 280. With regard to the Northamptonshire portion of the district the officer reported:—The population of this part of the district is given at 10,546. The number of deaths during the year 1900, including 11 deaths in the workhouse, was 160, giving a death-rate of 15·17. The sewage disposal works at Thrapston are approaching completion. This scheme, which is expensive, will stop pollution of the river, but does very little for the sanitary requirements of the town. Among the first should be a good water supply. The question of providing the upper part of Woodford with water is one which has been under your consideration for years, and schemes have been submitted to you during the past year. It did not appear to him to be a matter which presented any very great engineering difficulty, though he felt sure that water would have to be brought from a lower level, and would require pumping. There was really plenty of water in the neighbourhood. He would urge this matter upon them as the most pressing in the district. It is not merely that there is a scarcity of good drinking water in Newtown, but in dry seasons there is hardly any water for domestic purposes, and in the event of a fire there would be absolutely no available supply.

Thornton—Dr. F. S. Rhodes, Medical Officer of Health for the urban district of Thornton, has issued his first annual report for the year 1900, from April to December 31st. When the last census was taken in 1891 the population of Thornton was 996, but the estimated population was now 3250—the increase being due to the erection of ammonia-soda works in the district, and the increasing popularity of Cleveleys as a holiday resort. The number of inhabited houses is 650, and the estimated population in the various parts of the district, which altogether comprises 3539 acres, is as follows:—Little Thornton, 270; Mid-Thornton, 1505; Burn Naze 930; and Cleveleys, 545. During the period covered by the report there were 69 births registered (37 boys and 32 girls), equal to a birth-rate of 29·92 per 1000. The number of deaths was 41 (17 males and 24 females), including three deaths of non-residents. The corrected number of deaths is therefore 38, equal to a death-rate of 16·48 per 1000. The death-rate of infants under one year was equal to 3·5 per 1000; whilst the seven principal zymotic diseases were responsible for seven deaths during the year. The water supply was principally from the Fylde Waterworks Company, but the district in many parts derived its supply from wells, and there were still some houses without any supply. Cowsheds which had been inspected were reported as lacking in

drainage, ventilaton, light, and cleanliness; and there were structural defects in some of them. The report concludes with several suggestions by which sanitary improvements could be made, the principal being the carrying out of the proposed sewerage scheme with as little delay as possible; the removal of ashes, refuse, &c., and the provision of hospital accommodation for the isolation of infectious diseases.

The first annual report of the Nuisance Inspector (Mr. H. Fenton) follows the Medical Officer's report, and deals chiefly with the number of notices served and other sanitary matters. The report states that 23 new houses have been erected and certified for habitation since Mr. Fenton was appointed in May last.

INSPECTION OF MEAT IN GLASGOW.

Mr. A. M. Trotter, veterinary surgeon to the Corporation, has just issued his annual report. During the year, he says, the work of this department has been much augmented. Hitherto meat inspection was under the dual control of the Chief Constable and the Sanitary Inspector, but at the end of the financial year it was placed under my supervision. At that time an assistant veterinary surgeon and seven Meat Inspectors were appointed. This number, however, was found to be inadequate if the work was to be carried out in a satisfactory and efficient manner, and it was therefore considered necessary to increase the staff by the addition of two assistant veterinary surgeons and six Meat Inspectors. The tuition of the staff has required constant and careful attention, but these and other difficulties have in a large measure been overcome. From the 1st June to the 31st December there were slaughtered —58,375 cattle, 1244 calves, 184,588 sheep, 31,882 pigs, 15 goats; of these 1368 cattle, 158 sheep, 524 pigs were partially or totally objected to.

The most important disease, considered from a hygienic as well as from an economic standpoint, is tuberculosis. Of the 23,587 home cattle—oxen, bulls, cows, heifers—dressed in Moore-street, Victoria, and Milton abattoirs, the serous membrane of the pleural or peritoneal cavities of 1035, or 4·38 per cent., were affected; 328, or 1·39 per cent., were partially, and 707, or 2·99 per cent., were totally destroyed as unfit for human food. Of the 31,882 home swine, 481, or 1·58 per cent., were affected; 46, or ·14 per cent., were totally, and 435, or 1·36 per cent., were partially objected to. The disease was found localised in the 435 swine in the lymphatic glands of the throat, and consequently the head only was destroyed. During the period 34,788 cattle arrived at Yorkhill, and an examination of the viscera after slaughter showed that 25, or ·07 per cent., were more or less affected. Of these three (·008 per cent.) were totally, and five (·014 per cent.) were partially destroyed, whilst in 17 (·048 per cent.) the internal organs only were objected to. Three cases of anthrax were discovered, and were reported in terms of the Diseases of Animals Act, 1894. The carcases of five cows were objected to on account of the internal organs being affected with cancer. This disease is comparatively common in Irish cows.

It occasionally occurs that large numbers of cattle are landed from the Irish boats in a dead or dying condition. An instance of this took place on the 11th November, when the carcases of twenty-two animals were brought to Moore-street slaughter-house to be disposed of. The amount of meat annually imported cannot be ascertained with any degree of accuracy. Meat is brought into the city by rail, by river, and by road. From 1st June to 31st December 2449 visits were made to stations. Of the meat examined, twenty-five consignments, of the aggregate weight of 4337 lb., were found to be unfit for human food. These included five carcases of beef, seventeen of veal, and one of pork. On inquiry it was ascertained that the consignments in two instances were *mala fide*, and consequently legal proceedings were instigated against the consigners.

During the period under review 632 visits were paid to the various wharves, with the result that four carcases of beef and five of pork were dealt with. The cause of seizure was tuberculosis and decomposition, and entailed the destruction of 1536 lb. 7153 butchers' shops were visited, and in 269 instances meat was seized and destroyed. These seizures comprised 1897 lb. of beef, 235 lb. veal, 350 lb. mutton, 57 lb. pork, and 144 lb. sundries—in all, 2683 lb. Legal proceedings were instituted in one case, when the accused was found guilty and fined £3 3s., with the alternative of fifteen days' imprisonment. 124 visits were made to sausage factories, but nothing of an objectionable nature was detected. The dead meat markets were visited several times a day and the meat consignments examined. The majority of the meat salesmen have cordially assisted the Inspectors by acquainting them of country consignments arriving between their visits. During the year 1220 visits were made to cowsheds, and 13,919 milch cows were examined. The milk of fifty cows was temporarily or permanently withdrawn from circulation; nine permanently on account of tuberculosis, and eight for various other diseases. During the past few years the standard of dairy stock has much improved, and at present compares favourably with those of other parts.

National Health Society.

OFFICIAL TRANSACTIONS.

Chester Branch.—The following report has reached us of the works of the Chester Branch of the National Health Society:—"Owing to the branch having to bear its own expenses this year it was thought wiser to have only a six weeks' course of lectures, and it is satisfactory to be able to say that the interest in the work has not only been maintained but deepened and enlarged. At Knutsford, where lectures on 'Hygiene' had been given the previous year to excellent audiences, there was another course on 'First Aid,' which was equally well attended. Lectures were given at Upton on 'Elementary Nursing' and awakened much interest, more lectures being hoped for next year. At Burton Point another and succeeding course of 'Elementary Nursing' was given in the village, and was well and regularly attended. Isolated lectures on 'Bacteria' were given at Saltney, Chester, and at Carnarvon, to large and appreciative audiences. At Carnarvon the Guild Hall had been taken, and Dr. Griffith was in the chair, while at Chester Dr. Stolterfoth presided. In Chester itself lectures were given on 'Advanced Nursing' and 'Hygiene.' General interest has been aroused in the work of the Society, and the untiring efforts of the hon. secretary, Miss Williams, have resulted in a thorough recognition of the value of tuition on all health subjects."

Training Lectures.—The special course of Training Lectures will be resumed on Monday, April 15th, when Dr. Kenwood will give the eighth lecture of his course on "Public Health," at 53, Berners-street, at 4 p.m. Dr. Squire will continue his series of lectures on "Human Anatomy and Physiology," on Tuesday, April 16th, at 2 p.m., when the subject of his lecture will be the "Glandular System." The other lectures next week will be held at the usual hours.

The annual statutory inspection of Greenock Waterworks by the water trustees and millowners was made on the 1st inst.

Sanitary Inspectors' Associations.

YORKSHIRE.

A CONSIDERABLE number of the members of the Yorkshire branch of the Sanitary Inspectors' Association met in Leeds on Saturday, the 30th ult., to discuss matters relating to their important work. They came from Halifax, Huddersfield, Batley, Middlesbrough, Harrogate, Pontefract, Tadcaster, Burley-in-Wharfedale, and other towns in the county, whilst the sanitary staff in Leeds was represented by Mr. Darley and several others. Seven of the Leeds Inspectors were proposed as members of the Association. Mr. E. E. Lawson, chairman of the Leeds Sanitary Committee, entertained them to luncheon, and, on behalf of the Corporation, gave the visitors a cordial welcome. Mr. T. Pridgin Teale, who has long lent his valuable aid to the branch as president, afterwards took the chair in the Civil Court at the Town Hall.

Mr. LAWSON made a few remarks on the important part which the Sanitary Inspector plays in safeguarding the health of the community. Noticing the presence of a lady Inspector, he remarked that there was a considerable sphere of usefulness in connection with sanitation for women. The infant mortality, more especially in summer, was excessive, and it was largely ascribed to improper feeding. In dispelling the ignorance which prevailed in relation to feeding young children, the lady Inspector might render invaluable service. In instituting inspection, there was no desire on the part of the sanitary authority to interfere with domestic arrangements, and the public would do well to welcome the Inspector, and afford facilities for making his efforts as effective as possible. In a city like Leeds, where the clothing industry was extensively carried on, and where there were so many out-workers engaged in it, thorough sanitation was obviously of the greatest importance. He urged the members of the Association to maintain a high standard of efficiency, to avail themselves of the County Council lectures relating to their work, and to be patient and courteous in the discharge of their duties.

Mr. C. W. EVINGTON (Hull), chairman of Council, spoke on the work of the Association. It was desirable, he said, that it should be as representative as possible, and this it was rapidly becoming. The membership was increasing by leaps and bounds, and a sub-committee was considering the question of arranging a conference of their Association with the National Association with a view to amalgamation. Their Association had now 800 members, one-seventh of whom belonged to the Yorkshire branch, which had now been established over five years.

Mr. G. DARLEY, superintendent of the Leeds Cleansing Department of the Corporation, read a paper on the work carried on under his supervision during last year. It contained some interesting details. The area of Leeds is 21,572 acres, and the total length of paved streets 212 miles. During the past ten years the loads of house refuse collected have increased from 129,085 to 173,408 per annum. The cost of collection has risen from £17,621 to £24,675, and the rate per load from 2s. 8¾d. to 2s. 10d. No less than 72,836 tons in 1900 were sent to the four destructors, the cost of destruction being 1s. 10d. per ton. One of the greatest difficulties is the disposal of the clinker, about 38 per cent. of the original weight of refuse, or 28,000 tons. To make this into mortar a sale of 90,000 tons a year would be required. To utilise it in the making of concrete flags an enormous plant would be needed, and, of course, a large demand for the product. A portion of the remainder of the refuse is sold as manure. The rest is taken to market gardens or tipped elsewhere. In street cleansing 240 workmen, 70 horses, 44 carts, and 26 sweeping machines are employed. The whole of the centre of the city is swept nightly, and the wood pavement more frequently when required. Every night eighty-seven miles of streets are swept. It is impossible to keep wood pavement clean without washing, and it must be continually shingled. A combined sweeping and collecting machine is in use, but in collecting the refuse it also takes up the shingle and sand. An improved machine would be a great boon. The sweepings last year amounted to 39,629 loads. No fewer than 14,539 loads were removed from street gullies. The cost of the paved street cleansing was £20,369. The paper also gave information regarding the flushing of house drains. Mr. Darley sees no difficulty in adopting steam motors in place of horse-power for street sweeping. They will do the work in less time, and be available for other operations.

In the discussion which followed, all were agreed as to the advantage from a sanitary point of view of street sewer and house drain flushing.

Alderman LUPTON remarked that in Leeds a case of infectious disease in a slum street was in a sense a boon to the inhabitants of it, for there followed immediately after the case was reported a thorough flushing of the drains and sewers, and for a fortnight afterwards the street was in a pleasanter condition than it had been before.

Referring to street cleansing, Mr. LAWSON stated that last year Leeds adopted a system of absolute washing in the Leylands, but they had to considerably modify it in consequence of the need to economise the water.

Dr. Cameron, Mr. Travis (Halifax), Mr. C. W. Evington (Hull), Mr. Joseph Lindley (Batley), and Mr. G. H. Anderson (Middlesbrough) also took part in the discussion.

Votes of thanks were accorded to the Leeds Corporation for the use of the Civil Court, to Mr. Lawson for his hospitality, to Mr. Darley for his paper, and to the chairman for presiding.

A NEW FORMIC FUMIGATOR.

IN addition to those described in our issue of March 28th, another novel appliance, recently introduced by the Sanitas Company, Limited, is the so-called "Formic Fumigator," and it also has been designed for disinfecting sick and infected rooms and hospital wards with formic aldehyde, the vapour of which disinfectant is generated in its most active state accompanied by the most plentiful supply of steam. It consists of a specially-prepared absorbent block, which is heavily impregnated with a chemical compound of such a character that when heated, formic aldehyde is generated in abundant quantity, and there is superimposed over the block a small tank or vessel from which water or "Formic Renovator" fluid drips through a wick upon the heated absorbent block at the same time, thus securing the generation of steam and supplementing the quantity of disinfectant vapour. The Formic Fumigator is made in two sizes, selling respectively at 3s. 6d. and 5s. each. Now that formaldehyde is regarded by many scientists as the best gaseous disinfectant, and considering that its vapours are not destructive to furniture and metal work, as are vapours of chlorine and sulphurous acid, it will be a matter of surprise if this fumigator does not come into general use.

It will be gathered from these observations that the Sanitas Company, Limited, by no means confine their manufactures to their better-known Sanitas disinfectants and appliances, but are up to date in all that concerns the subject of disinfection and disinfectants, and we can heartily recommend our readers to obtain a copy of their descriptive catalogue for their more perfect information.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

There are some municipal surveyors who can write official and annual reports which are pithy, readable, and valuable. There are, however, a greater number who are unable to do so. The reports of Mr. J. S. Pickering, the Engineer and Surveyor to the Nuneaton Urban District Council, belong to the former category, and his report recently issued for the year 1900 contains, as is usual with all his reports, much food for thought for surveyors generally.

Mr. Pickering appropriately refers to the detrimental practice of employing hired team labour, as to which I have previously referred in this column, which prevails with his Council—as it does with a large number of Councils—and very properly says that "the Council can scarcely realise the inconvenience of having each day to procure team labour from seven different contractors living in various parts of the district. It is impossible always to arrange each night for the number of horses which may be required the following day, as the weather may necessitate an entire alteration of work. Consequently, much time is frequently wasted in getting the team labour actually on the work, and the workmen cannot always fully employ their time until this arrives. The work would proceed much more smoothly and more economically with the bulk of the horses ready at hand at the Council's depôt, and especially when scavenging the roads has to be undertaken, and the horses are most needed, they cannot be obtained at all."

Mr. Pickering might well have added, as I have from time to time heard other surveyors urge, that labourers accompanying the horses are as a rule inefficient and underpaid men, and that they fail to carry out a day's work equal to that carried out by men directly employed by the Council. By a simple computation Mr. Pickering shows the area of roadway which can be scavenged in a working day and the number of loads of mud which can be swept and collected from a macadamised road in the same period, assuming one tip van to be able to remove seven cartloads per day.

It appears that the Nuneaton Council have determined to adopt the bacterial system for the treatment of the whole of the sewage of the district, and it is pertinent to the question that Mr. Pickering estimates that when the work which is now in progress has been completed, a saving of £1000 per annum will be effected. Such a sum appears to be very considerable for a town of the size of Nuneaton, but Mr. Pickering is not in the habit of making incorrect estimates; moreover, he has gained considerable experience in the working of the system, and during the past year by a partial adoption of it a saving of £386 has been effected over the old chemical system of treatment, so that the figures may be taken as absolutely reliable.

Mr. J. W. Bradley, the newly-elected Borough Engineer to the City of Westminster, has our heartiest congratulations on his appointment. The post is one of the "plums" of the municipal engineering profession, the commencing salary being £1000 per annum, rising to £1200 in four years. Moreover, Mr. Bradley has thoroughly earned his promotion by dint of ardent devotion to work and a close study of all matters appertaining to the engineering sides of municipal administration.

Mr. Bradley obtained his first municipal engineering appointment under the Burnley Corporation. From there he went to Leicester, serving six years under the Borough Engineer, and thence he was promoted to the borough engineership of Meson (Lancs), subsequently going to Wolverhampton, where he has been Borough Engineer for the past six years, succeeding Mr. R. E. Berrington, the former Engineer, who is now a member of the Corporation of which he was formerly an official. Mr. Bradley has the credit of having designed, executed, or completed works costing over £1,000,000, and yet in no case have his estimates been exceeded, or has it ever been necessary to require an additional loan to defray the cost of work in excess of that estimated for.

Although comparatively still a young man he has travelled considerably and taken full advantage of his opportunities, having been in the United States and Canada and most of the European countries, acquiring information on municipal and electrical engineering matters, and under such conditions any municipal engineer can beat the home-keeping man whose knowledge and experience are crippled with the conservative idea that England and everything English is, and must be, the best in creation—a foolish error which should have been exploded long ago. In the final selection for the appointment, Mr. T. de Courcy Meade, the Borough Engineer of Manchester, Mr. J. Paton, Borough Engineer of Plymouth, and Mr. Bradley, were the chosen three. Mr. de Courcy Meade, it was believed, had considerable chances, and very considerable influence was brought to bear in his favour, but it speaks volumes for Mr. Bradley's qualifications that he was eventually appointed by forty-five votes to five. Senex.

THE SANITARY INSPECTORS' EXAMINATION BOARD.

The next examination for Certificates of qualification for Appointment of Sanitary Inspector or Inspector of Nuisances, under Section 108 (2) (*d*) of the Public Health (London) Act, 1891, will be held in London on Tuesday, the 7th May, and the four following days. Particulars will be forwarded on application to the Hon. Secretary, Wm. R. E. Coles, 1, Adelaide-buildings, London Bridge, London, E.C.

PRESENTATION.

On Thursday evening, April the 4th, Dr. Monk (late Medical Officer of Health for Leicester) was the recipient of a handsome present from the Sanitary Inspectors, who desired to show their esteem and respect to their Medical Officer on his leaving for Kimberley, South Africa. Chief Inspector F. Braley made the presentation, which consisted of a group photo of the Inspectors, with Dr. Monk as centre figure, also a meerschaum pipe, cigar and cigarette holder, which was suitably inscribed. Mr. Braley, in making the presentation, said that they all regretted the doctor's leaving, for he had always worked in harmony with them as head of the staff; he therefore asked Dr. Monk to accept this small token of esteem and best wishes for success in his new sphere of labour. Dr. Monk, in reply, thanked the officers for their kindness in presenting him with such useful articles, which he should prize very much, and in using them and looking upon the faces of those with whom he had worked so well, he should remember that much of the success during his term of office was due to their willingness and efficiency in their work, and he should always feel it a pleasure to speak of the good feeling that existed between the Inspectors of Leicester and himself.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

THE CRUSADE AGAINST SMOKE.

THE annual report of the Coal Smoke Abatement Society is an admirable comment upon the excellent work performed by the same since its formation in March, 1899. Although the society at present only possesses one Inspector—a staff which we would remark is totally inadequate—no fewer than 2700 observations have been made on smoky chimneys in various parts of London. In 162 cases offences were proved and penalties inflicted, the fines so imposed amounting in the aggregate to the sum of £750. During the past year 1742 observations of offending shafts were reported to the Committee by this indefatigable officer, with the result that 1010 formal complaints were lodged, as the result of non-abatement, with the various Local Authorities concerned. As a result proceedings were taken in 125 cases, fines being inflicted to the amount of £494 13s. The salutary effect of this practical crusade against the smoke nuisance has naturally been very marked, and although we are still very far removed from the state of comparative perfection in this respect that we must work and legislate for, there is no denying that the nuisance is much less acute than formerly. The evils associated with the nuisance are so pronounced, and have been so often commented upon in these columns, that there is no need for reiteration; but the following two facts, instanced by Sir William Richmond, the president of the society, in the April number of the *Pall Mall Magazine*, may be cited as going to prove the need that exists for further determined action. The smoke cloud of London, Sir William tells us, is plainly discernible at Lockinge, sixty-four miles away, and in its passage overhead leaves a distinct residuum of black upon the soil. Again, in London itself, in the form of unconsumed fuel, a black cloud representing upwards of 6000 tons of coal, is in suspension every day. This wanton waste of fuel is in itself sufficiently serious to call for remedial measures, even apart from the great question of health, in which we are necessarily chiefly concerned. Harking back to the report, we find that the convictions previously referred to have had a salutary effect upon the various owners of trade furnaces, and, having thus learned that it is not within their province to allow their chimneys to belch forth black smoke to poison the atmosphere with impunity, they have in many cases taken steps to abate the nuisance. A good deal of ignorance, however, still exists as to the measures which ought to be taken to this end—ignorance which a perusal of a little threepenny booklet on "Smoke Prevention," by Mr. William Nicholson, Smoke Inspector, Sheffield, published at the office of this journal, would do much to dispel. There is still an idea that the excuse of not being able to procure Welsh coal will hold water, and those who advance it seem quite oblivious of the fact that in the section of the Public Health Act referring to smoke Welsh coal is not even mentioned. The only cure for this kind of ignorance lies in the imposition of still heavier fines, and when this is done the offenders will perhaps think it cheaper in the long run to take such measures as are at hand for the suppression of smoke than to pay their quota into the magisterial exchequer. In a former article on the subject we cited the instance of Nottingham, where the emission of black smoke is now practically unknown. The canny folk of the lace-making centre, when they discovered that the black smoke was playing havoc with their goods, soon set to work to find a remedy; and what

Nottingham can do can surely be done by London. In the meantime we consider the metropolis is under a great obligation to the Coal Smoke Abatement Society and to Sir William Richmond in particular, for their efforts to minimise a nuisance which is so injurious to the health of the community, and we venture to hope that the public appreciation of their efforts may take a tangible shape. Such a society should certainly not be allowed to languish for lack of funds to carry on its work.

A Prussian Rescript.

A FEW months ago we published some interesting details of proposed efforts to deal with the housing problem in Berlin. Since then the Prussian Ministry appears to have given special attention to the matter, with the result that there has just been issued a special rescript to the civil governors of all the provinces on Monday. The Berlin correspondent of the *Daily News* sent over a summary of this document, from which we learn that the Government starts from the principle that in the first line Municipal and District Councils are called upon to take the initiative in this matter, and only in cases where their measures prove inadequate must the State interfere. It is pointed out in the rescript that Municipal and District Councils have the moral obligation to provide all people in their employ with cheap and healthy dwellings, and to promote all endeavours to extend this benefit to the poorer classes in general. For this purpose the Councils can either themselves create building companies or support them. The preliminary condition, however, is that all these companies shall build small and cheap dwellings. It may be pointed out that this is only the extension of what is largely done by private firms in Germany. In most large concerns the workers are housed by the employers. The Government then proceeds to point out how the Councils might best carry out their task. They are to give financial assistance to building companies, either by subscribing for a considerable number of shares, or by loan at a moderate rate of interest, or, further, by the complete or partial abrogation of the dues for the making of streets and laying of sewers. But this payment must be made later on if the buildings are given up to other purposes. The building companies to which these facilities are to be granted must not pay a higher dividend per year than 4 per cent., the surplus being used for further investments. In case of the dissolution of the company the shareholders have only a claim for the nominal value of their shares. The Municipal and District Councils are further, if necessary, to give financial help by lending money on mortgage. Should the towns not have the money themselves, they may raise loans from the savings banks, or from the Imperial insurance offices, which have an enormous capital accumulated from the contributions to the old age, invalidity, and accident insurance at their disposal. This has to be done in such a way that the Municipal or District Councils are the debtors of the insurance office or savings bank, and the creditors of the building company to which they lend the money at a rate of interest of a quarter of one per cent. higher than they have to pay themselves. If circumstances let it appear expedient, the Municipal Councils can stand bail for the companies which borrow the money.

Help for the Contractor.

BUT it is contemplated that help may be given to individuals as well as companies; and the rescript goes on to state that the municipality shall grant such requests, but, of course, this can only be done on condition that the Municipal Councils have a guarantee in hand that the buildings will afterwards not be used for other purposes. In such case the Councils have the right of pre-emption at a nominal price. The Municipal Authorities, the Ministerial decree says, ought also to create adequate and cheap means of communication, so that the working population and the school children may be able without much loss of time to live outside the town. The building companies are also to have the advice of the building experts employed by the State and town free of charge, and they have not to pay the different taxes which, as a rule, are levied on the building of houses. As the present evils are chiefly due to unhealthy speculation in building land, the Ministerial decree suggests that the towns ought to buy up as much land in the neighbourhood as they can, in order to prevent it passing into the hands of speculators. The towns are then to sell the land or houses in their possession with small profit and on convenient terms to contractors who undertake to build cheap dwellings. The Ministerial decree finally points out that only by a co-operation of all factors concerned in the matter—State, towns, and employers—can a satisfactory solution of this most difficult problem be expected. It further suggests the creation of a central office in each province and the foundation of associations in single districts to be in permanent communication with the central office. Of course many of the proposals are peculiar to German methods of government, but they show that a decided effort is being made to grasp the difficulties of a pressing problem, and our own Government might do something in the same direction.

A Singular Difference between Experts.

THE well-known proverb of "doctors differing" received one of its most remarkable illustrations that we have seen for a long time in a diseased meat prosecution in Edinburgh, which was brought to a close last week. From first to last, between the first leading of evidence and judgment, the case was spread over several weeks. The charge related to two sirloins of beef, which had been sent to market for the purpose of sale, and intended for human consumption, and which were diseased, unsound, and unfit for food. Additional interest was imparted to the case from the fact that the meat was passed by the Glasgow dead meat Inspectors, although seized in Edinburgh,

and from the eminence of the experts called on both sides. For the prosecution, it was stated by a veterinary surgeon and Assistant Inspector of Markets that he had found the pleura and the peritoneum stripped to a large extent, for the purpose apparently of removing the tubercular deposits, of which, notwithstanding, there were traces. The meat was quite unfit for food. The evidence of several other Meat Inspectors was to the same effect. Dr. Shennon, Lecturer on Pathology, Edinburgh, said that he had found, on a microscopical examination, organisms which he thought undoubtedly tubercle bacilli. This evidence was corroborated by Professor Dewar, who also considered that the peritoneum had been stripped in order to hide something; by Principal Williams, of the New Veterinary College; and by Dr. Williamson, Chief Sanitary Inspector for the city. Dr. Williamson referred, further, to the instructions of the Local Government Board, that where the pleura are stripped the carcase must be seized. For the defence, experts of equal eminence gave it as their opinion that the meat was perfectly healthy. They included Professor Mins, Professor of Pathology in Glasgow University, and Dr. Welsh, Pathologist to Edinburgh Royal Infirmary, who both, while admitting the presence of organisms in the meat, were quite clear that they were not tubercle bacilli. The most singular evidence, however, was that of Mr. Trotter, Chief Veterinary Surgeon to the Corporation of Glasgow, who said that over 50,000 cattle were killed in Glasgow every half-year, and the meat inspection was carried out on the Belgian system, trained men being employed to examine the various portions of the animal. So strict were their examinations in Glasgow, that they were universally accepted, and he had never known of meat despatched from Glasgow being challenged. Mr. Trotter, however, went further. On hearing of the seizure of meat which had passed the Glasgow Inspectors, he went to Edinburgh and examined the sirloins. He found no evidence of tubercular nodules, or disease of any kind, but the surroundings, he said, were very dirty, and the table on which the meat was lying was so dirty that any organisms might have been on it. This was in the Edinburgh Sanatorium, and he declared emphatically that if he had kept his chamber in such a condition, he was afraid he would be reported to the Sanitary Inspector for having a nuisance. It was a serious charge to make. We wonder what the Edinburgh Sanitary Authorities will have to say in reply. The above is a bare *résumé* of the evidence, which was too voluminous to report fully. Seldom has a case arisen in which the evidence has been more conflicting, or in which the experts were more diametrically opposed. In his judgment, however, the Sheriff held that the evidence for the defence failed to shake that for the prosecution on the question of the presence of tubercle bacilli, which he considered to have been proved. At the same time he found the respondent to have established "that he did not know, and could not with reasonable care have known," the condition of the meat, and that he was entitled to a verdict of that nature. It may be mentioned that at the hearing of counsel, the Sheriff asked the counsel for the defence whether he would be satisfied with such a finding, but the latter maintained that the evidence he had led showed that the prosecution had been unjustifiable, and he pressed for an absolute acquittal.

The Early Closing of Shops.

When Lord Avebury moved for the appointment of the Select Committee which is now, under his chairmanship, considering the question of the early closing of shops, Lord Salisbury indicated that his chief objection was that it would unnecessarily curtail the convenience of the shopping public, especially among the poorer classes, and he hoped that the evidence to be laid before the Committee would adequately represent that large and usually voiceless class. Since then it has been noteworthy, not only at the sittings of the Committee, but in trade gatherings in various cities, that the feeling of the working classes, so far as it can be voiced by trade unions and similar organisations, is entirely in favour of a restriction of the present excessive hours in shops. The working classes as a whole are too sensible themselves of the blessings of liberty not to feel sympathy with the complaint of shop assistants that their long evening hours are both detrimental to health and deprive them of all opportunities for social intercourse, educational improvement, or recreation. Working men are perfectly ready to recognise that late shopping is due more to lack of consideration than necessity, and that earlier closing would not put them to any serious inconvenience. But even were it otherwise, is the inconvenience to which some people may be put to be weighed in the balance against the physical and social harm that shopkeepers and their assistants suffer on account of having to keep their shops open, under the stress of competition, to inordinately late hours? There surely can be only one answer to such a question.

The Responsibility of Public Analysts.

The certificate of a Public Analyst may be made the foundation of a criminal charge, and therefore it is all the more incumbent on him to exercise the greatest caution in every analysis, and in stating the results. But it would be most unfortunate, on grounds of public policy, if the possibility of error were to render him liable to a civil action of damages. This has been laid down by Sheriff Robertson, of Aberdeen, in a case of mistaken analysis which came recently before him. It arose out of a prosecution, under the Food and Drugs Acts, of an aërated water manufacturer, in respect of certain lemonade, which Mr. Thomas Jamieson, Public Analyst for the city of Aberdeen, certified to contain traces of lead. The sample was, at the request of the defendant, sent to Somerset House to be analysed, and the Government chemists reported that they had found a trace of copper, but not of lead. This,

of course, necessitated the withdrawal of the complaint; and the manufacturer, feeling aggrieved at the proceedings, and their publication in the newspapers, raised an action against Mr. Jamieson for £1000 damages. The Sheriff, however, has dismissed the action, remarking that the Analyst holds an impersonal position. Samples are sent to him for analysis, but he does not know whence they come. It is his duty to make his analysis to the best of his judgment, and send a certificate of the result to the Sanitary Inspector. There his duty ends. It is then for the Sanitary Inspector and his legal advisers to consider the advisability of a prosecution, which they bring if they think the facts will warrant it. The bringing of the prosecution, which was the thing that caused the damage complained of, did not rest with the Analyst, but with the Sanitary Authority and their advisers. In such circumstances, to hold that a public official who makes an analysis can be called on to answer a claim of damages without averring malice on his part, was quite unreasonable. In this connection we may remark that too great emphasis cannot be laid on the importance not merely of absolute accuracy in the analysis itself, but also of the correct statement of the result in the certificate, in which the most scrupulous care should be taken to adhere strictly to the statutory requirements. We have known several cases recently in which prosecutions have proved abortive on account of deviations in the mode of framing certificates from the statutory form, which might appear trivial to the Analyst himself, but are not so regarded by the judge. In proceedings under the Food and Drugs Acts, which are quasi-criminal, the very strictest construction is placed on the Analyst's certificate; and it is a most unpleasant position for a Local Authority to be placed in to be thrown out of Court on account of a technical informality.

Juvenile Smoking.

Among various matters referred to in the annual report of Dr. G. H. Butler, the Medical Officer of Health for Wealdstone, for the year 1900, is the growing evil of smoking among juveniles. He alludes to it on the ground that it is bound to have an influence for evil on the health of many individuals if allowed to proceed unchecked. It was quite a common thing to see young boys and lads smoking openly in the public streets. The sight in itself was objectionable, but became positively sad and painful when one considered the evil effects which indulgence in this habit by the young was sure to bring about. It caused premature undermining of youthful constitutions, and destroyed that healthy physical condition which was essential to the growth and development of a fine and strong race. Boys and youths who indulged in this habit could not expect to develop into men with nerves and muscles strong and fit to do their duty manfully in the battle of life—worthy sons of the Empire. It became a serious question whether legislative measures ought not to be passed to prohibit smoking among, and the supply of tobacco to, boys under sixteen years of age. At present no legal check or restriction whatever existed. No doubt the habit was generally contracted in ignorance of its baneful effects, and good might be done, the Doctor thought, if schoolmasters would make these known amongst boys under their charge.

Lady Sanitary Inspector for Middlesbrough.

As the result of the recent report of Dr. Dingle, Medical Officer of Health for Middlesbrough, upon the great percentage of infantile mortality in the borough, the Sanitary Committee have decided upon the appointment of a Lady Sanitary Inspector. We are glad to note that this decision has been approved by the Town Council. There is no doubt that much good will arise from the appointment of a Lady Sanitary Inspector, especially in the matter of instruction in the rearing of children. Her duties will be to undertake a house-to-house inspection in the poorest parts of the town, call attention where necessary to the importance of cleanliness, advise as to the rearing of children, the nursing of the sick, and the prevention of diseases. Most of the large towns have such lady officers, and their work amongst the poorer classes has been most successful, and such as to justify the Middlesbrough Corporation in making the appointment.

CORRESPONDENCE.

(*To the Editor of* The Sanitary Record.)

We do not in any way hold ourselves responsible for opinions expressed by our correspondents.)

THE HOUSING OF THE WORKING CLASSES.

Sir,—The housing of the working classes is a question which illustrates the need of method and concentration in social reform to which I recently referred in your columns. We require systematic treatment of the facts, the law, and the administration of the law.

First as to the facts in London and the country. If we could obtain systematic information as to the evils which exist, no doubt in many cases reform would follow at once by the action of public opinion. Only last year it was discovered that some of the worst property in London was owned by the Lord Lieutenant of one of the Midland counties, and some by a curate of a London church. The registration and publication of the names of the owners and occupiers of insanitary property would be the first step. What is true of London is even more true of the country. The owners have in many cases no idea of the condition of their cottages. The newspapers are sometimes taken to task for sensational statements about housing, but could any statements be stronger than those of the late Mr. William Little and Mr. Wilson Fox (now editor of the *Labour Gazette*), after a careful official inquiry in the rural districts? Mr. Little said that "a large proportion of the cottages are below a proper standard of decency and comfort; many of them are vile and deplorably wretched dwellings." Mr. Wilson Fox stated that "many houses are more fitted for animals to inhabit than men and women, and in which no human being could be either happy or contented." These two gentlemen, whose inquiries are borne out by subsequent writers, down to the present year recommended as a remedy that the owners of all houses let at a rental of

less than £10 a year should make a return to the Sanitary Authority every year stating the number of persons in each cottage, their sex and age, whether the house is provided with a proper water supply and sanitary accommodation, and whether the premises are in good repair. I moved for such a return in the last Parliament; but the Government refused it, and I think they incur a heavy responsibility if they take no further steps in the matter after refusing to carry out the principal recommendation made by two such experienced and practical men as Mr. William Little and Mr. Wilson Fox as the result of an exhaustive inquiry.

But, turning from the facts to the law, the next question is that of codification. The Housing of the Working Classes Act of 1890, and the London Public Health Act of 1891 were a great step towards consolidation; but the question now is whether it would not be possible to consolidate the whole of the laws relating to the public health; for the Housing of the Working Classes Acts are only a chapter, though a very large and important chapter, of that legislation. Whether this is possible or not, it is most desirable that an authoritative digest of the law on housing, of which there has been some talk, should be published by the Local Government Board, and also an abstract, like the abstracts of the Factory Acts, which could be not only circulated to the Local Authorities, but posted up in insanitary districts when necessary. After the law come the administration and the control of the administration. The administration of the Housing Acts is in the hands of the Local Authorities, who have been very supine in the past, and act largely through medical officers, who have no fixity of tenure of their offices and are for the most part miserably paid. Six hundred and eighty-four, or more than one-third, of these officers receive £30 a year and under, eighty-four of them receive £20 and under, no less than fifty receive £10 and under. Public opinion would have to be directed to remedy this scandal systematically. A man who receives £3 a year, as in one case, cannot be expected to carry out such important and invidious work adequately. But when all is done that can be done by the Local Authorities, it seems that some central supervision may be found necessary. There is no doubt that surprise visits by travelling Inspectors would do a great deal to awaken local interest. These would be appointed by the Local Government Board and by the Home-office, but we may hope some day to see all the Acts relating to the public health under one central department.

After the question of administrative control by a superior department comes the question of judicial control by the Courts and legislative control by Parliament. Under the first head arise questions like conflicts between authorities. These drag on from year to year from want of a proper system of administrative justice. The uncertainty which exists in matters often of life and death, and the delays incidental to decisions in the ordinary course of justice, lead one to ask whether the time has not come to add an extra Judge to the High Court to deal with such business. In the long run we shall no doubt have to face not only the problem of a careful delimitation of the spheres of action of local authorities, but also the very important question whether, having in 1834 adopted the foreign system of paid professional officials for administrative work, we can much longer defer the organisation of a proper system of administrative justice.

After judicial control comes the control of Parliament. Here it is not generally known that Parliament has so successfully decentralised the question of housing that, except on the narrow question of audit, the problem of housing cannot be raised on the Speaker leaving the chair when the House goes into Committee on Civil Service Estimates or on the Civil Service Estimates themselves. In view of the ever-increasing obstacles placed in the way of the action of private members in moving resolutions or introducing Bills, practically their only method of exercising control is the unsatisfactory one of questions. This seems to me a fact to which attention should be drawn; the remedy for the evil can only be applied by members of Parliament, and I have already trespassed too much on your space to make any suggestions in the matter.—I am, yours faithfully, GEOFFREY DRAGE.

THE UTILISATION OF SEWAGE.

A PAPER on this subject was recently read at a general meeting of the Institution of Civil Engineers, Dublin, by Mr. Marmaduke F. Purcell. The meeting was held in the rooms of the Institution, 35, Dawson-street, the President, Mr. Edward Glover, presiding. There was a large attendance of members.

Mr. PURCELL, in the course of his paper, said: The problem besetting every engineer dealing with sewage drainage is how, when he has collected the sewage, he is going to get rid of the solids contained therein. This is comparatively an easy matter in the case of small towns situated on the seashore, but becomes more perplexing in accordance with the increased size of the town or city which has to be dealt with, as in the case of large deposits being sent out with the tide, there is always the danger, almost the certainty, of such deposits being swept back to a large extent, and re-deposited on the foreshore, there to become a nuisance and a danger, to say nothing of being a waste of valuable material. Then, as we go further inland the problem becomes more pressing, for you must either pollute your rivers, again losing matter of value, or you must treat it as a manure, and sell the sludge or cake to the farmers, or else utilise it on sewage farms. Both these latter alternatives have their respective values, and also their striking disadvantages. The question of sewage farms is one which I do not feel myself competent to enter into, but I understand that to be effective the area must be great, so as to get the acme of efficiency, and the sludge should be dug in, and the ground left fallow for three years to obtain the best results; consequently, in any up-to-date sewage farm, you could only have one-third of it under cultivation in any one period; but there is a much graver aspect of the sewage-farm system, and that is the indestructibility of disease germs by the ordinary methods of precipitation employed at depositing stations, and the absorption of such germs into the cellular tissues of the vegetables grown on such farms, and their transference in the course of their use to the human body, and the resultant spread of such diseases as typhoid, &c. This alone should lead us to do all we could to utilise in some other way the valuable asset that every community produces, which many throw away, others misapply, and all would like to recover. But the question is how to do this efficiently and economically; how to produce value where at present we have loss and danger. These were the questions that presented themselves to my mind some years ago, and to which I endeavoured to get a satisfactory answer. I knew that many workers before me had gone into the same field and retired baffled and disheartened. In the course of my investigations I came to the conclusion that in place of looking for and dealing with a single resultant of the quartette that may be derived from the sludge deposit, the only thing for an economical working would be to obtain all four (main) products, and that, if possible, at a single operation. My object is the distillation of the filter-pressed sewage obtained from any sewage disposal works where the use of filter presses is adopted, and

assuming the cakes of sewage can be obtained first hand, and in such a condition as to bear transit, then the process has for its ultimate object the production of oil, ammonia (as ammonia water), and a solid residue which is to be converted into cement—for which purpose it is admirably fitted, especially where lime has been used as a precipitant in the separation of the sewage into sludge and effluent, as is the case in London. The paper then gave the results of an analysis of the London sludge, and went on to state that it was found that by simply drying the sludge it would give a body capable on distillation of yielding very large amounts of ammonia, and also an oil which would be of value as a carburetting material in the manufacture of gas. It is evident that if the compressed sewage can be obtained from the sewage works for the simple cost of transit, or at a nominal cost, or utilised by the Authorities on the spot, and that by distillation it can be made to yield a high percentage of ammonia, and also give oil, and a valuable residue in the form of cement, then a very valuable return will be made by treating such material.

Mr. James Dillon said Dublin was spending enormous sums in completing a main drainage system, and there was every hope that in bringing down the sewage to the Pigeon House the scheme would be fairly successful. But when they had got the sewage to the Pigeon House it would be necessary to have extensive works to enable the sludge to be collected and filled into ships of a peculiar kind at all seasons of the year, and he was afraid there would be some difficulty experienced in taking it out to sea in stormy and severe weather. If Mr. Purcell's system turned out to be successful an enormous sum would be saved in the cost of ships, because all that it would be necessary to do would be to construct works such as Mr. Purcell had indicated in his paper. He hoped the Corporation would give the method recommended in the paper an honest and fair trial, with the object of cutting down the cost of dealing with the sewage in the way originally intended.

After a few observations from Mr. Dick,

Sir Charles Cameron said the subject dealt with in the paper was a very important one, quite apart from the particular scheme for disposing of sludge which the paper brought before them. It was a matter of great importance to be able to deal economically with the immense quantity of semi-solid matter which had to be dealt with in the case of a large city like Dublin. There was no doubt that when the sludge produced was conveyed out to sea, there was no return of any value whatever for the labour bestowed upon the disposal of it. The country was not enriched by the production of any one article. There was no material for the making of cement, and no material for manuring their fields. If by treating the sludge differently they could get out of it something of value that would be a gain to the country at large, because they would have something to put on their fields and use it in their industries. He thought that was the idea that ran through Mr. Purcell's paper, that they ought to do something with the sludge, even if in treating it in the way he indicated it would be necessary to spend a larger sum per ton than it would cost to send it out to sea, for the simple reason that they would obtain something in return for the expenditure. He was quite satisfied if in Dublin they could send a clear liquid out to the sea, no matter how much dissolved organic matter it might contain, for they were never likely to see any solid matter from it. That, however, did not affect Mr. Purcell's theory. It would, in his (Sir Charles Cameron's) opinion be much easier to treat the sewage of Dublin as that of a town upon the sea than as that of an inland town. But, in any case, whether a town was on the sea or inland, there would be a large quantity of matter precipitated. He thought there was a great deal in the paper as regards the proper way to treat sludge. In Dublin some thought they ought to carry it out to sea. Another proposal was that the sludge, when sufficiently compressed, should be used to reclaim the foreshore along the Pigeon House Wall. The foreshore there was certainly anything but salubrious; it was most offensive very often. There was an idea that this compressed sludge might be used to reclaim a portion of the foreshore along the southern side of the Pigeon House Wall. He thought there was a good deal in Mr. Purcell's paper, though he was not quite prepared to say that all his calculations would come out in actual practice. It would, in his opinion, be well worth while to give a trial to the process brought before them in the paper. It was not necessary that any great expenditure should be incurred in doing so. The process was so comparatively inexpensive that in the case of Dublin he believed it would be well worth while to give it a trial, and see what were the products per ton that could be obtained from it, and whether it would be cheaper than the system of carrying the sludge out to sea.

Other speakers addressed the meeting.

Public Works.

SEWERAGE.

The Darfield Urban District Council is obtaining a loan of £9856 for the sewage scheme.

Further works of sewerage, estimated to cost some £20,000, are to be carried out in the urban district of Gorton.

Sanction has been obtained by the Heaton Norris Council to borrow £5720 for purposes of sewerage and sewage disposal.

The Leek Rural District Council has called in Mr. J. E. Willcox, C.E., of Birmingham, to advise it with respect to the sewage disposal of the district of Endon.

A Local Government Board inquiry has been held at Tring with reference to an application by the Urban Council for sanction to borrow £5500 for works of sewerage and sewage disposal.

The Broadstairs and St. Peters Urban District Council have decided to borrow £10,000 for works of sewerage, the enlargement of the Council offices, paving of streets, and the laying out of a pleasure ground.

The Clerk to the Rural District Council of Crickhowell has been instructed to write the Local Government Board urging it to hold an inquiry in connection with the Llangattock water and sewerage scheme as early as possible.

The Boston Town Council has instructed its Surveyor to prepare a report as to a pumping scheme for the drainage of a portion of the west side of the town, and to submit an estimate for a destructor. It has been decided to purchase disinfecting apparatus at a cost not exceeding £100.

A special meeting of Morpeth Town Council was held last week to further consider the question of the sewage disposal scheme. The Town Clerk (Mr. F. Brumell) brought up a report from a Committee of the whole Council, which stated that the whole position had been re-considered, with the advice of Mr. Balfour, jun., of Messrs. D. Balfour and Son, engineers, Newcastle. The report having been read, the Council resolved that in view of the plans amended by Messrs. Balfour in accordance with the suggestions of the Local Government Board, the Council would proceed with the whole works proposed, and apply to the Local Government Board for a loan to enable it to do so, including the pumping of the sewage and dry-weather flow on to the irrigation ground on the Parish Haugh.

Colonel Dunford, R.E., held a Local Government Board inquiry at New Mill, near Holmfirth, recently, into the application of the New Mill District Council for sanction to borrow £12,550 for a scheme of sewerage and sewage disposal. Mr. Sam Shaw, C.E., of Dewsbury (the Council's engineer), and the Chairman and Clerk gave evidence.

The London County Council has agreed, on the recommendation of the Local Government and Taxation Committee, that it be empowered to take all necessary steps for the protection of the Council's interests in connection with the hearing before the Privy Council of the petition of the Friern Barnet Urban District Council against the Hornsey drainage scheme.

At a recent meeting of the Works Committee of Dundee Town Council, the drainage of the outlying portions on the north side of the city was discussed. A plan showing the proposed main sewer was submitted, together with the notice thereof. The Committee approved of the plans and sections, and authorised the same to be executed. The cost is estimated at £2800, but under agreement with Sir Reginald Ogilvy, Bart., and Mr. Erskine, of Linlathen, these two proprietors make contributions to the expenditure for ten years equal to about £40 per annum, while owners and occupiers outside the burgh, representing 60 per cent. of the extent of the sewer, would have to pay a rate of 6d. per £1.

The Edinburgh Burgh Engineer has prepared a report on the Craigentinny Meadows irrigation scheme, in which he recommends that irrigation should be continued in the Meadowbank district, and that a 7ft. 6in. culvert should be made from Craigentinny Meadows to Piershill Station, and a 7ft. culvert from there to London-road to carry off the drainage. The normal flow in the sewer is about 800 cubic feet, but in spates the flood waters and the sewage together amount to about 18,000 cubic feet or thereby. The length of the culvert required from its present termination to Craigentinny Meadows—that is to say, the length of the open burn requiring at once to be covered in—is 1200 yards or thereby, and would cost, irrespective of way-leave, £10,000 or thereby. Mr. Cooper thinks that irrigation might for the present be continued at Craigentinny Meadows.

Last week at a meeting of the Ribble Joint Committee at Preston, Alderman Burrows said that Burnley had spent a tremendous amount of money in endeavouring to improve their effluent. In trying to meet the wishes of that Committee they had incurred a rate of 9½d. for a town of about 10,000 inhabitants. The Local Government Board required them to have so much land for filtration purposes, but they had found that by putting down bacterial beds, or filters, they were able to deal more effectually with the sewage, and that the effluent was of a purer character than when it went over the land, which became choked. Dr. Ferguson informed the Committee that the Corporation of Burnley had already bought 63 acres of land, which had cost, with drainage, £400 per acre, and they had found that an acre would only take 8000 gallons of effluent. Their daily outfall was two million gallons, and this meant a much greater outlay than they had even made already. By the bacteriological system they found that one acre would deal with 250,000 gallons, which meant that eight acres would be sufficient to cope with their daily flow of sewage, and be a saving of money and labour. He moved "that a report be made to the Local Government Board that the work of the Local Authorities dealing with their sewage effluents, where their present works are insufficient, to prevent serious pollution of the rivers under the control of that Joint Committee, will be much facilitated if the Local Authorities are allowed to borrow capital for works of purification of sewage by bacterial means, unaccompanied by any stipulation requiring the acquisition of land for further filtration in cases where they are prepared to take their chance of the works proving efficient." The report was adopted unanimously.

WATER.

The Tees Valley Water Board has approved the issue of precepts to the amount of £24,000 upon the Corporations in the following proportions:—£12,000 on Middlesbrough, £10,000 on Stockton, and £2000 on Thornaby.

The Local Government Board has sanctioned the borrowing by the Keighley District Council of £1000 for the purchase of the Redcar and Whitefield waters, and the laying of pipes, but only on condition that a certain length of pipes be laid under the road should be of iron and not of pot.

The contract for the Bewdley water supply has been secured by Mr. W. H. Reading, contractor, of Molineux-street, Wolverhampton. The contract amounts to nearly £11,000. Mr. R. E. W. Berrington, of Wolverhampton, is the engineer of the scheme, which is to supply the whole of Bewdley with water to be obtained from a well and then pumped into a reservoir.

At the last monthly meeting of the Oystermouth Local Board a report of a Committee was adopted which stated that, after carefully considering the analyses of water made by the county laboratory and a letter from the Local Government Board, the Committee recommended that the questions of the company's responsibilities as to supply and purity be tested under the Public Health and Waterworks Clauses Acts.

We understand that there is unbounded satisfaction at Workington that the Corporation has at last cast aside its supineness in regard to the water supply, and has resolved to carry out the scheme for the laying of a second pipe from the lake, whereby the people will have a permanent supply of water. The scraping of the main from the lake to Workington is not yet completed, but on all hands the verdict is that it will not meet the needs of the town and district. The new works are now making rapid progress, the contract for the supply of pipes will shortly be placed, and it is calculated that the entire scheme will be completed in eighteen months.

At the last meeting of the retiring District Council a letter was read from the Local Government Board with regard to the proposed water supply for the parishes of Bridgwater Without, North Petherton, Huntspill, Chedzoy, Puriton, and Bawdrip. The Board asked for particulars as to the scheme, estimated to cost £30,000, and also for the proportionment to be made of the cost on the various parishes included. It was decided to hold a special meeting a month hence to consider the question of apportionment, and in the meantime to inquire from the Local Government Board what was the course usually adopted. The estimate was presented and passed, showing a slight increase over the past half year.

The Gas and Water Committee of the Birkenhead Corporation is recommending the Council to accept the offer of Messrs. R. F. Craig and Co., Limited, Paisley, to supply, erect, and fit up complete, at the Ford Waterworks, two sets of air-lift apparatus and pumps, capable of raising 16,000,000 gallons per week from a depth of 780ft. in the borehole, and delivering the same into the tank on the water tower at Flaybrick Hill. It is urged that, as the question of the water supply to the borough is of pressing importance, the contract should be entered into without delay, in order that the supply of water at Ford Waterworks may be utilised to a fuller extent than has hitherto been possible, and to meet the increasing consumption of water in the area supplied by the Corporation.

Dr. Best recently gave an instructive address at the Liberal Club on the question of the purchase of the Louth Waterworks by the Corporation. His argument was that the present worth of the waterworks undertaking was about £9000, and yet the Highways Committee of the Corporation had unanimously recommended its purchase at £15,000, and this recommendation had only been defeated in the Council by a majority of one. He showed that at the present time only one-third of the people of Louth were using the water, and he argued that it would be quite unfair and most unjust for the other two-thirds to be compelled to pay their share of the cost for the benefit of the other third. He also showed that the income of the company was ridiculously small, and that its £10 shares in the open market realised under £5. The original cost of the undertaking was about £20,000.

After repeated and vexatious delays, the scheme for bringing in an improved supply of water for East Looe is now practically settled, and will be proceeded with at once. At a special meeting of Looe Urban Council last week, convened for the purpose of determining the method of proceeding with the work, Messrs. S. W. Jenkin and Son, of Liskeard, the engineers, reported that they believed all the conditions and requirements of riparian and other owners had been at length satisfactorily settled. After discussion, it was resolved that the Council itself purchase the pipes and valves, and the Clerk was instructed to obtain tenders from firms approved by the engineers, and that tenders for laying the mains and constructing the reservoir be invited as soon as possible. The new works for the West Looe supply are now approaching completion, and the works now to be proceeded with will form the second section of a comprehensive scheme interchangeably available for both places.

In view of the proposed purchase of the Louth Waterworks undertaking by the Corporation, it is interesting to find, says the *Lincoln Mercury*, that so early as 1854 the question of public water supply led to the passing of an Act of Parliament (17th Vict., cap. 51). The promoters appear to have seen Messrs. Samuel Trought, John Hurst, Thos. Young, Cornelius Parker, John Booth Sharpley, Archibald Dymock, William Henry Adams, and Herbert Ingram. The Act known as "The Louth Waterworks Act, 1854," provided for the incorporation of a company for supplying water within the parishes of Louth, Hallington, South Elkington, Louth Park, and Keddington. The capital was to be £12,000, in 480 shares of £25 each; and there were to be nine directors, namely, the eight above named and Mr. Henry Munt. The Act does not state what sources of supply the company were to have access to. As the undertaking does not appear to have become established, it would be interesting to learn why it fell through. The present company's Act is dated 1871.

LIGHTING.

The London County Council has agreed to lend the Stepney Borough Council £10,000 for electric light installation.

A Local Government Board Inquiry was held at Southend last week with reference to the Town Council's application for sanction to borrow £40,030 for the purposes of electric lighting.

The installation of the electric light at Grays will, it is expected, be completed by the end of August. The Urban Council has decided to give the Gas Company notice to terminate their contract on June 30th.

A Local Government Board inquiry has been held in Bleckheaton in reference to an application of the District Council to borrow £25,000 for the purpose of electric lighting and the provision of a refuse destructor.

Dartmouth Gas Company has issued its annual report. From it it appears the cost of coal has been £600 more than last year, and the directors are not prepared to recommend more than a dividend of five per cent. For many years past the shareholders have received ten per cent.

Considerable advances have been made in the electric light scheme at Worthing, which is being carried out at a cost of more than £30,000, and an expenditure of close upon £6000 is contemplated at the corporation baths, medical baths being an important feature of the proposed provision.

The extensions at the Coatbridge Gasworks, which cost £20,000, are worthy of note, in so far that the new holder, weighing 200 tons, instead of having pillars and girders, has rails and pulleys, on which it moves up and down. This method is quite new, and the patent rights have been secured by Dempster, Limited, of the Langloan Ironworks.

By the end of September we understand the Hackney Borough Council expects to be in a position to supply electric light. In order to secure a large demand it has decided to enter into an agreement with a firm for the free wiring of consumers' premises at a rate not exceeding 2s. per lamp installed per annum. The Committee discovered that it had not the power to do this work itself unless paid for out of the current rates.

The Morecambe District Council held a special meeting last week, in committee, to complete the arrangements for formally acquiring and taking over the Gas Works from the Morecambe Gas and Light Company, Limited. The solicitor to the Gas Company, delivered the said conveyance to the Council, and received in exchange for the same the foregoing mortgages amounting to £141,000. He also handed to the Council a receipt for the sums of £1104 15s. 6d. and £5895 4s. 6d. in exchange for the said mortgages for £7000.

The Holborn Borough Council has written the Kensington Borough Council stating that it has considered the resolutions passed at the conference of local authorities held in October, 1900, by the London County Council and the Corporation of London on the subject of the charges for gas, and approved of the taking of active steps by the latter authorities to protect London gas consumers and to oppose the grant by Parliament of further powers to metropolitan gas companies unless and until due redress of the existing grievances be obtained.

GENERAL.

The Wilton Town Council has decided to adopt the Wash-houses and Baths Act.

The Eastbourne Town Council has decided to build a branch public library and baths at seaside at a cost of £2000.

The Stafford Town Council has received the sanction of the Local Government Board to the erection of artisans' dwellings.

The Hanley Town Council has accepted the offer of the Horsfall Destructor Syndicate to provide a refuse destructor for £5000.

The Woolwich Borough Council has selected a site in High-street, Plumstead, for the erection of a public library, baths, and other municipal buildings.

A Local Government Board inquiry has been held into the application of the Royston, Ashwell, Melbourne Joint Hospital Board for a loan of £3000 for an infectious diseases hospital.

The Glasgow Health Committee, after considering a report by its Health Officer, has resolved to take no action with reference to the Trades Council letter alleging danger to the health of the community by drinking aërated waters from glass-stoppered bottles.

The London County Council has decided to lend the Hampstead Borough Council £4385 for a dust destructor, and the Battersea Borough Council £3615 for building and paving works.

Although it is rather late in the day, the industrial burgh of Clydebank is stirring itself on the question of an ambulance corps. It is hoped that the nucleus of this necessary movement will be found in the Kilbowie ambulance class, and a committee has been appointed to confer with the employers of labour on the question. Besides the necessary appliances, a wagon will also be aimed at, as there is no public one in the burgh, although the shipyard and the factory both possess these conveniences.

At a recent meeting of the Cleansing Committee of the Aberdeen Town Council the offer of Messrs Scott and Son, amounting to £162, and of Messrs Twyfods, Limited amounting to £161, was accepted for the reconstruction of conveniences at Flour-mill-lane and Short Loanings. In connection with the proposed purchase of a refuse destructor at the police stables, the Committee resolved to visit the Esplanade and ascertain the amount of refuse that could yet be deposited there, so as to enable them to present a report on the whole question to the Council.

As previously announced, a British Congress on Tuberculosis, of which King Edward is patron, will be held in the Queen's Hall, London, from Monday, July 22nd, to Friday, July 26th, this year. The work of the Congress will be divided into four sections, as follows:—(1) State and Municipal, presided over by Sir Herbert Maxwell, M.P.; (2) Medical, including Climatology and Sanatoria, Sir Douglas Powell presiding; (3) Pathological, including Bacteriology, president, Professor Sims Woodhead; (4) Veterinary, tuberculosis in animals, president, Sir George Brown. Public addresses will be given to the whole Congress on July 23rd, by Professor Koch, of Berlin; on the 24th, by Professor Brourdel, of Paris; and on the 25th, by Professor McFadyean, of the Royal Veterinary College. The Earl of Derby has intimated his desire to receive the members at an evening reception to be given by him.

At the last monthly meeting of the Carnoustie Town Council a voluminous correspondence was submitted on the question of an emergency hospital for small-pox, free re-vaccination, and a permanent infectious diseases hospital. The Local Government Board requested plans of the proposed hospital, and urged that free re-vaccination be at once offered. Regarding the proposal to use two houses in Yeaman-street for the isolation of small-pox, the Board expressed the opinion that the proposal seemed a highly dangerous one, and requested a report thereon from the Medical Officer. Dr. Dickson thereupon reported that the houses in question were not suitable, and proposed the immediate erection of an isolation hospital. The Town Clerk of Monifieth also inquired the views of the Town Council of Carnoustie upon the question of a combination hospital for small-pox. Subsequently Dr. Dickson reported his preference for a site for the infectious diseases hospital on the Carnoustie estate behind Viewbank, instead of at Pitskelly, as formerly advocated and elaborately reported upon. In reply to a question whether small-pox cases could be treated in an infectious diseases hospital, the Local Government Board stated that that could be done only when all other infectious cases are excluded. The minutes of the Committee were approvod.

The St. Bride's Press, Limited, 24, Bride-lane, Fleet-street, London, E.C., are about to publish a work on "Quantities," by J. Bartlett, M.S.A., member of the Council of the Society of Architects. Vol. I. (ready April 15th) deals with quantities as applied to road making and sewer construction, and should prove extremely useful to surveyors, municipal and consulting engineers, contractors and others. It will be on sale at 10s. nett.

PERSONAL.

Mr. T. B. Young has just been appointed manager of Dollar Gasworks.

Mr. Maxwell has been reappointed Surveyor for the rural district of Gainsborough.

Mr. Leonard Gibson has been reappointed Inspector of Nuisances for the urban district of Hessle.

Mr. P. M'Farlane Cram has been appointed Road Surveyor and Sanitary Inspector for the county of Nairn.

Mr. Simmonds has been re-appointed Inspector of Nuisances for Eaton at a salary of £62 10s. per annum.

Dr. F. J. Sadler has been appointed Medical Officer of Health for the rural district of Barnsley, at a salary of £40 per annum.

Dr. H. Ruskin Hancock has been appointed Temporary Medical Officer for the Leicester Isolation Hospital, in room of Dr. Monk.

Dr. T. Bamford has been appointed Medical Officer of Health for the rural district of Uttoxeter in place of Dr. Herbert, resigned.

Dr. P. E. Hill has been appointed Medical Officer of Health for the rural district of Crickhowell, at a salary of £50 per annum.

The Local Government Board has sanctioned the appointment of Mr. Ransome as Medical Officer of Health for Southgate for the next year.

Mr. Marshall, of Fenton, has been appointed Sanitary Inspector and Road Surveyor for the urban district of Uttoxeter, at a salary of £140 per annum.

The salary of the Surveyor and Gas Engineer to the Great Malvern Urban District Council (Mr. H. P. Maybury) has been increased from £450 to £600 per annum.

Dr. Williamson and Dr. Cheetham have been reappointed Medical Officers of Health for Wharfedale, and Messrs. Slater and Morfitt Sanitary Inspectors.

Mr. J. W. Bradley, Borough Engineer of Wolverhampton, has been appointed City Engineer and Surveyor of Westminster, at a salary of £1000 per annum, rising to £1200 in four years.

Dr. R. H. Townend, of Skelmanthorpe, has been reappointed Medical Officer of Health for the urban district of Emley, and Mr. Mountain has been appointed Inspector of Nuisances.

Dr. Robert Smith, who graduated in 1894 and took the diploma in public health in 1899, has been appointed Medical Officer of Health to the borough of Rawtenstall, with a population of 32,000; and Dr. Robert S. Trotter, has been elected to the Medical Officership of Bedlington.

OBITUARY.

DR. MURRAY MACKAY.

A highly respected North Shields medical man in the person of Dr. Murray Mackay died at his residence in Northumberland-place on Thursday, the 28th ult. He came from Fifeshire to North Shields fourteen or fifteen years ago, and was subsequently for a long time one of the Medical Officers for the Tynemouth Union. He was only confined to his house a week before he died, so that the news of his death came as a surprise to many. The deceased leaves a widow and family.

LAW CASES.

Interesting Smoke Prosecution.

The Times Mill Company, Limited, Tonge Springs, were summoned by the Middleton Corporation for smoke nuisance. The fact that an order had been made on the company having been proved, Mr. Norton said he took an observation of the defendant's chimney on February 25th from 2.10 p.m. to 3.10 p.m., when there were 14 min. 35 sec. black smoke, 20 min. 42 sec. moderate, 21 min. 58 sec. slight, and 2 min. 43 sec. no smoke.

Mr. Wardle (manager): You remember that day seeing our smoke-preventing appliances?

Mr. Norton: I don't admit they are smoke preventing.

But you know that the construction of the fire-bars is such that the man cannot coal heavily?—No, I do not. He can fire heavily if he wants.

Do you remember that when you saw them the fires were burning brightly?—Yes.

And do you know when they burn brightly like that you cannot make black smoke?—You can if you put coal on.

Mr. Norton added that the Corporation did not wish to be hard, but this was about the worst chimney in Middleton. This was rather singular, because it used to be one of the best. Up to recently there was very little trouble with the chimney.

Mr. Ramsbottom: You have a time limit?

Mr. Norton: We allow them ten minutes in the hour. Very few Corporations allow such a length of time as the Corporation of Middleton. I don't think they can complain as to that. It is not economy for them to send up black smoke, because it is unconsumed fuel.

The Chairman: In the eyes of the law there is no such thing as a time limit for black smoke.

Mr. Wardle said the firm had done all they could do, and gone to great expense with smoke-preventing appliances. They had a guarantee from the man who put in the present appliances to pay all fines if the other boilers using the chimney had the same appliances on. Mr. Wardle said they could do no more. It was really painful to be brought there nearly every week, and it looked malicious.

The Chairman: The law is there, and we have to administer it. The Bench have decided to fine you 10s. and costs. Seeing both firms used one chimney, it would be better for one of you to build a new one.

The Middleton and Tonge Cotton Spinning Company were fined 10s. and costs.

Temperature of Workrooms.

At Marylebone Police-court, Sussanna Barnes, milliner and dressmaker, Holles-street, appeared to answer four summonses under the Factory and Workshops Act for neglecting to take adequate measures to secure and maintain a reasonable temperature in the workshop where her assistants were employed.

Mr. Walter Stewart defended.

Miss Lucy Deane, an Inspector under the Act, explained that the workroom was a large apartment on the second floor, in which there were two fireplaces, one of which was sealed up. The only means employed for heating the room was an asbestos stove. Twelve young women were employed there, and on each of the three occasions that she visited the premises the room was noticeably chilly, and the young women appeared to be cold and uncomfortable. The temperature was, on the respective days, 50 deg., 55 deg., and 51 deg. Fah., whereas it should have been between 60 deg. and 65 deg. Fah. After her third visit all the young women were put into one part of the room nearer the stove, but that merely overcrowded that part and did not remedy the evil. The object of the Act, she added, was to prevent young women who came long journeys through the rain or snow having to sit in their damp clothes in a cold room.

Dr. T. M. Legg, Medical Inspector of Factories to the Home-office, and Dr. Wynter Blythe, Medical Officer of Health for Marylebone, expressed the opinion that a "reasonable temperature" in a workroom where the occupation was a sedentary one, was 60 deg.

Mr. Stewart submitted, in defence, that there had been no contravention of the Act. None of the young women, he said, had suffered any ill-effect from the temperature at which the room was kept. All of them had, in fact, been able to do some of the finest needlework possible, which could not have been done had their fingers been cold. He contended that this was a fussy prosecution. Several of the young women were then called. Most of them gave a qualified opinion as to the comfortable state of the room, but two of them frankly admitted that where they had had to work it was cold.

Mr. Curtis Bennett said the case for the prosecution had been proved by the defence. There was no doubt the temperature was too cold; 60 deg. was by no means excessive. The defendant, having to move about to wait on customers, might keep warm enough herself, but the poor girls sitting at their work hour after hour might be shivering with the cold. In his opinion the defendant was an obstinate person who defied the Act, and rather than unblock a fireplace and put a fire there, she compelled the girls to go into one part of the room, and even there the temperature was not warm enough for those farthest from the fire. He should not fine her this time, but under the first summons he should order her to put her workroom into conformity with the Act within six months, and pay £3 5s. costs. The other summons would be adjourned *sine die*, and if the order was not carried out a penalty of £1 a day would be imposed.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2148.—Lock-up Shop: Whether a Dwelling-house.—"Surveyor" writes: — Finding your 'Notes and Queries' column very useful and instructive, I should be greatly obliged if you could advise me on the following, viz.:—In my district, which is an urban one, the occupier of a lock-up shop is sleeping in the same, and as he has no other place or lodgings I presume he is using it as a dwelling-house. Town water is laid on to the shop. Would you please advise me what powers my Council have in a case like this?"

Answer.—The building in question is a dwelling-house, and the Council have all the powers in relation thereto which they have in regard to ordinary dwelling-houses, such as enforcing the requirements for w.c., e.c., or privy and ashpit, drainage, water supply, ventilation, &c. It is also a "dwelling-house" within the provisions of the Building Bye-laws. If there should be any matters in relation to the sanitary condition of the house as to which the querist is in doubt we shall be pleased to further advise him if required.

2149.—Payment by Commission to Officers Illegal.—"Surveyor" writes:—"Under the terms of my appointment as Surveyor, the preparation of plans does not form part of my duties, and previous to my appointment the work was entrusted to an outside engineer, but since I have been Surveyor I have prepared plans for various public works, and am now asking my Council for payment. According to the note, Section 193, on Lumley's Public Health Acts, it appears that gratuities for extra services may be disallowed by the auditor, and also that payment by commission is illegal. It would thus seem that the only legal way to remunerate me would be to raise my salary for the current year by an amount equal to the amount of commission

due. Is this so? I notice, however, that two or three Urban District Councils have only recently paid their surveyors by commission for the preparation of plans. (2) Please also state whether an officer, if appointed full time, can be prevented from devoting his spare hours (evenings, holidays, and perhaps Sundays) to private work."

Answer.—(1) The Local Authority may make extra payment for extra work carried out by their officers provided the work is clearly extra, but such payment should not be made by way of commission. The amount to be paid may, however, be equal to a sum which would be earned by payment by commission. The Authority may in the alternative increase the officer's salary on account of the extra work cast upon him, and to which increase he is clearly entitled. (2) When an officer is appointed to devote the whole of his time to the duties of his office, it is implied that he is not to engage in private practice. A Local Authority cannot, however, control the manner in which an officer is to devote his leisure hours, so long as he does not engage in work inconsistent with the terms of his appointment. Thus, it would be improper for a surveyor to prepare plans for new streets and buildings to be submitted to his own Authority.

2150.—Factory and Workshop Inspector's Qualifications.—"W. E." writes:—"Could you please inform me what is the routine to be followed in qualifying for a Factory and Workshop Inspector?"

Answer.—Candidates for appointments as Factory Inspectors are nominated by the Home Secretary, but must also undergo a competitive examination, held by the Civil Service Commissioners. The subjects of the examination will be found fully detailed in our reply to Query 1485, in our issue of May 26th, 1899.

2151.—Cements: Where Obtainable.—"D. J." writes:—"Will you be good enough to inform me where I can obtain a few samples of the following kinds of cement, viz.: Portland, Keen's, Martin's, Parian, and Roman cement?"

Answer.—The querist will be able to obtain such samples from any reputable local builder, plasterer, or ironmonger. Although the whole of these kinds may not be kept in stock by any local builder, &c., he could doubtless obtain some for him.

2152.—Erecting Building over Sewer in Urban District.—"M. O. H." writes:—"In this urban district a plan has been submitted to the Council for the erection of a coal store over a public sewer, which is a 2ft. stone culvert about 2ft. below ground level. The owners are willing to cover in the sewer with concrete. I am disposed to sanction the arrangement, but wish to know (1) Whether, under Sec. 26 of the Public Health Act, 1875, the owners can be prevented from building a store over a sewer? (2) Whether the Council can demand a guarantee that the store shall not at any future time be closed, but that it shall remain as now proposed with open sides?"

Answer.—(1) The Urban Authority have absolute power of refusal to allow the construction of the coal store, which is a building over the sewer, and if the owners proceed to erect the building without the written consent of the Authority, they will be liable to the penalties prescribed by Sec. 26. (2) The Council may give their consent, subject to the conditions suggested, but the Council should take a bond for the due performance of the agreement.

2153.—Sanitary Conveniences in Factories and Common Lodging-houses.—"S. D." writes:—"Is there any bye-law, memorandum, or regulation, issued by the Local Government Board requiring the provision of a sufficient number of water-closets in factories and common lodging-houses?"

Answer.—As regards the provision of sanitary conveniences in factories, Local Authorities are enabled, on the report of their surveyor, to require the construction of a sufficient number of water-closets, &c., for each sex in any factory or building in which persons of both sexes are employed. Where the Public Health Acts Amendment Act, 1890, is in force, Sec. 22 of that Act prescribes that:—"Every building used as a workshop, or manufactory, or where persons are employed in any trade or business, &c., shall be provided . . . with sufficient and suitable accommodation in the way of sanitary conveniences, having regard to the number of persons employed, or in attendance at such building, &c." Similar powers are also given under Sec. 35 of the Factory and Workshop Act, 1895. As regards common lodging-houses, where such houses are registered, the Local Authority may enforce the provision of such a number of closets as in their opinion is reasonably necessary. The bye-laws as to common lodging-houses contain clauses prescribing that sanitary conveniences shall be kept in a cleanly and wholesome condition.

2154.—Separate Cesspools for New Houses may be Enforced.—"Surveyor" writes:—"(1) In a district where no sewers are available, can a Rural District Council reasonably require a cesspool for the drainage of each house, so that each occupier may be made responsible for the emptying of the same? (2) Would the Council be empowered to refuse approval of plans where four drains are shown to discharge into one cesspool, on the ground that the proposed method of drainage is unsatisfactory? I refer you to Sec. 25 of the Act of 1875."

Answer.—(1) It should be observed that Sec. 25 of the Act of 1875 applies to urban districts, and we are not informed whether the Rural Council have been invested with urban powers in relation thereto. Inasmuch, however, as the owner proposes to drain the houses, the Rural Authority are enabled to exercise their powers of approval or disapproval in the case named, and they may enforce the provision of a separate cesspool for each house, the words of Sec. 25 and also Sec. 23 being that the drains shall empty into such covered cesspool as the Authority direct. (2) Yes.

2155.—Combined Drainage: Whether Drain or Sewer.—"S. P." writes:—"I shall be glad if you will inform me whether a combined drain which receives the drainage of three houses belonging to two different owners is a sewer or a drain. The P.H.A.A, 1890, is in force."

Answer.—It is probable that the length of drain from A to the party fence between the two houses belonging to one owner is a sewer. That portion of drain within the premises of No. 21 is undoubtedly a drain. We advise the Local Authority to serve the owner with notices under Sec. 23 of the Act of 1875 to provide a sufficient drain or drain for the two houses, *i.e.*, from A to B, and let the owner establish proof that any part of it is a sewer.

2156.—Public Analyst: Qualifications for.—"A. S. I." writes:—"Under the recent Order issued by the Local Government Board concerning the qualifications required by public analysts under the Food and Drugs Acts, would a D.P.H. be sufficient, providing he had sufficient knowledge of chemistry?"

Answer.—In our opinion, the possession of the Diploma of Public Health, without other certificates or diplomas, will not satisfy the requirements of the Local Government Board that the person is competent to act as public analyst. The Order of the Local Government Board, dated March 7th, 1900, making regulations as to the competency of public analysts appointed under the Sale of Food and Drugs Acts, 1875 and 1899, provides that—"Every person appointed on or after Jan. 1st, 1900, shall furnish such proof as we may deem sufficient of his competent skill in and knowledge of (*a*) analytical chemistry; (*b*) therapeutics; and (*c*) microscopy. Such proof shall in every case comprise documentary evidence that such person holds the requisite certificate, diploma, service, or document, conferring the qualification, or attesting his possession of the skill or knowledge to which the same applies, and granted or issued by any person or body of persons for the time being recognised by us as competent to confer such qualification or to test such skill or knowledge. Such proof shall also comprise such further evidence as we may in any particular case require."

2157.—Laying Out New Street: Meaning of Term Width at Entrance.—"Retrogressive" writes:—"I submitted the enclosed block plan of a field which I propose to lay out for building to an Urban District Council. The plan has, however, been rejected on the grounds that it contravenes the following bye-law, viz., 'Every person who shall construct a new street shall provide at one end at least of such street an entrance of a width equal to the width of such street, and open from the ground upwards.' The street to be laid out by me is of the full width, but the street leading to it is only 17ft. 6in. wide, does not belong to me, and I have no power to widen it. Kindly advise if the Urban District Council have power to reject my plan on these grounds. If they have this power, who is to make street, which does not belong to me, to comply with the bye-laws?"

Answer.—The Council are enabled to refuse approval of the plans on the grounds that the entrance to the new street is not of the width required by the bye-laws, notwithstanding that the road opening into the proposed new street may be a public highway of less width than that required by the bye-laws. See Barton Regis Rural District Council *v.* Stevens and others (1897), 61 J.P., 598, where it was held that the person who proposes to construct a new street shall, before he can be allowed to make it, provide an entrance to it of equal width with the street. We feel bound, however, to point out that the bye-law is one which is rarely insisted on, and recognising the hardship which it is likely to entail in some districts, the Local Government Board now approve a clause as an addition to that quoted by the querist as follows, viz., "Provided that where such street shall communicate with some other street, it shall suffice if he shall so construct such new street that at the point of communication it shall be open from the ground upwards to the full width thereof." In order to overcome the difficulty in the case cited by the querist, we may point out that he may proceed with the erection of one or more dwelling-houses after submitting plans to the Local Authority. The approval of not more than three buildings at a time should be sought, and inasmuch as the

OFFICIAL APPOINTMENTS

BOROUGH OF KENSINGTON.—APPOINTMENT OF SANITARY INSPECTORS.

The Council of the Borough aforesaid are prepared to receive APPLICATIONS for the APPOINTMENT of FOUR SANITARY INSPECTORS.

Persons applying must be between 25 and 35 years of age, and must be on the Register of the Sanitary Inspectors' Examination Board, which includes persons who obtained Certificates of the Sanitary Institute prior to the 31st December, 1899.

The persons appointed will be required to reside in their respective districts, to wear a plain uniform, and to devote the whole of their time to the duties of the appointment. Salary £150 per annum, rising by conditional annual increments of £10 to £200.

The appointments will be made subject to the approval of the Local Government Board, and in accordance with the Sanitary Officers (London) Order, 1891, and preference will be given to candidates having had practical experience in some branch of the building trade.

Applications must be made in the candidate's own handwriting on printed forms to be obtained of the undersigned at the Town Hall, Kensington, and must be delivered at my office not later than Twelve o'clock noon on Saturday, the 27th April, 1901, accompanied by copies of not more than three testimonials of recent date.

The appointments will be made by the Council on the 15th May, 1901.

Personal canvassing of any Member of the Council will be a disqualification.

WM. CHAMBERS LEETE,
Town Clerk.

Town Hall, Kensington, W.,
10th April, 1901.

BOROUGH OF KENSINGTON.—APPOINTMENT OF LADY SANITARY INSPECTOR.

The Council of the Borough aforesaid are prepared to receive APPLICATIONS for the APPOINTMENT of an additional LADY SANITARY INSPECTOR, for the better enforcement of the sanitary provisions of the Factory and Workshops Acts, and the Public Health (London) Act, 1891, in workshops, workplaces, and laundries in their Borough, where women are employed.

Candidates must be between 25 and 35 years of age, either single or widowed, and must be on the Register of the Sanitary Inspectors' Examination Board, which includes persons who obtained certificates of the Sanitary Institute prior to the 31st December, 1899. The person appointed will be required to devote the whole of her time to the duties of the office, and to reside in the borough. Salary £110 per annum, rising by conditional annual increments of £10 to £150.

The appointment will be made on the 15th May, 1901, and will be during the pleasure of the Council, and subject to the approval of the Local Government Board.

Forms of application, with list of duties, can be obtained of the undersigned at the Town Hall, Kensington, and must be filled up in the candidates' own handwriting, and returned to me not later than Twelve o'clock noon on Saturday, the 27th April, 1901, accompanied by copies of not more than three testimonials of recent date.

Personal canvassing of any member of the Council will be a disqualification.

WM. CHAMBERS LEETE,
Town Clerk.

construction of such cannot be deemed to be the laying out of a new street, the Authority will not be able, assuming that the bye-laws with regard to the buildings are complied with, to prevent their erection.

2158.—Assistant Inspector of Nuisances Cannot Sign Statutory Notices.—"T. H." writes:—"Is it competent on the part of an Assistant Inspector of Nuisances to sign his own name to statutory notices requiring the abatement of nuisances, or should the notices be signed by the Chief Inspector?"

Answer.—No. Such notices must be signed either by the Clerk or Inspector of Nuisances. Notices signed by an Assistant Inspector of Nuisances would be invalid. See Section 266 of the Public Health Act, 1875.

2159.—Bacterial Sewage Installations: Places Where Adopted.—"D. O." writes:—"A deputation from the Sewage Committee of this town are about to visit towns where installations of bacterial treatment of sewage have been laid down. Would you kindly suggest a number of towns which it would be advisable for them to visit, more especially where open and closed septic tanks are in successful operation?"

Answer.—Installations for the treatment of sewage on the double contact or Sutton system, and with or without open or closed detritus or septic tanks, are in existence at Sutton (Surrey), Worcester Park, Leeds, Manchester, Oswestry, Alton, Harrow, Haywards Heath, Hampton, Maidstone, Aylesbury, St. Albans, Crossness, Barking, Blackburn, Carlisle, West Bromwich, Guildford, Croydon, Epsom, &c. A fuller list may, we think, possibly be obtained from Messrs. Dibdin and Thudichum, consulting and analytical chemists, 2, Edinburgh Mansions, Howick-place, Victoria-street, London, S.W. For particulars as to places where the septic tank system is adopted we advise the querist to communicate with Messrs. Cameron, Commin, and Martin, 7 and 8, Bedford-circus, Exeter.

2160.—Gipsies: Nuisance: Housing of the Working Classes Act, 1885.—"H. F." writes:—"In my district a gipsy with three vans has settled on a village green, and has been there for four years. The green belongs to two Lords of the Manor, and neither knows exactly his own portion. Will you please inform me—(1) Can the Local Authority insist on 300 cubic feet for each adult? (2) Having no privy or w.c. accommodation, can the Local Authority serve notice under Sec. 91 of the Act of 1875, to erect a properly constructed privy, so as to prevent the nuisance caused through want of proper privy accommodation? The Local Authority will not take any steps under Sec. 36 of the Act of 1875, as the vans will move off when the Local Authority erects a privy. (3) What other steps can be taken with a view of clearing them off the green?"

Answer.—(1) Sanitary Authorities have control over vans occupied by gipsies, &c., for human habitation under Sec. 9 of the Housing of the Working Classes Act, 1885. The Medical Officer of Health and Sanitary Inspector should inquire into the capacity of the said vans, and if, in their opinion, the vans are so overcrowded, or they are in such a state as to be a nuisance or injurious to health, the Local Authority may institute proceedings for a nuisance under Sec. 91 of the Act of 1875. (2) The Local Authority may enforce the provisions of the Acts in regard to water supply, drainage, and w.c. or privy accommodation, for we assume that none of these are already provided. Proceedings should be taken under Sec. 91 of the Act of 1875. (3) The enforcing of the provisions of the Elementary Education Acts is often of considerable service in securing a removal of these unsatisfactory neighbours. The Local Authority may also make bye-laws under Sec. 9 of the Housing of the Working Classes Act, 1885, for promoting cleanliness, &c., in tents, vans, sheds, &c., used for human habitation. In the case of "Attorney-General *v.* Stone and others, 60 J.P. 168," an injunction was granted against the owner of land for restraining him from allowing it to be occupied by gipsies in such numbers and in such a manner as to be a nuisance to the neighbourhood. The nuisance was said to be caused by the insanitary condition of the land—the absence of proper drainage, overcrowding, dirt, noise, and untidiness.

2161.—Trespass: Erecting Building on Wall of Neighbour's Property: Scope of these Columns.—"Ynys" writes: "A is the owner of a leasehold house and garden. The latter is bounded by a wall built on his ground as per lease. B built a house adjoining the premises belonging to A, and some time later B became anxious to build a back kitchen at the rear of his house, and incidentally meeting the father of A (who is a widow) asked his permission to build the back kitchen on the garden wall belonging to A. The father of A said that B might do so as far as he knew, and on the strength of this verbal promise B built the back kitchen. A did not see this done until she called some twelve months later, when she was surprised to find such building erected on her wall, but made no protest. A subsequently sold the house to C, who desires now to establish his claim to the garden wall on which the back kitchen was built—eleven years ago. The question is: Can C claim compensation for building this back kitchen partly on his premises after a lapse of eleven years since it was erected? If so, what steps should C take to recover compensation?"

Answer.—This question is one which does not fall within the scope of these columns, which are restricted to questions on municipal and sanitary engineering and Public Health law. The querist should consult a local solicitor.

SANITARY CERTIFICATES FOR SEASIDE RESORTS.

The system of issuing sanitary certificates to keepers of hotels, boarding-houses, &c., has been found so workable at Eastbourne that we make no apology for printing the subjoined list of requirements which might well serve as a guide to other health resorts we could mention. Such a system must of necessity increase the popularity of any resort where it is in vogue, offering as it does, guarantee to each visitor, of immunity from the risks of disease.

SANITARY CERTIFICATES—SPECIFICATION OF REQUIREMENTS.

(1) *Drains* to be of glazed stoneware or cast iron pipes with protective composition, having an internal diameter of not less than 4in.; to be laid in straight lines with regular and equal fall of not less than 1½in. in 10ft., and to be imbedded in concrete; to be provided with intercepting syphon, manhole and through ventilation, and to be outside the buildings if possible, if not, to be of iron and bedded in concrete. All joints to be proved sound by the "water test."

"*Drains*" applies to the whole drain from house to sewer. (If, however, the intercepting syphon is at the boundry of the premises and sufficiently far from the house, and if in such a case the drain beyond the intercepting syphon is found to be of good fall and working well, the part beyond the intercepting syphon need not be re-laid.)

"*Drains*" also applies to drains of stables or other drains in the same curtilage. Drains of stables or other buildings are to be effectively cut off from the dwelling-house drainage system. Inspection manholes, built with and rendered out with cement and sand, or of glazed brickwork and cement, to be provided at each change in direction of the drains and also at the intercepting syphon. The frame and cover to be of iron and the cover to be sealed down after final examination. The intercepting syphon to be as far from the dwelling-house as possible; the cap of the clearing eye to be securely fixed and air-tight in socket. Rain-water drains to be proved sound by water test unless proved to be in good working order and quite cut off from any other part of the drainage system.

(2) *Soil-pipes* to be outside; to have an internal diameter of not less than 3½in. (N.B.—Bye-laws for new houses, 4in.); to be carried up full size to just above the level of ridge of roof, and to have the fewest possible bends and angles; closet connections are to be drawn lead T-pieces. No seamed pipe permitted. Soil and ventilating pipes, if lead, to be at least 7 lb. to linear foot for 4in. pipe; if iron, to be at least 54 lb. to 6ft. length, with wide sockets; above the topmost closet connection the weight may be medium, the diameter remaining the same. In each case to end in a vertical position. Joints: whenever a stoneware trap or pipe is connected with a lead soil-pipe, between the two must be inserted a brass socket or other similar appliance; the stoneware end is to be inserted into the socket and the joint made with Portland cement; the socket is then to be connected with the lead pipe by means of a wiped joint where iron to lead sockets are to be used. Where a stoneware pipe or trap is connected with an iron soil-pipe or drain, the stoneware trap is to be inserted with a socket on the iron pipe and the joint made with Portland cement. Joints of iron pipes to be of caulked lead or other as satisfactory jointing material; red lead not sufficient. Stoneware traps inside a house will not be allowed unless of particularly satisfactory form. All solder joints to be "wiped plumbing" joints. In case of iron pipes, inside to be coated with protective material. The joints of soil and ventilating pipes to be proved sound by the smoke machine.

(3) *Ventilation of drains.*—Drain ventilation to consist of inlet and outlets, with outlets at the heads of the system to just above the level of ridge of roof; the soil-pipes to be additional to these outlets unless the former are at the heads of the drain system. Ventilation pipes to have a minimum internal diameter as in soil-pipes above.

(4) *Water-closets.*—Closet seats to be hung; lead safe, with outgo into open air having hinged flap at its end, to be laid over the whole of the floor space under the closet casing, unless the floor is of impervious material; walls under closet seats to be properly plastered. Traps and water-closets to be of approved self-cleansing form. The closet chamber to have proper means of ventilation; 2in. anti-syphonage pipes to be provided to each closet trap if the closets are in tiers. Such pipes to be carried out at once, and to terminate in soil-pipe at least 1ft. above the topmost closet connection.

(5) *Housemaids' slop sinks*, where they exist, to be constructed in every respect as water-closets.

(6) *Closet-flushing services.*—Cistern to be absolutely distinct from domestic service; 1¼in. pipe and valve to be fixed if the hydrostatic head be under 10ft.; 1in. pipe and valves may be used for heads of 10ft. and upwards. Flushing cisterns to be of three gallons capacity and syphonic.

(7) *Domestic water supply.*—A tap from the main to be over a sink and marked. Cistern, of proper size, to be provided complete with overflow and cover, in a suitable position, free from liability to fouling and effluvia.

(8) *Waste pipes* to be trapped immediately beneath the fittings, and to discharge over, or into gully traps in the open air. The waste pipes to be taken at once into the open air and with the traps to be not less than 1½in. diameter for baths, 1¼in. for washbasins, 1½in. for scullery, and 1½in. for pantry sinks.

(9) *Rain-water pipes* to discharge over or into gully traps unless carried to a rain-water tank, the overflow from which is to be into the open air in a suitable position.

(10) *Gully traps* to be of round way form; no such traps to be inside the house or any building connected with the house.

(11) *Dustbins* to be either brick-built rendered inside, provided with doors and coverings and floor to be above ground level, or galvanised iron receptacles with covers, to be in a suitable position.

(12) *Baths* when enclosed to have lead safe under the fittings.

(13) *Plan.*—A plan of the drainage system one-eighth scale to be deposited at the Sanitary Department.

CONDITIONS OF ISSUE.

The certificate to be void and to be returned to the Medical Officer of Health. (1) If any alteration be made in the drainage or sanitary arrangements without the approval of the Corporation. (2) If any defect be found in the drains or fittings subsequent to the issue of the certificate. (3) In any case not later than three years from the date of issue. The premises should be thoroughly re-examined at intervals of not more than three years, and the re-issue of the certificate will depend on the drains and fittings being again proved sound and in good working order. The issue of the certificate is to be an implied acceptance of these conditions.

As regards certificates which have been issued more than three years, a notice is sent to the owner or occupier of the house in question, offering re-examination and re-testing of the house, though this in the absence of any nuisance is, of course, not binding on the owner or occupier. The certificate bears on its face an abstract of the requirements, so that there is no doubt as to what the Authority certifies. The certificate is continually in

demand, and it is found that the house which has a certificate is more valuable than one which has not. This is no doubt partly due to the fact that the Committee makes no exception from the printed requirements, so that they can be depended on. Theoretical objections to their issue have from time to time been suggested, but the practical experience now is that they are of very great value and are issued with practically no friction.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

PRESIDENTIAL ADDRESS.

An ordinary meeting of the Incoporated Society of Medical Officers of Health was held on Friday at the rooms of the Royal Statistical Society, 9, Adelphi-terrace, W.C. The President, Dr. J. C. McVail, occupied the chair.

Dr. A. Wynter Blyth, Medical Officer of Health, Marylebone, was nominated and elected President-elect for the year 1901-2.

Dr. Groves reported that the Medical Officers' of Health and Sanitary Inspectors' Tenure of Office and Superannuation Bill was down for second reading in the House of Commons on the 22nd inst., and he briefly explained its provisions, which he said were in the nature of a compromise. He appealed earnestly to all the members to use any influence they might possess with members of Parliament to obtain support for the measure, which was of the greatest importance to the public health service.

The President then delivered his postponed presidential address, his subject being "The Ethics of Preventive Medicine." He said that the question "Is life worth living?" might be an occasional subject for disputation, but for the sanitarian that life is worth living must ever be the principle of all his work. Its denial could hardly be regarded as serious on the part of sane men, and belonged to a period of cynicism rather than to the domain of real and settled belief. The old saying that whatever is worth doing at all is worth doing well, applied to the living of one's life at least as much as to lesser things, and applies to it in all its aspects, physical, moral, and intellectual. These two axioms might be regarded as the twin basis on which had been erected the whole science and practice of public health and preventive medicine. How closely the moral and intellectual aspects of life are related to the physical need not be dilated upon, yet at the very beginning of any consideration of the ethics of preventive medicine and the scope of its operations there arose the question as to its moral influence. While none could doubt the mental and moral value of

BETTER SANITARY CONDITIONS,

it was open to argument that sanitary administration —the means by which better sanitary conditions are attained—may have in one direction a very demoralising effect. If too much be done for the individual by his governing body, whether central or local, might not his sense of personal responsibility be weakened, might he not be led into a position of unwillingness to act for himself, and to rely on Government to carry out duties which properly belong to him?

This question was part of the very wide and difficult subject of the proper limits of municipal socialism; where should the boundary be drawn between what a man ought to do for himself, on the one hand, and what the State or the municipality ought to do for him on the other? On some points, such as water supply, scavenging, lighting, and so on, the nation is now agreed. As civilisation advances, the mechanism of government, whether national or local, becomes more elaborate, and its functions more intricate and inclusive, so that the sphere of private responsibility is bound to become in these directions correspondingly narrowed. Long ago the State undertook the duty of looking after the poor and the education of the children; the provision of school books is now undertaken by some Boards, and a still further step was made in the provision of a mid-day meal, on the ground that, in the case of poor and ill-fed children, this is a natural corollary of compulsory education. Even tennis grounds, cricket pitches, and bowling greens had been provided in our public parks and recreation grounds, so that a cynic might say a return is being made to the old conditions under which Roman Emperors attempted to placate and cajole the population by gifts of bread and games. But the difference was obvious. The games in the Coliseum were spectacles for the entertainment of the onlookers, while the games of the municipalities are healthy exercises in which all may join. In many places the means of locomotion were in the hands of the Local Authorities, but he had not yet heard of a free service being provided, though in Glasgow this was being foreshadowed by a

DEMAND FOR FREE FERRIES.

If there are free bridges in one part, why not a free substitute for them in another? Such a service would be a very considerable development of municipal socialism. If a man may freely walk across a bridge, or be carried across in a ferry at the cost of the town, why should he not also be carried along the street? Why should not the tramway service be free? It was, he supposed, too early to talk of those travelling cavements described by the novelist of science, Mr. Wells. However, such means of locomotion as ferries and tramways had little to do directly with public health, but they might easily develop still further, so that the workers in the town might have the opportunity of a free suburban train or bus service, so that they could live their leisure in the fresh air. Closely connected with this was the question of house accommodation, and there was evidence that this subject was likely to be taken up at no distant date as a matter of Imperial concern. In endeavouring to mark the boundaries which should be set to such enterprises as these, various principles could be suggested. It is one of the

ESSENTIALS OF A BYE-LAW

made under an Act of Parliament that it shall be of general application; on the same lines it is said that national and municipal schemes in the direction of socialism should be such as must benefit whole communities and not mere individuals. Much depended as to whether direct or indirect benefit is meant. If direct benefit be meant, then not even the Poor Law nor the Education Acts could be justified, for only a small minority receive poor relief, and many persons have no children attending elementary schools. If indirect benefit is held to be sufficient then the scope of operations might be widened to almost any extent, as very little is done by either Parliament or Local Authorities in defence of which there could not be alleged an ostensible reason of some indirect benefit to all. Another principle that might be suggested is that such enterprises should by improving environment give every man a fair chance in life, but should leave the individual himself to take such advantages as he may of the opportunities given. Where, however, was the line to be drawn between environment and environed? Climate is environment, and in so far as it could be influenced they were on safe ground. In "Looking Backward" was sketched

A TYPICAL EXAMPLE OF FUTURE SOCIALISM,

a municipal umbrella to be thrown across whole streets in time of rain; but certainly the removal of smoke and dirt from the atmosphere of cities is a matter of

first importance, which was well within the range of practical effort. Next to climate the city itself is an inner layer of environment, and its conditions should be improved in every possible respect. Next came the dwellings; on these much had been said, much had already been done, and much more might be looked for. Clothing was the next, but no one had yet proposed that the State or the municipality should clothe its constituents, though many towns had provided laundries at which clothes might be washed; but that was not all, for the human body itself might be regarded as the inmost covering of the individual. For this layer of environment there are public baths for cleansing and exercise, in order to maintain its health and vigour. Then there was the soul, and surely here we have got away from environment; but no, religious ordinances are provided for the benefit of the soul. In face of all this, it would probably be admitted that attempts to measure the

TRUE FUNCTION OF PUBLIC BODIES

solely by the test of the improvement of environment are likely to be attended with considerable confusion, and to leave it open to every man to claim that his own particular scheme fulfils requirements. The reason why it had not been proposed that clothing should be a municipal duty was obvious — clothing was a thing which the individual could do best for himself. Here was a principle which should often be of use in deciding where to draw the line between corporate and individual action. His two first axioms were, first, life is worth living, and secondly, that life is worth living well. When a municipality undertook a duty which could be done best for himself by the private citizen, it was proceeding on lines at variance with the second axiom. Allied to this aspect of the question was the other point, whether modern sanitary administration must incidentally have a bad effect by weakening the sense of personal responsibility by

MINISTERING TO SELFISHNESS

and by diminishing self-reliance. His experience had shown that some people were only too ready to throw off their personal responsibility and even to demand remuneration for work which they ought to have been glad to have had the opportunity of doing on their own behalf. His four suggestions for making the boundary between individualism and socialism had been touched on, viz.: (1) That collectivist measures shall be of general application. (2) That they shall so improve the environment as to give every man a fair chance in life, but shall leave the individual untouched. (3) That they shall do nothing for the individual when he can do better for himself. (4) That they shall interfere as little as possible with the sense of personal duty and responsibility, and shall be careful not to encourage selfishness or pander to laziness. No doubt there were other suggestions, but it was obvious that none could be applied rigidly, and that the circumstances affecting the numberless social problems which offer themselves for solution are so various that each must be judged on its own merits, just as in the diagnosing of obscure disease every indication is to be carefully marked and weighed and the conclusion arrived at by attention to all the facts of the case. There must also be kept in view the fact that

NEW PROBLEMS

are not to be faced in a too timid or uncertain spirit, but that recognition must be given to the general tendency of the times to make the functions of the State and the municipality, more and more extensive and inclusive. The preservation and improvement of public health has long been regarded as well within even the narrowest boundaries, which could be drawn round the sphere of operations both of Central and Local Authorities, yet when consideration is given to the various classes of measures which can be taken to carry out this important purpose, we still find ourselves in the region of controversy, and there is little that sanitarians can do which is not on grounds of principle, or of results, or of both made the subject of hostile criticism. Busy men who are fully persuaded of the value of their work life, and knowing only too well that art is long and life is short, and judgment difficult, could give little heed to these criticisms, and could spare little time in attempting to confute the critics. Preventive measures could be divided into three groups, or regarded as the three walls which constitute the defences of the city of Hygeia, so pleasantly written of by the late Sir B. W. Richardson. The outer wall was sanitarian in the sense of cleanliness of air and water, food and soil, and so on; the middle wall was preventive inoculation, and the third wall was hospital isolation.

Having dealt with each of these divisions of sanitation at considerable length, Dr. McVail advocated that in practical sanitary administration they should take short views rather than long views, doing that which was to hand and could be done without waiting for grander and larger schemes. Short views were not the same as narrow views. They were on unsafe ground when they attempted to advocate legislation to make compulsory measures which science had proved to be of value. In such matters their official attitude should be not that of legislators but that of educators of legislators. They knew that certain things were good for health and certain things were bad for it, but it did not necessarily belong to them to say that the doing of one set of things and the avoidance of the other should be insisted upon by Act of Parliament. Their proper place was to tell the country and Parliament the exact facts regarding every such question, and use all the earnestness they possessed in impressing upon the public mind the scientific conclusions deducible from the facts, but it was not for them to say the law must be altered to give effect to the principles brought under notice. It was their duty to drive in the facts and leave to the legislature the duty of making laws based on those facts.

PROGRESS IS BUILT ON PROGRESS,

rule on rule, advance on advance, so that present measures are stepping-stones to still better measures in the future. In addition to the direct benefit which accrues to the living generation from improved sanitation, and in addition to the good which inhabitants of this country fifty years hence will derive from persistent development and improvement of environment, it would certainly be a gratification if sanitarians and all who are endeavouring to help humanity could feel that they themselves have acquired as a result of better air, food, and exercise. There efforts are to be of direct service in the future through the parents whose health is being helped transmitting by heredity some of the bodily conditions which they themselves have acquired as a result of better air, food, and water, and exercise. There was, however, much scientific controversy as to whether acquired qualities were transmitted as was the case with constitutional conditions, but whatever doctrine ultimately prevailed it seemed to him that their duty was just the same. They were not charged with the

RESPONSIBILITY OF THE FUTURE

of the whole human race; to assume such a function would be to demonstrate their own colossal self-conceit. Duty was more important than speculation, and they must continue to take short views of their work. Indeed, if ever there was to be any hope of realising the visions of the night, or turning into solid facts the dreams which young men dream—and there was nothing like a deep-seated belief in the value of one's work to make a man continue to feel young, notwithstanding all evidences to the contrary—and if ever long views are

to lessen their distance from us, it must be through unceasing energy in giving effect to short views. So that if we continue carefully to distinguish between the creed and the programme, there need be no hesitation in admitting that long views may help to frame the creed, if short views alone can be of use in filling up the programme. As a well-beloved teacher used to say

"TO REALISE THE FUTURE, EMPLOY THE PRESENT."

Their programme must be the conserving of health and the protecting of life, and the preventing of death whenever and wherever the opportunity can be found. To withhold a helping hand in the hope that some distant good may result would be to act on the doctrine that the end justifies the means; indeed, it would be worse, for there is no certainty that such ends would ever be attained by such means, and there is no certainty that they may not be attained and achieved by methods that lie beyond the scope of our knowledge. Setting their attention to its natural limits, let them do their work within those limits, saving one life by inoculation, another by sanitation, and a third by isolation. On these lines, and on these alone, is progress safe and sure; they might not bring the notoriety that hysterical and irresponsible sensationalism would ensure, they might not create the interest which properly attaches to such business-like thought and great scientific achievement, but whether crowned or crownless when we fall it matters not, so that God's work is done.

The address was received with prolonged applause, and a hearty vote of thanks was accorded to Dr. McVail.

SUCCESSFUL SEWAGE DISPOSAL AT BASFORD.

By Dr. GEO. BURY BRAY, M.O.H Basford Rural District Council.

IN my last annual report I foreshadowed an account of experiments Mr. Maylan and I had been carrying out at the Kimberley farm, as a result of our visit to various sewage farms in the country, and our attendance at Sanitary Congresses. To lead up to this account I think a short history of the farm is necessary. In 1884, owing to threatened legal proceedings in consequence of sewage pollution of running streams, Kimberley was sewered to the present farm; the main outfall sewer was provided with two manholes on the way, from both of which, by means of valves, the sewage could, when required, be diverted on to grass land for broad irrigation treatment. On arrival at the farm, the sewage was received into a rectangular tank (divided into three compartments) in which it was *occasionally* treated with lime; from this tank the effluent found its nearest way over the stiff clay land into the brook. In 1896, after a fruitless appeal to the Local Government Board for a loan, you had the three tanks converted into "Cosham's Tanks" (six instead of three), with the addition of a straining chamber, and a baffle race (the latter for the treatment of the sewage with Spence's alumino-ferric precipitant) and the tank effluent was to be distributed over *the stiff clay land* for final treatment. In my report for 1896 I wrote of this treatment;—"The effluent from these (Cosham) tanks is a remarkably good one, but from the nature of the sewage and the land at your disposal, I would strongly recommend the further treatment of the effluent by filtration, as I am certain the land is useless for the purpose."

After my visit to the Sanitary Congress at Leeds, in 1897, you granted me permission to put down a coal filter for the partial treatment of the tank effluent, and the result was satisfactory. In 1898, when Mr. Maylan became associated with me in the treatment of the Kimberley sewage, he entered into the subject with the greatest enthusiasm, and the present state of the farm is entirely due to his exertions. There are now four filters (or primary contact beds) for the first filtration of the day flow from the tanks, and one large one provided with stationary sprinklers for the second or final treatment. In addition there are two large primary contact beds for the first filtration of the night flow from the tanks, each provided with a large secondary filter. These latter are not at present provided with sprinklers, but we propose to add them later on. We also propose to make primary and secondary beds for the treatment of storm water, and also prepare a portion of the land on the south side of the brook, to take part of the sewage when necessary. It will, however, be necessary to have several more filters, in order not to overwork the existing ones, and also to be able to give any and each of them a rest periodically.

Our experiment began in December, 1899, when we gave up the use of chemicals and removed the screens, thus receiving chemically untreated, unscreened crude sewage in the Cosham tanks. After a short time, as no scum formed on the surface of the tanks, we duplicated the Cosham flocculent flues, and in three days' time a scum began to form on the first two tanks, and eventually it spread to all six; this scum remained and increased in thickness, the increase being most marked and most rapid on the first two, and gradually thinned off, till it was only three inches thick on the sixth tank, at which thickness it has remained now for some months. It was quite a month before solvent action took place, and nitrites appeared in the double-filtered effluent, but once they did appear they remained till the close of the experiment in November, 1900. At that date, owing to the filling up of the *first two tanks*, and the primary contact beds showing signs of clogging, it was decided to clean out those tanks and give the contact beds a rest. On cleaning out the two tanks it was found they were practically filled with a gelatinous homogeneous material of strong odour, and dark blackish colour, evidently the solid organic matter of the sewage undergoing putrefactive resolution changes. It has now been decided to use the first tank as a screen, from which the floating solid matter is removed daily, the other five tanks retaining their action as open septic tanks. During the time of the experiment daily thermometric readings were taken of the tank effluent, filtered effluent, and outside air, and from them we conclude we have nothing to fear from frost, as in the exceptionally severe weather of February, 1900, when the outside thermometer registered 32 deg. of frost on the 13th of that month, our lowest effluent reading was 41 deg., a temperature which does not prevent microbic action.

From the year's working at Kimberley Farm under the severe test we put it to, we have come to the following conclusions:—(1) That screening of the trade refuse is necessary, either at the source or at the farm. (2) That no chemical treatment is necessary, in fact it is retrograde and expensive. (3) That the tank capacity should be equal to at least three times the actual dry-weather flow, or an estimated day's dry-weather flow, based on 20 gallons per head per day, and that only that amount should be allowed to flow through in storm time. (4) That the night flow and storm-water overflow should be specially provided for and treated by double filtration. (5) That the primary filter beds for sewage treatment should be much more in area than is usually necessary for the ordinary treatment of the flow, to allow change and rest. (6) That the secondary filter beds should have the partially-treated effluent so distributed over them that efficient aëration is ensured. (7) That the sludge difficulty is relieved but not removed; there will always be a certain amount of sludge formed, its quantity being in inverse proportion to the efficiency of the screening and capacity of the tank.

THE SCOTTISH INSANITARY ONE-POUND NOTE.

The Scottish one-pound bank note has often been under suspicion as a convenient vehicle for the dissemination of infectious disease. The following remarks which occur in the annual report of Mr. George Mackay, chief Sanitary Inspector for Perthshire, give further currency to this idea:—

To the English traveller the issue and circulation of £1 bank notes in Scotland, he observes, had often given rise to feelings of surprise, mingled with those of disgust, as in this connection, he (the traveller) was not accustomed in his own country to bank notes for a smaller value than £5, which were never allowed in circulation the second time after being returned to the banks. They had in Scotland a vast number of these £1 papers in circulation, and while the most of them would be very pleased to be in possession of a few thousands of them, he was afraid that under certain circumstances there lay hidden within their crevices the dangerous microbe of scarlet fever, small-pox, or other forms of infection. This was not to be wondered at when they thought of the number of hands through which these notes have to pass; and it could be conjectured how easy it was to convey these disease microbes from either a recovered case of scarlet fever or small-pox to the innocent and unsuspecting person who handles the note shortly after. It was a customary practice among the general public to moisten the finger on their lips to facilitate counting, and thus convey whatever may be inimical to a sound body to the note, which may become a ready element in the conveyance of disease; but apart from the danger which may be apprehended from infectious disease, it must be confessed that when a bunch of these filthy notes is in the hands while in the operation of counting, it is a common occurrence to perceive a heavy and disagreeable odour.

The sanitary officer is very frequently puzzled in accounting for the real cause which has given rise to a specific and isolated case of infectious disease. Is it not reasonable to suppose that this mystery may be due, in certain cases, to the agency of bank notes? In his own experience a case some years ago came under his notice where a bank note was blamed as being the direct means of conveying infectious disease. In this case a young girl was recovering from scarlet fever, and took the first opportunity to communicate with her parents in the country, and while another inmate of the house was writing the letter the girl was absent-mindedly fingering a paper note which was enclosed in that letter. A few days after receipt of the note her sister took scarlet fever, which was not at that time anywhere in or near the locality. He had no doubt that similar instances could be cited by others. It appears that there is no proper or uniform system among the Scotch banks whereby these filthy notes can be recalled or taken out of circulation.

The present system seems to be to leave this to the discretion of the teller or some other bank official to retain such notes as he considers to be too dirty. He was afraid, however, that this duty is rather tardily done, as the production of new notes entails a little expense to the banks concerned; but surely the enormous dividends earned by our Scotch banks can well afford to let the public have clean notes, at all events in the absence of gold. No doubt when new notes are first issued they have something like an impervious gloss or sheen, which somewhat helps to prevent the ready lodgment of infected microbes. It was therefore obvious that the more frequently bank notes are called up the less danger there is to the public. Would it not be advisable that banks should call up at stated periods all notes, and retain such of them as they consider suitable for re-circulation, but seize and destroy all crumpled, soiled, or dirty ones, or those that are likely very shortly to become so? Any member of the public, however, has the right of demanding and obtaining payment in either gold or silver, which possibly may not be absolutely safe, yet certainly is safer than the filthy notes referred to.

National Health Society.

OFFICIAL TRANSACTIONS.

The annual general meeting of the Society will be held at 53, Berners-street, on Wednesday, April 24th, at 5.15 p.m. All members of the Society are invited to attend this meeting, when the report for 1900 will be read.

Suffolk.—Forty-eight lectures were given by one of the Society's lady lecturers in this county during 1900. The subjects chosen were Health and Nursing, and the attendances, composed of women only, have been excellent. "Every available woman in the village" is often the report of the local secretary. The lecturer (Miss Morgan) is of opinion that lectures on these subjects should be limited to women, and that such nursing and health as is necessary for men should come under the heading of First Aid. Unfortunately in Suffolk the County Council does not see its way to granting fees for examinations, so that there are no classes or examinations in this county.

ASSOCIATION OF NATIONAL HEALTH WORKERS.

The Committee of the above are now making arrangements for their annual course of lectures, which will take place during the week commencing May 6th. Miss Alice Busk has kindly promised to lecture on "Women as Sanitary Inspectors," on Tuesday, May 7th, while on Thursday, May 9th, Dr. Squire will lecture on the "Open Air Treatment of Consumption." On Friday, May 10th, a lecture on "Vaccination" will be delivered by Edward J. Steegmann, M.B., D.P.H. Other arrangements will be announced later.

Sheriff-Principal Rutherford recently, in Edinburgh Sheriff Court, heard parties' claims for exemption from the proposed scheme of Midlothian County Council to extend Liberton drainage district and to unite it with the Gilmerton special drainage district. The Sheriff remitted to Mr. B. Hall Blyth, C.E., a report as to whether the estimate prepared by Messrs. Belfrage and Carfae, C.E., was correct, and whether the sum of £1000 allowed in it for compensation for surface and other damage was sufficient; whether there were any natural features in the district which were obstacles, and whether the extension of the Liberton district and its union with the Gilmerton special drainage district was expedient. Mr. Hall Blyth has reported favourably of the engineers' report, but states that in addition to the ground which is included in the scheme there should be added other grounds, which include the reservoir and filter beds of the Edinburgh and District Water Trust at Alnwickhill, as well as other portions belonging to Major Gordon Gilmour, Mr. John Welsh, Moredun, and others. At a sitting of the Court last week, agents for the appellants intimated that they acquiesced in Mr. Blyth's report, and withdrew further opposition to the Local Authority's resolution. Counsel for the Edinburgh and District Water Trust, however, objected to the report, and craved delay to enable them to lodge answers. The Sheriff made avizandum.

CORRESPONDENCE.

(*To the Editor of* THE SANITARY RECORD.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

TAR PAVING FOR FOOTPATHS.

SIR,—I send the following particulars of a tar path I laid last year, in the hope they may be of some service to "Assistant" (Query 2123). The path, containing 440 yards superficial, was laid along an avenue where it was considered unnecessary to have kerbing. The original gravel path was 7ft. wide, and the new path is 5ft., leaving 1ft. on each side. The path was excavated to a depth of 2in. in the middle and an extra 2in. at the edges to make them solid. No concrete was used underneath as the ground was sufficiently solid. A layer of tarred gravel 1½in. thick was laid first, and on this was the top coating of slag, chips, and tar. The following quantity of material was used:—

	£	s.	d.
Slag, 14 tons 12 cwt., at 6s.	4	7	7
20 loads of gravel at 2s. 6d.	2	10	0
20 barrels of tar at 6s.	6	0	0
6 loads of sand at 2s. 6d.		15	0
3 tons of coal at £1 5s.	3	15	0
Labourer, 63 days, at 3s.	9	9	0
Carting	1	0	0
Total	£27	16	9

The stuff was mixed in June and laid in September, and has not been affected by the frost. One part of the path was faced with deal sawdust as an experiment. This is more silent than the sand faced, but the dripping of the trees was unfavourable to the experiment. The creeping will take place if the material is laid too soon after it is mixed.

Yours faithfully,

Godmanchester. C. MAYFIELD.

PERSONAL.

MR. GEORGE GROCOTT has been appointed Town Clerk of Hackney.

MR. S. CLEGG, of Darwen, has been appointed Electricity Engineer for Lincoln.

MR. C. PETTIT, of Ipswich, has been appointed Engineer at the Derby Workhouse.

MR. R. W. MARSHALL has been appointed Inspector of Nuisances for the urban district of Uttoxeter.

MISS DRAPER has been appointed Resident Medical Officer of the new Isolation Hospital at Walthamstow.

DR. WHITTINGTON has been unanimously reappointed Medical Officer of Health for Neath for the next three years.

DR. JAMES LAURIE, Greenock, has been appointed Medical Officer of Greenock Prison, in room of Dr. J. R. Black, deceased.

THE salary of Dr. Dudfield, as Medical Officer of Health for Paddington, has been increased from £600 to £800 per annum.

MR. W. R. DAVIDGE has been appointed Assistant Surveyor under the Teddington Urban District Council, at a salary of £100 per annum.

MR. R. G. MARSH, Assistant Sanitary Inspector at Leeds, has been appointed to the important position of Sanitary Inspector at Cape Town, South Africa.

AT the last meeting of the Richmond (Surrey) Town Council, the salary of the Water Engineer was raised from £320 to £350 per annum. This officer has been in Richmond's service for over twenty-five years.

MR. J. RODERICK has been reappointed Inspector of Nuisances for Llandovery.

DR. MILLARD has been appointed Public Analyst for Burton, at a salary of £50 per annum.

DR. F. T. BOND has been reappointed Medical Officer of Health for the rural district of Chipping Sodbury.

THE salary of Dr. J. Howard Jones as Medical Officer of Health for Newport, has been increased to £500 per annum.

ON the recommendation of the Health Committee, the salary of the Inspector of Nuisances for Richmond (Surrey) has been advanced from £175 to £200 a year.

THE Local Government Board has sanctioned the reappointment of Dr. W. J. Smith as Medical Officer of Health for Lepton, and Mr. Ed. Sykes as Inspector of Nuisances.

THE salary of Mr. Nesfield, Inspector of Nuisances, Surbiton, has been increased from £150 to £200 per annum. He is also to advance £10 per year for the next five years.

MR. WILLIAM FRANCIS DEWEY has been appointed Town Clerk of Islington, at a salary of £1150 per year, together with his fees as Returning Officer and Deputy Returning Officer at elections.

MR. JNO. JONES, who holds the certificate of the Sanitary Inspectors' Examination Board, and who was lately Assistant Inspector at Bethnal Green, has been appointed Sanitary Inspector to the Jewish Board of Guardians.

WE understand that Dr. F. J. Waldo is one of the six selected candidates for the Medical Officership of the City of London. Dr. Waldo's qualifications should stand him in good stead, and go a long way towards ensuring him a position which he is eminently fitted to fill.

WE are informed that Dr. E. Gwynn, the Medical Officer of Health for Hampstead, has sent in his resignation of the office, which he has held for over twenty years, stating that, having regard to the additional duties which would devolve on him, he is not prepared to continue in office under the terms proposed by the Borough Council, which were an increase of his salary from £350 to £700 a year, with a promise that he should not undertake private work.

MR. JOHN SIMPSON, who was recently appointed Health Inspector at Brisbane, served his apprenticeship to the plumbing trade at Aberdeen. He acquired a full knowledge of the work in a practical sense, and afterwards becoming impressed with the importance of sanitary science in connection with his business, and set himself to the task of gaining a knowledge of the subject with so much zeal and success that he obtained the diploma of the Sanitary Institute of Great Britain, and the diploma of the Sanitary Association of Scotland, the Sanitary Science Diplomas of the Guilds of London also fell to him. He afterwards acted as assistant on the teaching staff of Gordon's College, Aberdeen, and was ultimately for three years in full charge, teaching practical and theoretical sanitation.

THE able article on "The Housing of the Working Classes in Scotland" in last week's issue was by Dr. William Robertson—not Robinson, as printed. Dr. Robertson was, at the time it was written, Medical Officer of Health for Paisley; he is now Medical Officer of Health for Leith.

WANTED.—Mr. S. Protheroe, Sanitary Inspector, City of Hereford, would be greatly obliged to any of our readers who would supply him with, or inform him where he can obtain, a copy of the Public Health Acts Amendment Act, 1890, Sec. 23, dealing with (1) keeping water-closets supplied with sufficient water for flushing, and (2) the paving of yards and open spaces in connection with dwelling-houses.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

I FANCY that the extended experience of surveyors with the working of the Private Street Works Act, 1892, tends to a strong condemnation of it in practice, and inimical to progress, and that they would gladly revert to the system of making up private streets under Sec. 150 of the Act of 1875 were it possible to do so. Unfortunately, however, when the Act of 1892 is once adopted in any district it cannot be repealed.

ONE or two instances which have come under my notice recently evidence strongly the imperfections of the Act. In one of these a Local Authority resolved to make up a street 40ft. wide, which had been laid out by the landowner, who had included in it a public footpath 6ft. wide, which had been repaired by the inhabitants at large. The usual notices having been served upon the abutting owners to make up the street, objection was taken by them, as provided for by Clause (*b*) of Sec. 7 of the Act, to the proposals on the ground that "part of the street was a highway repairable by the inhabitants at large," and on the hearing before the magistrates the latter gave their decision that the Council had failed to prove that the road was a street as defined by Sec. 5 of the Act, and "not a highway repairable by the inhabitants at large," and the Council had to charge the cost of making up the street to the rates.

SUCH an interpretation of the law, paradoxical as it may seem, is not unsupported by the Act, for it is absolutely silent as to what is to be done where an owner sustains an objection that part of the street was formerly a highway. Under Sec. 150 of the Act of 1875, the owners would have been liable to pay in respect of the entire street, including the old highway (or public footpath). But under the Act of 1892 he may, if he places his case in the hands of a skilful lawyer, entirely evade his responsibilities, and also the cost of making up a street laid out by him where a narrow strip of it was formerly a public footpath.

IN another case where an owner, who had what is commonly known as a long "flank frontage" on a street, objected to the Authority apportioning him at the same rate as other owners on the ground of "degree of benefit," the magistrates—with that facility for deciding in favour of landowners which is so general—adjudged that he should pay on a greatly reduced apportionment, and the balance had to be charged to the rest of the owners or to the rates. Such methods of adjudication are vexatious and inequitable, and serve to illustrate the "glorious" uncertainty of the law and the objectionable provisions of the Act, whereby magistrates have transferred to them power to decide upon technical and other questions which, under the Act of 1875, were left to the Local Authority to decide.

FREE public baths are not yet known in this country, but there are many advanced sanitarians who advocate their establishment, and it is probable that such will eventually be established. In fact, there appears to be no limit to the addition of municipal burdens, nor to the increase of rates, and it is difficult to foresee where and how a "halt" can be called. In America, the city of Buffalo runs a free public bath all the year round, which is used by thousands of men, women, and children, and is highly popular. Each bather is provided with a piece of soap and a clean towel free of charge. During the month of January 10,957 men, women, and children availed themselves of the free bath privilege. The baths are inexpensively constructed, and in this respect English municipalities might possibly copy their example, for there is almost invariably a tendency to undue elaboration and ornament in English buildings of this class. As soon as it can be shown that the provision of free public baths is a good investment from a health point of view, I venture to predict that English municipalities will provide them.

I HAVE alluded before this in my notes to what has appeared to be a reasonable demand for a revision of the Model Series of Building Bye-laws for rural districts, and suggested the substitution of some hard and incombustible material other than brick or stone to cheapen the cost of construction of workmen's cottages. There does not, however, appear to have been any acceptable substitute put forward. In addition to the representations of a conference of Local Authorities, the Royal Institute of British Architects have been also pressing the Local Government Board to relax the bye-laws.

As a result the Board has drawn up a modified code of regulations, which are now obtainable. These regulations are not such as will commend themselves to Local Authorities, and they have been framed, it is evident, to meet the complaints of the Royal Institute of British Architects, and not for the especial purpose of cheapening the cost of erection of cottages. In fact, the Local Government Board have made a complete surrender to the private architect and absolutely ignored Local Authorities and their officials, whose experience and advice, if sought, would have been of incalculable good.

ONE has the greatest respect for the Royal Institute of British Architects, but it is impossible to ignore the fact that they are not so disinterested as to be able to advise as to how the public interests and public health should be safeguarded. Moreover, professional architects are not able to control the erection of possibly more than 20 per cent. of buildings erected in the country. The remainder are erected without his supervision, and the builder is responsible to no one save the Local Authority, whose function is to ensure that the bye-laws—framed for the purpose of securing stability, the prevention of fires, and for purposes of health—are observed. The architects complain that the enforcement of bye-laws "is an unnecessary and vexatious infringement of the liberty of the individual subject." This is a thread-bare catch phrase which has done duty for centuries in regard to all laws in civilised countries, and is dear to the heart of others than architects, viz., jerry builders. I hope to revert to this subject in a succeeding issue. SENEX.

OBITUARY.

DR. P. ALEXANDER, WHITLEY.

DR. P. ALEXANDER, of South End, North Parade, Whitley, died somewhat suddenly at his residence, on the 9th inst. He was sixty-two years of age, and has for many years been Medical Officer of Health of the Whitley and Monkseaton Urban District Council. In fact, the deceased gentleman was the oldest medical practitioner in the district. His death was somewhat unexpected, as until the previous Sunday he was in his usual health, and was out on that day.

LAST Thursday Mr. F. H. Tullock held an inquiry on behalf of the Local Government Board, at Teddington, with regard to an application of the Council to borrow £920 for camp-shedding the river frontage of the sewage disposal works, £666 for works of public street improvements, and £600 for works of private street improvements.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

The Sanitary Record

AND

Journal of Sanitary and Municipal Engineering.

APRIL 18, 1901.

THE WEAR AND TEAR OF LIFE.

LAST Saturday the Registrar-General issued his report on the estimated population, and on the marriages, births, and deaths registered in England and Wales during the year 1899. To the outsider it may appear strange that fifteen months must elapse between the close of a year and the issue of such returns, but when we consider the immense labour involved in dissecting the reports sent in by the sub-registrars, it will soon be realised that the time occupied is by no means excessive. Each year, too, the report increases in bulk, and invariably the Registrar-General emphasises some feature which takes hold of the popular fancy. This is often enlarged upon by the leading journals of the day, sometimes to the exclusion of the more important lessons set forth by the returns. This year the popular feature is the fact that the marriage-rate is the highest in any year of the last quarter of the nineteenth century. It is exactly the same as was reported in 1876, viz., 16·5, and is 1·1 above the mean rate of the term of years 1889-98. A high marriage-rate is a healthy sign for any nation. It indicates the prosperity of the staple industries, for when trade is bad there is always less inclination to embark upon the responsibilities of marital relationships. It will be surprising, however, if this upward tendency was maintained in 1900. The great drain which the country sustained during that year of young men drafted to South Africa must have told against it, and when the next report is issued we fully expect to see a considerable reduction in the percentage of marriages.

But the portion of the report to which the student of health statistics naturally turns is that which gives the death-rate for the year, and here he is doomed to disappointment. True, a rate of 18·3 is an improvement on 22·7, that recorded in 1875, the year of the passing of the Public Health Act, but it is a long way from the attainment of the ideal the sanitarian has set before him. For years in this country we have been trying to combat disease and abolish unhealthy surroundings. Millions have been spent in improved methods for dealing with refuse of all kinds; sewerage works have multiplied all over the land, and science and mechanics have joined hands to aid in providing economical and efficient means for treating the sewage. Great attention has also been given to the water supply, more particularly to that of the great cities. "Purity and plenty" has been the motto, and the most important engineering works of the period have been those carried out to meet the demand for its fulfilment. Our heating and lighting arrangements have been revolutionised, and that in a manner supposed to be in the direction of improvement, and beneficial to health. In many other ways the ravages of disease have been circumvented, and yet in spite of it all the waste of human life still goes on, and the national death-rate is 33 per cent. higher than it should be. The truth is that the efforts of the sanitarian are constantly counteracted by the developments of modern life. The physical conditions may be perfect; but if the mental worry is constant and the rate of living ever at high pressure, humanity breaks down under the load, and what is saved on the one hand is squandered on the other. Health and comfort are sacrificed to personal aggrandisement. Rational and life-giving food is neglected, and useless luxuries and irritating stimulants are indulged in. Recreation, which truly recreates the system and makes good the waste caused by the day's labour, is voted slow; and men cry out for the intoxication and excitement of sport and gambling, with their attendant evils. These are the things which keep up the death-rate, and until our countrymen realise the folly of the artificial existence they are creating, no efforts of the health worker will

succeed in bringing it down to a proper standard. The man's home may be clean, its surroundings perfect; but if the mind is disorganised—either by a craze for riches, for fame, or by selfish indulgence—so surely will he fail to reach the allotted span of three score years and ten.

The Sanitary Needs of the Old Bailey.

We recently directed attention to the defective sanitary arrangements of certain of the Government offices, and we have no doubt that were inquiry to be pushed further it would be found that many of our public buildings require looking into. A writer from the Temple makes complaint of the condition of the Old Bailey, that historic Court in which so many famous criminal cases have been conducted; and he mentions at least two specific cases in which the insanitary conditions under which they have had to do their work have led to the breakdown of the judges. Mr. Justice Wills had an illness after sitting at the Old Bailey trying the Lake cases; and Lord Alverstone, after trying the Yarmouth murder case, was not fit for his duties for nearly a fortnight after. Report has it that the unhealthy condition of this Court has also been responsible for other cases of illness among those whose professional duty has compelled them to attend it, and if this is so, the sooner the matter is remedied the better. The atmosphere of a criminal Court is seldom as salubrious as it might be, and especially during the protracted sittings of a popular and sensational criminal trial, when the presence of large numbers of the "great unwashed" make the place fœtid and unwholesome to a degree. But even making allowance for these necessary evils, it is discreditable that in this twentieth century any public Court should be allowed to remain in such a condition as to imperil the health of the judges who have to preside.

The Small-pox Epidemic in Scotland.

The reports from Scotland of the progress of the small-pox epidemic show a very much improved state of matters. Isolated cases continue to occur in various parts of the country, but for the most part they are not serious; and as the Authorities are everywhere keenly on the alert, and as re-vaccination has largely been taken advantage of wherever there is a threatening danger, little apprehension is now felt. Most of the cases that occur in other towns or in the country are traceable to infection from Glasgow. Two cases have, for example, broken out in the barracks at Belfast, and in both cases the soldiers had recently been in Glasgow, one on duty and the other on furlough. In Glasgow itself, for the last two or three weeks, the decrease in the number of cases in hospital has been steadily progressive. The official bulletin at the close of the week showed 220 cases under treatment, as against 275 at the commencement of the week. There is a small party in the Town Council that has been endeavouring to hamper the Health Department during the crisis in an irritating manner, but fortunately, being in a hopeless minority, their efforts do not do much harm. One gentleman wished to make a grievance out of the alleged refusal of the use of the Corporation Halls to certain lecturers who had come to the city to lecture on small-pox and its proper mode of treatment—presumably to discredit vaccination. Another showed great anxiety to have the report of a Sub-committee, appointed a considerable time ago, to inquire into the relations between the officials of the Health Department in which there had been some friction. To this the Lord Provost's very sensible reply was, that the Committee considered that the present was not a suitable time for such an inquiry, in view of the existing state of the city's health, when nothing should be done to disturb the harmony of the Health Department. Lord Provost Chisholm must be congratulated on the firm line he has taken in dealing with such vexatious troubles no less than on the activity and wisdom he has displayed at the head of affairs throughout the outbreak.

A Question of Liability.

An interesting decision is reported from Kirkcudbrightshire, regarding the liability of a Local Authority for failure to remove to hospital a case of infectious disease after notification. The household in which the case occurred consisted of a Mr. Gordon, his wife, their four young children, and five servants. On the afternoon of 9th August last one of the servants was found to have developed diphtheria, and the case was at once notified by the family doctor to the Medical Officer of Maxwelltown. The doctor also saw the Sanitary Inspector, and told him that in his opinion the servant should at once be removed. The same evening the Sanitary Inspector informed the doctor that his Local Authority declined to remove the case, and thereupon Mr. Gordon had the girl removed to hospital himself. His expenses in connection with the removal and the subsequent treatment in hospital amounted to £6 6s. 6d., for reimbursement of which he made a claim on the Local Authority, the Town Council of Maxwelltown. The claim being repudiated, he raised an action for the amount, alleging that it was impossible to properly isolate the servant in his house, and that her immediate removal was necessary in the interest of the public health, and of the servant herself, and that he had been put to expenses through the failure of the Local Authority to fulfil the duty of removal imposed on them by the Public Health Act. Sec. 54 of the Act, which imposes this duty, does so in the case of any person suffering from an infectious disease, "who is without proper lodging or accommodation, or is so lodged that proper precautions cannot be taken for preventing the spread of the disease;" and in this case the Local Authority disputed Mr. Gordon's statements as to the impossibility of isolation in his house, or the necessity for removal. Whether these statements were well founded in fact or not does not appear, for the Sheriff disposed of the case on a technical ground without any inquiry into the facts. He

held that the first duty of the Local Authority was to investigate the case, and to satisfy themselves of the necessity for removal. If they made an honest and *bonâ fide* investigation, even though their decision might be wrong, they would be protected by Sec. 166 of the Act; and before an action of damages could lie against them, it would have to be averred that they had failed or refused to investigate at all, or had contented themselves with what was not a *bonâ fide* investigation, and so had been in fault. As Mr. Gordon had not made any such averment, but had merely averred the failure to remove, which was not sufficient, the Sheriff thought the action must be dismissed. One cannot help feeling, however, that the decision was not altogether satisfactory. Certain correspondence which had taken place between the parties and the Local Government Board was produced in Court, and expressly referred to by the Sheriff in his judgment, from which it appeared that no investigation in the ordinary sense of the word was made. The Medical Officer, the Sanitary Inspector, and certain members of the Local Authority seemed to have simply discussed the matter among themselves, and come to a resolution without making any special inquiry into the circumstances of the case. If that was so, it seems regrettable that the Sheriff should have thought no proof was necessary.

Sanitary Certificates of Health Resorts.

The seaside season will soon be upon us, and paterfamilias will be looking round in search of a suitable venue for the summer vacation. To such a one the all-important question of health should carry weight no less than picturesque surroundings. As a matter of fact, some of the most popular resorts from the latter standpoint leave much to be desired on the former head. Outwardly they seem right enough, but their stuffy, ill-ventilated apartment houses are a direct menace to the healths of those who are destined to be immersed therein, and to this fact the Local Authorities are in many instances wilfully blind. In this respect Eastbourne furnishes a notable exception. This truly queen of Southern resorts possesses a system of granting sanitary certificates which practically ensures the visitor against any risk. What Eastbourne has done it is perfectly open for every health resort to do. The slight trouble entailed will be repaid many times over by the feeling of security that such a plan gives, and the corresponding increase in the influx of visitors during the season. Of course there is always a certain class of people who, through carelessness perhaps more than ignorance, affects to ignore this question altogether. It is the duty of the Sanitary Authorities to protect these. With such an excellent example before them there should be no excuse for neglect or procrastination. However picturesque or favoured by Nature a health resort may be, it ceases to become such in reality when its hotels, boarding-houses, and apartments are left free to disseminate disease by the indifference of those upon whom the bounden duty of protecting those who come there in search of health devolves.

Sanitary Inspectors' Associations.

LONDON.

An ordinary meeting of the members of the Sanitary Inspectors' Association was held on Saturday at Carpenters' Hall, London Wall, E.C. Mr. W. West (Walthamstow) occupied the chair, and those present included Messrs. H. Alexander, I. Young, Styles, A. Ashdown, A. G. Duck, Henley, S. C. Legg, Lear, Nurcombe, E. Tidman, C.E., the Hon. Secretary, &c.

Mr. T. G. Dee, the hon. treasurer of the Association, opened a discussion on the "Present Position of the Sanitary Inspector." He said that the Public Health (London) Act, 1891, would probably be the basis of alterations of law when the position as set out in the Public Health Act, 1875, is varied. He contended that primarily the tenure is not weak nor the salary often poor, nor sanitation impeded because of the defects in the law. The tenure and salary under Section 108 of the 1891 Act is that which the Local Government Board choose to make it, subject only to the limitation that they can only do that which 4 and 5 William IV., cap. 76, Section 46, gives them power to do in the case of a District Medical Officer. This provided that the officer should hold his appointment until he shall die, or resign, or be proved to be insane. Such a tenure as this and a proper salary surely was all that a Sanitary Inspector need ask, and it could be obtained without further legislation, but they had only been accorded by Art. 10 of the General Order of the Local Government Board of the 8th December, 1891, the position that every Sanitary Inspector shall continue to hold office for such period as the Sanitary Authority may, subject to their approval, determine at the time of his appointment, or until he die or resign, or be removed by such Authority, or by the Local Government Board, or be proved to be insane. Art. 14 of the same Order decided the amount of salary to be such as may be approved by the Local Government Board, no power being given to that Board to direct what salary shall be paid. With respect to the legal powers of Sanitary Inspectors to deal with nuisances, he was of opinion that all or almost all he requires is to be found in the law as set out in the Public Health (London) Act, 1891. The question therefore rose, viz., whether or not the administration is defective? It might be accepted that certainly the tenure of office might be much improved if the Local Government Board could be induced to administer their powers in as liberal a spirit as has been done with district Medical Officers of Poor Law Unions. He therefore claimed that the present administration of the law is detrimental to the true interests of the public by leaving the Sanitary Inspector's position liable to be taken from him in consequence of a due fulfilment of his duties when that is against the personal interest of his direct employers. The Local Sanitary Authority were at times very diffident in enforcing all the powers they possessed, the law was enormously strong and very clear, yet they all knew that it is frequently not fully administered. What an unsatisfactory position for the Sanitary Inspector who by the direct order of the Local Government Board reports such breaches and then finds that he is unable to do anything, strong law notwithstanding. The varieties of methods adopted by the different authorities in dealing with the duties of Sanitary Inspectors prevents full fruition of his work. Then, again, administration frequently failed because of the

nominal fines inflicted, in his discretion, by the magistrate. Dealing with the personal aspect of the question, Mr. Dee said egoism was useful to the Inspector in his work, as it tended to make him faithful to his duties, but the very power Sanitary Inspectors possessed as officials had a strong tendency to so foster this spirit of egoism as to make them almost forget that it is the position which the law has made which carries the power, and begin to think that it is to themselves and not to their office that the expected deference is paid. When personality gained the upper hand of a humble desire that their office should be magnified, they as individuals commenced to deteriorate, and their work suffered by the consequent loss of influence on others, their judgment is weakened, and they were unable to make due allowance for an opposite opinion to their own. He urged them to endeavour to leave the position of the workmen and his foreman in manners, dress, and speech, and to endeavour to rise to the professional status. Until they worked together in this way Sanitary Inspectors would not advance in the eyes of the public and their representatives on Sanitary Authorities as a body of professional men. They should be able to take up one or other of the undoubted hardships that Sanitary Inspectors meet with, and obtain wide publicity for their njustices. In conclusion, Mr. Dee urged that they must press the Local Government Board to give Sanitary Inspectors a better tenure of office; they must urge and educate the public to send the very best men as their representatives on Sanitary Authorities—men who had no axes, political or otherwise, to grind; magistrates must be urged to see eye to eye with sanitarians when the Inspectors were compelled to bring bad cases before them; but he believed that the elevation of their profession as a whole would do more than anything to bring about the legitimate ends they all had in view.

Discussion followed, and a hearty vote of thanks was accorded to Mr. Dee, and on the motion of Mr. I. Young, it was further resolved to refer to the Council of the Association the question of considering the advisability of making representations to the Local Government Board as to amending the Order of 1891, so as to secure the position of the Sanitary Inspector, as provided by the Public Health (London) Act, 1891.

A vote of thanks was accorded to Mr. West for his effort in arranging an interesting visit to the various municipal undertakings of the Walthamstow Council.

MR. HOOLEY AS A SANITARIAN.

Having retired from active service in the field of finance, Mr. Hooley is devoting himself to the solution of sanitary problems. The housing of the rural poor has apparently found in Mr. Hooley a sturdy, practical exponent, for some cottages recently erected on his estates of Eltisley and Papworth have received high encomium from the Medical Officer of Health for the district. The cottages are built upon concrete foundations, they are large and commodious, and are most admirably fitted with all sanitary arrangements, and dry-earth self-acting closets are fixed for each cottage at some distance from the house. The water supply is ample. The cottages are mostly built in pairs.

Each cottage has its own water-butt for collecting the rain-water from the back part of each house, and there is for each two cottages a large underground cemented reservoir for receiving the rain-water from the other portions of the roof.

Each pair of cottages has also a well 20ft. deep, and is provided with a cast iron pump. The water afforded is somewhat brackish, as coming from the clay, but is free from vegetable or organic matter. There is a good garden for each house and ground at the back. The wells are situated in each case in the front gardens. These cottages are perfect models of cottages for the agricultural labourer.

Mr. Hooley has erected three pairs in Eltisley and six pairs in Papworth, making a total of eighteen tenements, and two other pairs are in course of erection, and the ground for several new pairs is staked out, added to which he has also built new schools of the most modern type for the village of Papworth.

It is Mr. Hooley's intention to build many more of these most desirable cottages upon his estates.

SEWAGE DISPOSAL IN INDIA.

Some interesting and successful experiments connected with the purification of liquid sewage and sullage water have been carried out in the Howrah municipality by Mr. A. Hale, M. Inst. S.E., superintendent, in charge of the Conservancy Department. The process employed is a combined biological and mechanical one, and the operations consist in passing the highly foul and offensive liquid through a specially designed primary filter constructed on the "Scott Moncrieff" principle, by which upward filtration is obtained and a secondary process of downward filtration through bacteria beds. The material contained in the primary filter is nothing more than pieces of coarse broken bricks, clinker, and cinders, arranged in alternate layers; and the sewage while passing slowly upwards through these substances is vigorously operated upon by numerous micro-organisms which attack and eliminate the putrescent suspensory matters contained in the sewage, and the effluent leaves the filter smelling strongly of sulphur, but otherwise practically free from solid organic or offensive substances. On leaving the primary filter, the effluent is led over a broad weir and into the bacteria beds, for final purification and oxidation before escaping into the outfall drains. The bacteria beds consist of layers of earth and fine cinders and are about 3ft. in depth, and the effluent filters slowly through, by percolation, emerging from the under drains; in colour a deep brown, and with still a slight odour of sulphur, which is said to entirely disappear as the effluent flows away. The filters and bacteria beds, besides being inexpensive to make, are almost continuous in their action, and require no skilled supervision, when once set going, to maintain the best results; the only precaution necessary is to prevent hard foreign substances, such as stones and sticks, being introduced into the former, and to scrape off the thick scum which forms on the surface of the bacteria beds every week or so.

A letter has been sent by Mr. Noel T. Kershaw, Assistant Secretary of the Local Government Board, to the Clerks of the Authorities interested in the recent application by Stockport to extend its boundaries. In it he informs them that he is directed to state that they have received the report made by their Inspector, Mr. Tulloch, after the inquiry held by him with reference to the representation of the Town Council of Stockport in favour of an alteration of the boundaries of the borough. The Board, having carefully considered the evidence given at the inquiry, together with the report of their Inspector, have come to the conclusion that the facts are such as to warrant some extension of the borough, and they propose to issue a Provisional Order for including within its limits the whole of the urban district of Reddish, part of the urban districts of Bredbury and Romiley, Cheadle, and Gatley, and Heaton Norris, part of the urban district of Hazel Grove and Bramhall, and a part of the parish of Brinnington. The boundaries of the areas to be added to the borough are defined by a hard red line on a map which has been forwarded to the Town Clerk. The result of the extension will be that the acreage of the borough will be increased from 2200 to 5600, and the population from 82,000 to about 100,000.

Public Works.

SEWERAGE.

THE Hay Council, N.S.W., has accepted the Government offer to sewer the town at a cost of £17,000.

COLONEL W. L. COKE has held an inquiry at Erdington into an application of the Urban District Council for sanction to borrow £8000 for works of sewerage and sewage disposal.

A SPECIAL meeting of the Exmouth District Council was held last week, when the Council's seal was affixed to the Public Works Loan Board to deliver to Mr. Darke a certificate for £5000, being the fifth instalment of the loan of £33,150 for works of sewerage.

THE Local Government Board has sanctioned the proposal of the Barrow Rural District Council to borrow £1945 for the purpose of sewerage and sewage disposal at Newtown Linford, also the borrowing of £7000 for the execution of sewerage and sewage disposal works at Woodhouse Eaves.

THE Secretary for Scotland has intimated a general approval of the scheme prepared by Mr. W. A. Carter, C.E., for the purification of Dumfries sewage. Works for bacterial filtration are to be erected in the garden at Castledykes, a residential property which the Town Council has bought for the purpose.

MR. M. K. NORTH, an Inspector of the Local Government Board, attended at Fletton last week to inquire into the application of the Norman Cross District Council for power to borrow an additional £6500 to complete the drainage scheme. After hearing evidence, examining the plans, and visiting the works, there being no opposition, the inquiry was closed.

COLONEL A. C. SMITH, C.E., of the Local Government Board, held an inquiry at Little Hulton into the application of the District Council for consent to deviations in the sewerage scheme, in respect of which a loan of £13,000 was sanctioned seventeen years ago. Evidence was tendered in support of the application, after which the Ellenbrook sewage works were visited.

COLONEL MARSH held an inquiry at Egremont last week, into the merits of an application made by the Wallasey Urban District Council for permission to borrow £12,500 for the purposes of extending the electric lighting system of the district, £5860 for works of sewerage, £5800 for provision of public conveniences at New Brighton, and £3000 for purposes of street improvements.

AT a recent meeting of the Sewerage Committe of Aberdeen Town Council an application was received from Messrs. Richards, Limited, for leave to run off the surface water from the proposed new works at the south side of the bridge of Dee, to join the river east of the bridge. As this would mean something like 500,000 gallons a day, the Committee deferred the matter for inquiries to be made.

THE Withington Urban District Council has accepted the Main Drainage Committee's recommendation that the tenders of Messrs. Nowell, of London, for contract No. 3 for the sum of £22,964, and for contract No. 4 for £21,612 be accepted. The former related to the construction of new main outfall sewers from the sewage farm to a point near Hough End Hall, Nell-lane, Chorlton-cum-Hardy, and the other to the construction of new main outfall sewers from a point in Withington-road, Whalley Range, to near Hough End Hall, and forward to a point near the corner of Burton-road and Lapwing-lane, West Didsbury.

ACCORDING to a recent report, says the *Engineer*, the expectations of the constructors of the Chicago Drainage Canal, which was made for carrying away the sewage of the city, containing over a million inhabitants, have been realised. The idea of pouring the sewage of a large city, amounting to 50,000 cubic feet a minute, into an open channel, and allowing it to flow away without any attempt at purification, was startling. It appears, after eight months' working, none of the actions threatened by the towns bordering on the river below Chicago have been commenced, and it is reported by competent authorities that the water in the canal is free from objectionable features.

SANCTION has been obtained to the borrowing of £17,423 for sewerage works, and £510 for pumps and machinery at Altrincham.

AT the last monthly meeting of the Colwyn Bay District Council it was reported that the new drainage scheme was estimated to cost £59,978. The report, plans, and estimates have been submitted to Mr. Baldwin Latham for expert opinion thereon. The Finance Committee reported that from a summary of receipts and expenditure for the financial year it appeared that the net income had amounted to £14,430, an increase on the estimate of £430, and the net expenditure had reached £14,160, an excess over the estimate of £460. It appeared that a sum of £2,615 was due from loans, and that £1,912 was unexpended on account of loans. The net balance due to treasurer on the 31st ult. was £681.

WATER.

IT has now been definitely stated that further opposition to the Prestatyn Water Bill will be raised in the House of Commons on behalf of Mrs. Rowley Conwy.

THE Town Council of Denny has resolved to instruct its Engineer, Mr. Frew, Glasgow, to proceed with the erection of a supplementary reservoir in accordance with plans prepared, and to issue schedules to contractors with a view to have the work in hand as early as possible.

A MEETING has been held at Ilford for the purpose of passing a resolution of owners and ratepayers of the urban district to give consent to the Council opposing a Bill which is being promoted in the present session of Parliament by the South Essex Waterworks Company, to construct further works and extend their limits of supply, and for other purposes.

AT its last monthly meeting the Kirkintilloch Town Council fixed the contract for the construction of a new reservoir to contain 40 million gallons. The work was given to Mr. James Miller, contractor, Kirkintilloch, at the contract price of £19,937. Mr. Miller is presently engaged at the Duntocher and Dalmuir waterworks, and it is expected this new work will be three years in progress.

DR. W. H. WEBB, in his annual report on the health of the Kingsbridge district, referred to the need of a more adequate water supply for the town, and strongly advised the Council to adopt the Infectious Diseases Prevention Act of 1890, whereby more adequate powers were vested for suppressing the spread of all dangerous infectious diseases likely to be disseminated by the sale of infected milk, &c.

COLONEL LOCKWOOD, M.P., presiding at the half-yearly meeting of the East London Waterworks Company, expressed satisfaction at the rejection of the Purchase Bill of the London County Council, questioned the soundness of the assumption that the acquisition of the water undertakings was really desired by the ratepayers, and declared that the political capital and gross misrepresentations that were made at the County Council elections out of the proposed new regulations would be a disgrace to all concerned.

AT the meeting of the Wolverhampton Town Council on Monday the Water Committee submitted a report with regard to the water supply for the borough. It states that the scheme for augmenting the supply by establishing new works at Worfield having been rejected by Parliament, it has become desirable that a previous suggestion for filtering the brook water at Cosford should be carried into effect. The Engineer is of opinion that the best way of treating the water is to adopt mechanical filters of the gravity type, which, whilst possessing similar features to ordinary filter beds, will treat large volumes of water in a very little space, without requiring constant attention or the employment of a large staff to renew and wash the filter media. Mechanical filters of the gravity type perform their work in the same manner as ordinary filter beds, but, instead of relying on zoogloea for arresting and collecting bacteria, a solution of sulphate of alumina is used to form the gelatinous film on the face of the filtering media. The makers of this particular plant are prepared to guarantee that the filtered water shall be bright, clear, and practically free from turbidity and matter in suspension and colour. The cost of the work is estimated at £3500, and the Committee recommends that it be empowered to expend this sum in providing such a plant.

Messrs. R. Laidlaw and Sons, Glasgow, have secured the supplying of the water mains for the Edinburgh and District Water Trustees at a cost of £2530.

The fortnightly statement of the Edinburgh and District Water Trust shows that the delivery in Edinburgh per day was 16,586,000 gallons, equal to 39·49 gallons per head each day. The total quantity of water in the reservoirs at April 9th showed an increase of 3,087,000 gallons compared with March 26th. The rainfall at Glencorse from January 1st to date was 8·82in., against 11·90in. last year. At Gladhouse it was 7·24in., as compared with 10·89in. last year.

Last week the formal opening of Lochcote Waterworks, the property of Bo'ness Town Council, took place at Lochcote House. A large number of representatives of the public bodies, the engineers and contractors, along with a number of ladies, were present at the opening ceremony. After the water was turned on the company repaired to Lochcote House, where dinner was served, and a large toast list entered into. The capacity of the new waterworks is 200,000,000 gallons, and represents a total cost of £29,105. Messrs. Leslie and Reid, Edinburgh, were the engineers who planned the work, and Messrs. Peattie contracted.

A very satisfactory report as to the state of the reservoirs was made to the Manchester Waterworks Committee last week. It was stated that since April 1st there has been a rainfall of 1¾in. at Longdendale, which is about ½in. more than during the same period last year. This has largely augmented the stock, and the reservoirs are full. There is at present a supply of 5153 million gallons, against 4578 million gallons last year. This gives 126 days' supply, against 112 last year, or, with the yield of the springs, a supply sufficient for 160 days. At Longdendale a good deal of water is running to waste, owing to conditions which in course of time will be remedied, and at Thirlmere the water is running over the sill. The Waterworks Committee feels that there need be no fear of a scarcity of water during the coming summer.

LIGHTING.

The Malvern Urban District Council proposes to spend £13,000 in completing the gasworks at Malvern Link.

The Colchester Corporation has decided to borrow £3900 for the purpose of extending its electric lighting station.

The capital of the Andover Gas Company is to be increased from £8000 to £14,000, to enlarge the works to cope with the growing needs of the town.

The Hull Town Council has decided to spend a further £17,000 in works of electric lighting, and £900 in constructing an underground lavatory in the Market Place.

At a recent meeting of the Electric Lighting Committee of Leith Town Council it was resolved to recommend the Council to reduce the price of electric energy for lighting purposes from 5d. to 4d. per unit, there being now about 280 consumers connected with the mains, or an equivalent of 25,830 eight-candle-power lamps.

At the meeting of the members of the Accrington and District Gas and Water Board, held last week, the Board's seal was affixed to two loans of £1000 each. Tenders for six months' supply of tubes and fittings were accepted. The Clerk was instructed to apply to the Local Government Board for further borrowing powers for the laying of water mains for a period of three years.

At the last monthly meeting of the Morecambe Urban District Council, the Chairman of the Gas Committee congratulated the town on coming into possession of its gasworks. Although some had said the purchase price of £141,000 was high, he noticed Osset had just paid a bigger sum for its works. The former Committee had rather muddled the negotiations for a loan, but he was glad to say the Committee of which he was Chairman had, since December, not only completed the purchase, but saved the town £1500 in procuration fees, an amount which would have had to be paid if the money had been secured through London agents. The Committee hoped to introduce the meter system of prepayment for lighting and cooking purposes, and it did not anticipate the acquisition of the undertaking would greatly affect the rates.

A Local Government Board inquiry has been held into the application of the Peterborough Town Council to borrow £12,200 for electric lighting purposes.

The Local Government Board has written the Wolverhampton Town Council sanctioning the borrowing of £59,942 for the purposes of supplying electricity.

Intimation has been received at Nuneaton that the Board of Trade proposes to grant, subject to certain modifications and amendments, the provisional order necessary for the extension of the undertaking of the Nuneaton Gas Company. The application of the company was to raise additional capital to the extent of £50,000, but the commissioner who held the inquiry on behalf of the Board of Trade suggests that the sum be £40,000.

Mr. W. S. Johnson, of Sheffield, has been appointed Clerk of Works in connection with the electricity works of the Heywood (Lancs) Corporation, at a salary of £2 per week. These works are to be established at a cost of £15,000. The Local Government Board has declined to sanction a loan of about £2000 to enable the Heywood Corporation to wire consumers' premises free of charge on the ground that the granting of sanction for such a loan would establish an undesirable precedent.

The Skipton Urban Council is carrying out extensions of the gasworks acquired for the town a year ago. The latest project is to convert the ammoniacal liquor into sulphate of ammonia, and acting upon the advice of its consulting engineer (Mr. Porter, of Elland), the Council has sanctioned the scheme, which, for the remarkably modest investment of £450, is calculated to bring in the handsome return of over £200 per year. The Council has also decided to erect a new governor house. On the first year's working there is a small profit, notwithstanding the inflated price of coal.

At a crowded meeting of Winsford property owners and ratepayers last week, the Urban Council asked for sanction to deposit a late Bill in Parliament to empower it to manufacture and supply gas and provide for the transfer to the Council of the local gas undertaking. Some time ago the Council resolved to purchase the works for nearly £16,000, the price fixed by the arbitrator. The Local Government Board, however, refused to sanction the loan unless a provisional order or Parliamentary Bill was obtained. After a lengthy discussion the ratepayers decided by an overwhelming majority to withold consent. A poll was demanded, and will take place early in May.

Greenock gas consumption continues to decrease. Since July 1st last—a period of nine months—the decrease has been no less than 3,340,900 cubic feet compared with the previous year. Last month the gas consumed was less by 61,700 cubic feet than in the March of 1900. It is noteworthy that in the nine months referred to, while the gas consumed has shown such a shrinkage, only 260 tons less coal were used at the works. The popularity of electric light is the principal cause of the reduction in the consumpt. Greenock Police Board, however, intends to extend the gasworks shortly, and to improve the methods of production, at an estimated cost of nearly £50,000. Last week the Board decided to ask powers in its new Provisional Order to borrow £100,000 for this purpose.

GENERAL.

The Ashford Urban District Council is expecting the sanction of the Local Government Board for the purchase of a site for an infectious diseases hospital.

A Local Government Board inquiry has been held at Derby with reference to the application of the Town Council for sanction to borrow £1175 for the purpose of street improvement.

A Local Government Board inquiry has been held at Yarmouth with reference to the application of the Town Council for sanction to borrow £7500 for the improvement of the foreshore at Gorleston, and £2580 for works of paving.

The Electric Lighting and Traction Committee of the Batley Corporation has received from its Engineer (Mr. Clirehugh) an estimate of the cost of laying and equipping the tramways authorised by the Order obtained last year. The estimate is over £50,000, exclusive of the electricity generating station and plant.

A NEW joint isolation hospital, which has been built by the Romford Urban and Rural District Councils at a cost of over £10,000, has been opened at Rush Green, Dagenham, Essex.

THE Rochdale Town Council has decided to proceed at once with the proposed tramways extension, and has instructed the Borough Surveyor to carry out the same by direct labour.

THE Local Government Board has consented to the raising of money by the Southend Town Council for the housing scheme, and the Borough Surveyor has been instructed to prepare details, with a view to the invitation of tenders.

AT a recent meeting of the Dewsbury Joint Hospital Board a call for £3000 was made upon the several townships, the money to be devoted to the erection of the hospital at Mitchell Laithes, of which a considerable portion is already constructed.

THE formal opening of the Stockton refuse destructor, which has been erected by Messrs. Horsfall and Co. for the Stockton Corporation in the Corporation Yard, Richmond-street, at an estimated cost of £3091, took place last Thursday. The main buildings contain two Horsfall patent-type cells, each of which is capable of burning ten tons of refuse in every twenty-four hours.

THE Hampstead Borough Council having recently adopted Part III. of the Housing of the Working Classes Act, 1890, has instructed its Public Health Committee to make full inquiry into the nature and extent of overcrowding in the most thickly-populated streets of the borough. In order that this may be done effectually several additional sanitary inspectors have been appointed, including Miss A. Gough.

THE Local Government Board has now approved of the terms of agreement for the proposed Central Combination Hospital for infectious diseases to be erected at Netherclough for the use of patients in the Lockerbie district and the burghs of Lockerbie, Moffat, and Lochmaben. In addition to the joint hospital the agreement approved of by the Local Government Board provides for a common hospital for the use of persons within the limits of the combination who may be suffering from small-pox, as also a sectional hospital, or hospitals, for patients who cannot be removed to the central hospital.

THE Chelsea Borough Council has this week considered a proposal to erect new public baths on a site acquired by the late Vestry adjoining the Town Hall. The scheme includes the provision of about 100 private baths and three swimming baths, the largest being 100ft. by 35ft.; whilst one, 60ft. by 25ft., will be reserved for ladies, for whom about fifty private baths will also be provided. The cost of carrying out the scheme, exclusive of the price of the site, is estimated at between £60,000 and £70,000. The Public Baths Committee reported that a scheme for public wash-houses can be carried out on land adjacent to the site, but that additional land would be required, and the cost would be from £8000 to £10,000. It is not contemplated that action on the latter proposal shall be taken for at least another twelve months.

AT the last meeting of the Sanitary Committee of the Dundee Town Council reports were submitted relative to the employment of female Sanitary Inspectors in other cities. It was stated that in Liverpool there were eight female Sanitary Inspectors. Their duties consisted chiefly of house-to-house visitation of the dwellings of the poor, the object being to induce cleanliness and an observance of the laws of sanitation in compliance with the requirements of the Local Authority, and of seeing that the Factory and Workshops Acts, as applicable to premises wherein females are employed, were duly attended to. The salaries of these officials ranged from 30s. to 35s. per week, and it was reported by the Medical Officer of Liverpool that their services were of great value. In Manchester it was reported that there were two female Inspectors, in Glasgow seven, and in Greenock one at a salary of £50. In each of these cases it was stated that the work they performed was highly prized by the Local Authorities in question. The information contained in the reports referred to was remitted to the Medical Officer and the Sanitary Inspector to consider and report to the Committee, which will thereupon formulate such recommendations as they may consider judicious for the determination of the Town Council.

THE Liverpool Health Committee proposes to ask the City Council to place at its disposal a sum not exceeding £150 for the purpose of entertaining the members of the Congress of Sanitary Inspectors when the latter visit Liverpool.

THIS week Newcastle-upon-Tyne is passing through a curious experience. The lease of the tramways to the Newcastle Tramways Company expired on Saturday, and the tramcars ceased running throughout the city. The Corporation is installing a service of electric tramways on the overhead trolley system, but it will be at least six months before this is complete. They have endeavoured to keep the existing system going while constructing the new one, but found that it delayed the work. It would seem that the public have no alternative but to put up with the inconvenience thus caused.

LAW CASES.

Lodging-house Inspector's Unsuccessful Action.

AT Swinford Quarter Sessions last week, before Judge Deane, the case of Sub-Sanitary Officer Hurst came on for hearing. This was an action for £50 against the Swinford Rural District Council, salary alleged to be due to plaintiff for his services as Common Lodging-house Inspector. Messrs. M. J. Kelly and J. P. Mannion for plaintiff; Messrs. P. O'Connor and John Garvey for the District Council.

The plaintiff gave evidence that he was appointed in 1888 by the Swinford Board of Guardians as Sub-Sanitary Officer, and during that time he acted as Inspector of Common Lodging-houses. Latterly the duties in that respect have increased, owing to the energy and vigilance of Sir Achison McCullagh, and plaintiff now claimed £50 for the extra work.

Mr. GARVEY contended that the plaintiff had no case, inasmuch as he was bound as Sub-Sanitary Officer to inspect and report on common lodging-houses and everything of an unsanitary nature, and nothing of a more unsanitary nature could come under his notice than an overcrowded lodging-house; hence he was bound to do these duties, and in support of his contention quoted Sections 11 and 78 of the Public Health Act, from which it would be seen that the position of Sub-Sanitary Officer and Inspector of Common Lodging-houses were not two distinct offices.

Mr. KELLY argued *contra*, and stated that the salaries of Inspectors of Common Lodging-houses had been fixed in three unions.

Mr. GARVEY challenged this statement, and said that the present case was the first of its kind tried in Ireland.

His HONOUR concurred with Mr. Garvey, and held that nothing could be more unsanitary than an overcrowded lodging-house, and it was once the origin of the greatest outbreak of fever that ever swept over Europe. The action was unfounded and preposterous, and he would dismiss it with full costs and expenses.

The Liabilities of House Agents.

AT the Loughborough Petty Sessions, before Rev. R. Burton and other magistrates, William Armstrong, house agent, Loughborough, was summoned at the instance of the Loughborough Corporation for that he, being the owner of a house in Rectory-place, failed to comply with an order of the Urban Sanitary Authority requiring him to provide proper and sufficient down-spouts and cross-gutters, so that the rain water should not flow over the footpath.

The Town Clerk, Mr. H. Perkins, prosecuted, and Mr. H. Deane defended.

The TOWN CLERK said the original Act under which the proceedings were instituted was the Town Improvements Clauses Act, 1847, which was embodied in the Public Health Act, 1875.

Mr. DEANE said there was no dispute as to the spouts and gutters being required. But Mr. Armstrong was not the

owner. His firm were the collectors of the rents, and they had been distinctly told by the landlord not to do the work, and if they did they could not recover.

Mr. PERKINS contended that under the Public Health Act definition of owner the Authority were empowered to proceed against the receiver of rents. It might be very hard on Mr. Armstrong if the actual owners gave him orders not to do the work, in defiance of the Authority, but that was so much the worse for him, and it did not relieve the Authority of their duty in seeing that these down-spouts and cross-gutters were properly fixed. These proceedings had arisen from the complaint of persons resident in the neighbourhood. Similar orders were served on adjoining owners, and had been complied with, and the Authority felt they could not allow this matter to pass. Every opportunity had been given to Mr. Armstrong to get the work done, and he had explained his position, to which he (the Town Clerk) had replied that he would be justified in doing the work himself, and deducting it from the rent.

Ralph Lord, Sanitary Inspector under the Corporation, proved the necessity for the work, and the notices issued.—Cross examined: He had not ascertained that Mr. Wm. Armstrong himself had never received a penny of this rent, but knew he was a member of the firm of W. and F. Armstrong.

Mr. PERKINS also gave evidence, stating that Mr. Armstrong had explained his position to him, and that Mr. Rickard, one of the trustees of the property, declined to allow him to carry out the work ordered by the Authority. Witness told him that in his opinion he could do the work himself and deduct the cost from the rents.

In cross-examination, the TOWN CLERK said he contended that for the purpose of this Act the rent collector was the owner against whom the Authority ought to proceed. He did not consider they ought to proceed against Mr. Rickard, for he would say, as Mr. Armstrong did, that he did not keep the rent, but handed it on to someone else. His opinion was that an agent was justified in doing what was necessary to save himself from the action of the law, and he did not think any principal could compel his agent to act contrary to the law. Witness had seen the telegram received that morning from Mr. Rickard stating that if the summons was withdrawn he would undertake to have the work done at once. The proceedings were not pressed in order to see if all agents could be made responsible, and so the Authority could avoid having to find out the owners, and proceed against them. He considered it was too late in the day to make this offer, and he could not get instructions from his Committee to withdraw the case.

Mr. DEANE said the Corporation had the option of proceeding against the actual owner, the occupier or the agent, and they had chosen to go against the one person who, if he spent the money in doing the work had no power to get it back, because he would be acting outside his instructions. An important point was raised by this case, important to Mr. Armstrong and other rent collectors, whether the Corporation was right in the contention that they might drop the occupier and actual owner and go against the rent collector. A further point was that Mr. Armstrong was only a receiver of rents and was not therefore an agent. The case was a distinct hardship on Mr. Armstrong, for he stood between somebody and the deep sea. On the one hand he was told if he did the work he would not be allowed for it, and on the other he was summoned for not doing it.

Wm. Armstrong, the defendant, went into the box, and stated that personally he had had nothing to do with these houses, and had never received any of the rents, his son having done that. His firm had nothing to do but receive the rent and hand it over, and they were not the agents for the property, but simply the rent collectors. If he had been free he would have had this work done, but he was specially instructed not to.—Cross-examined: If one of the houses became empty, they would do their best to let it again, and they would accept notices from the tenants.

The Bench having consulted, the CHAIRMAN said they had come to the conclusion that Mr. Armstrong was the technical owner of the property, and they would therefore make the order for the work to be done.

Mr. PERKINS said it was a case for a penalty for non-compliance with the order already made by the Corporation.

The Bench then imposed a fine of one halfpenny a day for the 28 days, the period of non-compliance alleged in the summons.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2162.—SEWER DISCHARGING IN TIDAL RIVER: CONSENT OF BOARD OF TRADE REQUIRED.—"Surveyor" writes:—"My Council have recently let a contract for making a sanitary pipe sewer which has its outlet into a tidal river, and have received a request from the Board of Trade and also from the Commissioners of the river for plans and sections of the work, showing high and low-water mark, and any works which are intended to be laid down for the purification of the sewage before discharging it into the river. They also ask to be informed 'how many gallons per day' of sewage we intend to so discharge. Can either or both of them demand legally to be supplied with any or all of these particulars and plans? It is ordinary household sewage from a locality where there are very few water-closets. I had an impression that a District Council could without let or hindrance discharge ordinary sewage into any tidal river which the Local Government Board had not declared to be a stream, and this is the position of ours. Can you please enlighten me on this point also?"

Answer.—The Local Authority must comply with the requirements of the Board of Trade and River Commissioners, and submit plans to them as required. See Sec. 327 of the Public Health Act, 1875. The consent of these bodies must be obtained to the plans before proceeding with the work.

2163.—COMPENSATION FOR LAYING SEWER: ARBITRATION.—"Plymouth" writes:—"My Council have recently had a pipe sewer laid through agricultural land, the work being done by a contractor who was required both by signed agreement and specification to pay all surface damage. The claim for the surface damage was £50 for 822 yards of 9in. sewer through land let for 10s. per acre. The claim was made to the Council, as the farmer would not deal with the contractor. The contractor offered to pay £10 either direct or through the Council, this the farmer would not accept, and demanded of the Council arbitration. This was agreed to by the Council, and the award was £37 and expenses. The contractor's agreement entitled him to monthly payments on work done, less 10 per cent., which he was to have after the work had been three months finished. Six months and more have now elapsed, but the Council still retain sufficient of the contractor's cash to pay the claim for damages and expenses, and intend to do so. What I should like to know is: (1) Can the Council detain the contractor's money beyond time mentioned in agreement, in view of his not settling such claims as the foregoing? (2) Can they under the above circumstances legally appoint an arbitrator and pay the award given by his arbitration, expenses *re* same, &c., out of this money retained? (3) Can they or can they not lawfully refer the farmer to the contractor and decline to arbitrate or otherwise deal with him regarding the claim in question? Can you quote any case law on all or any of these points?"

Answer.—(1) Subject to the conditions in the contract, the Council may retain the money. (2) Yes. (3) No. The Local Authority are responsible, and they should not decline to arbitrate.

2164.—DRAINAGE OF HOUSES: EASEMENT.—"Q." writes: "Six houses within one curtilage are provided with earth closets, but have the slop drains discharging into a ditch. The owner of the latter has given the owner of the houses notice to cease using the ditch as the drain outfall. The house owner has written me for advice. Will you kindly advise (1) Whether the duty of providing for the disposal of the sewage is cast upon the Authority or the owner? (2) Whether the owner can cut off the connection of the drains with the ditch? (3) Whether there is any simple method of dealing with slop water?"

Answer.—(1) A Local Authority is not required nor can they be compelled to provide for the disposal of sewage for isolated groups of houses. Where no sewer exists, the Local Authority may require the owners to construct cesspools and to drain thereinto, or into such other place as they may direct, as provided by Sec. 23 of the Public Health Act 1875. (2) Not if the owner has acquired through long usage an easement or right to drain into the ditch. (3) Yes. See Thudichum's "Bacterial Treatment of Sewage," price 1s. 3d., obtainable from this office.

2165.—TENTS, VANS, AND SHEDS: BYE-LAWS IN RESPECT TO.—"Surveyor" writes: "I should be pleased to know if Model Bye-laws have been issued under Sec. 9 of the Housing of the

Working Classes Act, 1885, with respect to 'tents, vans, and sheds used for human habitation,' and how such are obtainable."

Answer.—Model Bye-laws with respect to tents, vans, sheds, and similar structures used for human habitation, have been issued by the Local Government Board, and copies of such may be obtained on application to the Board. Annotated copies of such bye-laws may be found in Mackenzie and Handford's "Model Bye-laws," price 25s., obtainable post free at the price named from the office of this journal.

2166.—Water Supply: Power of Local Authority.—"J. W." writes:—"I have obtained a sample of water from a dip well which is used for domestic consumption by the occupiers of three cottages situate in an outlying portion of this district—500 yards from the nearest main supply of water. The analyst's report states that the water is contaminated with organic impurities of a dangerous character, and is unfit for drinking. What powers have this Council to obtain a suitable supply? Can they proceed under Section 70 of the Act of 1875, or does this only apply to rural districts?"

Answer.—If the existing supply of water cannot be made fit for domestic purposes, the Local Authority may obtain an Order under Section 70 to close the well. The owners of the houses may be required to provide a proper supply of water under the provisions of Section 62 of the Act of 1875. A report from the Surveyor of the Urban Authority will be necessary.

2167.—Sanitary Inspector: What are Restrictions as to Age.—"G. W. H." writes:—"Would you kindly advise me whether there are any restrictions as to the age for Sanitary Inspectorships? I notice that advertisements generally prescribe the age to be between 25 and 45 years of age."

Answer.—Excepting that persons under 21 years of age cannot be appointed to the post of Sanitary Inspector, the only restriction is that imposed by Local Authorities that candidates must not exceed 45 years of age. It will rarely be found, we think, that the age is specified to be above 45 years.

2168.—Leaflets for Distribution as to Small-pox.—"J. M." writes:—"Will you kindly inform me where I can procure suitable leaflets for distribution among householders giving precautions to be observed against small-pox?"

Answer.—Leaflets on this and numerous other subjects in connection with sanitary precautions are published by the National Health Society, 53, Berners-street, Oxford-street, London, W., and are supplied at a cheap rate.

2169.—Drainage of House Approved by Local Authority Subsequently Found Defective: Whether Authority Liable.—"R. T." writes:—"At a new house which was recently erected in my district, the drains were tested by me for soundness with the smoke machine. After some defects were remedied I was satisfied as to their soundness. Prior to a certificate for occupation being given I gave my opinion that the drains were satisfactory. Before the house was occupied the lessee had the drains tested by a private sanitary engineer, who found a small defect or two in the drains by using the smoke test. The water test was then applied, when it was found that the drain could not stand such a test. The lessee has now had all the drains taken up from end to end, the pipes being broken in so doing. The drain, I may add, was not tested by me after the ground was filled in. Will you please advise (1) Whether the house having been passed as fit for occupation, can the lessee successfully sue the Local Authority for the cost of the new drain? (2) Can the incoming tenant *legally* have the water test applied without the consent of the owner or the Local Authority, and then try to make them pay for the cost of a new drain?"

Answer.—(1) The Local Authority are in nowise liable in respect to any expenses incurred in relaying drains consequent on their officers having issued a certificate that the house was fit for occupation. The tenant could not succeed in an action against the Authority or its officers. The latter were not employed by the tenant, but by the Authority, and a certificate given under the building bye-laws is not a warranty. The idea that a Local Authority can be successfully sued under such circumstances is absurd. (2) Yes. The tenant has an absolute right to test the drains without seeking the consent either of the owner or the Local Authority.

2170.—Sanitation: Slides for Illustrating Lectures on.—"Nemo" writes:—"Some time ago I noticed in your valuable paper an account of a lecture on 'Sanitation' illustrated by lantern slides. As I have been asked to give a descriptive lecture on the same subject, could you kindly refer me to some good lectures, also some good jokes connected with the subject, informing me where I may obtain lantern slides, and what are the objects of same?"

Answer.—Lantern slides, diagrams, and models for lectures and teachers on hygiene are obtainable from the Sanitary Institute, Parkes Museum, Regent-street, London, W., and also from the Hygienic Referendum, 12, Ferrestone-road, Hornsey, London, N., from whom catalogues of slides, &c., may be obtained. We do not know of any lectures printed and published for sale suitable to the requirements of a lecture. Mr. John Lamb, Sanitary Inspector, Morecambe, recently gave a public lecture on Sanitation, which was appreciatively noticed by the local Press and referred to in our columns. Perhaps Mr. Lamb might on application send the querist a copy of the local newspaper containing the report of his lecture if the querist encloses 2d. in stamps.

STANLEY
Government Contractors.
Makers of Mathematical, Drawing and Surveying Instruments of every Description.
Gold Medals at the Great Exhibitions. Catalogues post free.

NUISANCES AND METHODS OF INSPECTION.[1]

By J. Spottiswoode Cameron, M.B., B.Sc., M.O.H. Leeds.

NUISANCES AND INSANITARY CONDITIONS.

"Nusance, *nocumentum*, or annoyance," said Blackstone[2] upward of a hundred years ago, "signifies anything which worketh hurt, inconvenience, or damage. And nusances are of two kinds; *public* or *common* nusances, which affect the public, and are an annoyance to *all* the king's subjects; for which reason we must refer them to the class of public wrongs, or crimes and misdemesnors: and private nusances," which the writer defines as "anything done to the hurt or annoyance of the lands tenements or hereditaments of another."

"If a man builds a house," says the same writer, "so close to mine that his roof overhangs my roof, and throws the water off his roof on to mine, this is a nusance, for which an action will lie. Likewise to erect a house or other building so near to mine, that it obstructs my antient lights and windows is a nusance of a similar nature. But in this latter case it is necessary that the windows be *antient*; that is, have subsisted there a long time without interruption; otherwise there is no injury done. For he hath as much right to build a new edifice upon his ground, as I have upon mine: since every man may erect what he pleases upon the upright or perpendicular of his own soil, so as not to prejudice what has long been enjoyed by another; and it was my folly to build so near another's ground. Also, if a person keeps his hogs, or other noisome animals, so near the house of another, that the stench of them incommodes him and makes the air unwholesome, this is an injurious nusance, as it tends to deprive him of the use and benefit of his house. A like injury is, if one's neighbour sets up and exercises any offensive trade; as a tanner's, a tallow-chandler's, or the like; for though these are lawful and necessary trades, yet they should be exercised in remote places; for the rule is '*sic utere tuo, ut alienum non laedas*:'[3] this is therefore an actionable nusance. So that the nusances which affect a man's dwelling may be reduced to these three: (1) Overhanging it: which is also a species of trespass, for '*cujus est solum ejus est usque ad coelum*:'[4] (2) Stopping antient lights: and (3) Corrupting the air with noisome smells: for light and air are two indispensable requisites to every dwelling. But depriving one of a mere matter of pleasure, as of a fine prospect, by building a wall, or the like; this, as it abridges nothing really convenient or necessary, is no injury to the sufferer, and is therefore not an actionable nusance."

Again the same author: "If one erects a smelting house for lead so near the land of another, that the vapour and smoke kills his corn and grass, and damages his cattle therein, this is held to be a nusance. And by consequence it follows, that if one does any other act, in itself lawful, which yet being done in that place necessarily tends to the damage of another's property, it is a nusance: for it is incumbent on him to find some other place to do that act, where it will be less offensive. So also, if my neighbour ought to scour a ditch, and does not, whereby my land is overflowed, this is an actionable nusance."

Again according to Sir William: "It is a nusance to stop or divert water that uses to run to another's meadow or mill; to corrupt or poison a water-course, by erecting a dye-house or a lime-pit for the use of trade, in the upper part of the stream; or in short to do any act therein, that in its consequences must necessarily tend to the prejudice of one's neighbour. So closely does the law of England enforce that excellent rule of gospel-morality, of 'doing to others, as we would they should unto ourselves.'"

The foregoing belong chiefly to the class of private wrongs, and as Blackstone points out, "the law gives no private remedy for anything but a private wrong" ("Com.," III. 13, II.). But nuisances are evidently of two kinds, public and private, the remedy for the latter being by action against the wrong-doer on the part of the person injured; the remedy for the former being until lately by "indictment only," except in cases such as where, a ditch having been dug across a public way, and a common nuisance having been thereby caused, the man whose horse is lamed by falling into it has a right of private action against the offender.

Common nuisances, as defined by Blackstone[5], "are a species of offences against the public order and œconomical regimen of the state; being either the doing of a thing to the annoyance of all the King's subjects, or the neglecting to do a thing which the common good requires. . . . Common nusances are such inconvenient or troublesome offences, as annoy the whole community in general, and not merely some particular person; and therefore are indictable only, and not actionable; as it would be unreasonable to multiply suits, by giving every man a separate right of action for what damnifies him in common only with the rest of his fellow-subjects. Of this nature are: (1) Annoyances in *highways*, *bridges*, and public *rivers* by rendering the same inconvenient or dangerous to pass: either positively, by actual obstructions; or negatively, by want of reparations. . . . (2) All those kinds of nusances (such as offensive trades and manufactures), which when injurious to the private man are actionable, are, when detrimental to the public, punishable by public prosecution, and subject to fine according to the quantity of the misdemesnor; and particularly the keeping of hogs in any city or market town is indictable as a public nusance. (3) All disorderly *inns* or *alehouses*. . . . (4) By statute 10 and 11 W. III. c. 17, all *lotteries* are declared to be public nusances. . . . (5) The making and selling of *fire-works* and *squibs*, or throwing them about in any street, is on account of the danger that may ensue to any thatched or timber buildings, declared to be a common nusance, by statute 9 and 10 W. III. c. 7, and therefore punishable by fine. . . . (6) Eaves-droppers, or such as listen under walls or windows or the eaves of a house, to hearken after discourse, and thereupon to form slander and mischievous tales, are a common nusance and presentable at the court-leet or are indictable at the sessions and punishable by fines and finding securities for their good behaviour. (7) Lastly, a *common scold*, *communis rixatrix* (for our law-latin confines it to the feminine gender), is a common nusance to her neighbourhood. For which offence she may be indicted; and, if convicted, shall be sentenced to be placed in a certain engine of correction called the trebucket, castigatory, or *cucking* stool, which in the Saxon language is said to signify the scolding stool; though now it is frequently corrupted into *ducking* stool, because the residue of the judgement is, that, when she is so placed therein, she shall be plunged in the water for her punishment."

I need scarcely remind you that the preferring of an indictment of this last kind does not come within the province of the Nuisance Inspector appointed under the Public Health Act, 1875. The law of nuisance, however, is practically the same as in the time of Blackstone; but to enable it to be more readily brought into

[1] A lecture delivered in the Philosophical Hall, Leeds, April 18th, 1901.

[4] "Whose the soil is, his it is even to the sky.

[5] "Com.," I. 13, II. 8.)

action, recent legislation—nearly all of it dating from the middle of the present century—has established a mode of procedure by which certain common nuisances can be dealt with in a summary manner by the inferior courts. Since 1848 a series of statutes have placed it within the power of Local Authorities to take proceedings against offenders causing annoyance or injury by certain classes of nuisances, and it is the duty of the Sanitary Inspector to ascertain the existence of nuisances of this class, and to bring that existence under the notice of the Sanitary Authority.

We have seen that the legal definition of a nuisance defined by Blackstone is a very much larger one than the practical nuisance with which the Sanitary Inspector has to deal. The question of ancient lights, unless their obstruction renders the house unwholesome, would not come within his cognisance. The freeing of highways from obstructions, the suppression of disorderly alehouses, or the regulation of the sale of fireworks, the prevention of eavesdropping, and the punishment of common scolds, do not come within the province of either the rural or urban Nuisance Inspector. He is really a health officer; he is one of the skirmishers of the great "preventive medicine army" engaged in pushing forward the attack upon disease into the enemy's country, in cutting off the supplies, and demolishing the outworks of pestilence and plague.

The special nuisances with which he has to deal are those which are dangerous or injurious to the health of the community. In the 91st section of the Public Health Act, 1875, seven groups of nuisances are described, which for the purposes of that Act shall be deemed to be nuisances, and liable to be dealt with summarily in the manner therein provided. In six out of the seven of these groups the words "injurious to health" occur. In the first four the words "a nuisance or injurious to health" are found. In the fifth the words "dangerous or injurious" occur, and in the sixth one part of the clause has the words "nuisance or injurious to health," and another part "dangerous or injurious to health," while the seventh sub-section leaves the health question entirely out of the definition. It is evident, therefore, that every nuisance does not need to be proved to be injurious nor even dangerous to health.

This 91st section is so important that I would impress upon all the necessity of committing its words to memory, and I venture to suggest a convenient method of remembering the order in which its sub-sections occur.

The first three of these I keep in mind by remembering the letter "p," and I repeat to myself the words "premises, pools, pigs," not as Mrs. General, the governess in "Little Dorritt," repeated the magic words, "Papa, potatoes, poultry, prunes, and prism," for the sake of making the mouth look pretty, but merely as an aid to memory. "Premises, pools, pigs," remind me that the first sub-section deals with "any premises in such a state as to be a nuisance or injurious to health," in which short phrase might be supposed to be contained, from a sanitary view point, almost all "the law and the prophets." The second sub-section, which I memorise under the word "pools," describes as a nuisance which may be dealt with summarily "any pool, ditch, gutter, watercourse, privy, urinal, cesspool, drain, or ashpit, so foul or in such a state as to be a nuisance or injurious to health." The third sub-section, which, for the sake of alliteration, I remember by the word "pigs," runs as follows:—"Any animal so kept as to be a nuisance or injurious to health."

The fourth and fifth sub-sections I associate with the letter "c," taking the liberty of striking off the first syllable of "ac-cumulation" and the first two syllables of "over-crowded" for that purpose. The sub-sections are thus remembered as "'cumulation," "'crowding." They run as follows:—The fourth, "any accumulation or deposit which is a nuisance or injurious to health;" and the fifth, "any house or part of a house so overcrowded as to be dangerous or injurious to the health of the inmates, whether or not members of the same family."

As already said, the three "p's" and the first "c" require to be nuisances or injurious to health; the second "c," "the house or part of a house overcrowded," need only be so far overcrowded as to be "dangerous or injurious," the proof of actual injury not being therefore necessary.

The sixth and seventh sub-sections I associate with the letter "f," "factories" and "furnaces." The sixth sub-section runs as follows:—"Any factory, workshop, or workplace (not already under the operation of any general Act for the regulation of factories or bakehouses) not kept in a cleanly state, or not ventilated in such a manner as to render harmless, as far as practicable, any gases, vapours, dust, or other impurities generated in the course of the work carried on therein that are a nuisance or injurious to health, or so overcrowded while work is carried on as to be dangerous or injurious to the health of those employed therein." Here, again, the vapours and dust may be a "nuisance or injurious to health, and the overcrowding dangerous or injurious to health." In the seventh sub-section (the furnaces), injuriousness to health is not a necessary part of the offence. The sub-section runs: "Any fireplace or furnace which does not, as far as practicable, consume the smoke arising from the combustible used therein, and which is used for working engines by steam, or in any mill, factory, dyehouse, brewery, bakehouse, or gaswork, or in any manufacturing or trade process whatsoever; and

"Any chimney (not being the chimney of a private dwelling-house) sending forth black smoke in such quantity as to be a nuisance, shall be deemed to be nuisances liable to be dealt with summarily in manner provided by this Act."

To these general clauses there are two provisoes. In the first place, an accumulation or deposit not kept longer than is necessary for the purposes of business or manufacture, and as to which the best available means have been taken for preventing injury to the public health, may escape without a penalty if these facts are proved to the satisfaction of the Court; and, secondarily, in respect to a fireplace or furnace not consuming its own smoke, the Court shall hold that no nuisance is created within the meaning of the Act if it be satisfied that "such fireplace or furnace is constructed in such manner as to consume, as far as practicable, having regard to the nature of the manufacture or trade, all smoke arising therefrom, and that such fireplace or furnace has been carefully attended to by the person having the charge thereof."[6] But even this apparent exception of the seventh sub-section is not really an exception to the general principle that the Act deals with the public health, for it is tacitly understood that smoke is a nuisance injurious to the health of the community, a matter about which I suppose there can be not the "faintest shadow of a doubt."

The corresponding section of the Public Health (London) Act, 1891, has some slight variations from the wording of section 91, 1875. It is the second section of the Act. In the "premises" sub-section, the words "or dangerous" are inserted after "injurious."

In the "pools" sub-section, after the word "watercourse," the words "cistern, water-closet, earth-closet," are inserted, and after the word "drain" the word "dung-pit" is added. The words "or dangerous" are also inserted after "injurious," as in the earlier sub-section.

In the "pigs" sub-section, the word "dangerous' is

6 Further exemptions are made as to smoke in Section 334.

also inserted, and instead of "so kept," the words are "kept in such place or manner."

In the "'cumulation" sub-section the word "dangerous" again appears along with "injurious," and in the "'crowding" sub-section the two words "dangerous or injurious" are altered in their order so as to read "injurious or dangerous," as in the earlier sections.

A separate clause in the London Act contains an enactment about water fittings.

The "factory" sub-section is remodelled altogether, though the meaning is not much changed, and two sub-sections (23 and 24) are given to the subject of smoke prevention.

(To be continued.)

THE SANITARY INSTITUTE.

SEWAGE PURIFICATION AND STANDARDS OF PURITY.

A SESSIONAL meeting of the members of the Sanitary Institute was held on Wednesday, the 17th inst., at the Parkes Museum, Margaret-street, W. Dr. A. Wynter Blyth, M.R.C.S., the Medical Officer of Health for Marylebone, presided, and there was a large attendance.

A discussion on "Sewage Purification and Standards of Purity" was opened by Dr. H. R. KENWOOD, M.B.F.C.S., Assistant Professor of Public Health, University College, and Dr. W. BUTLER, M.B., C.M., the paper being read by the first-named author. They said that the desirability of generally adopting the biological method of sewage purification must depend upon the favourable verdict not of one but of all. The subject was complex, and our knowledge of it still very imperfect. The facts which the work of the past few years appeared to substantiate could be summarised as follows:—(*a*) The biological purification of sewage is not only the most rational but also the most effective method of sewage disposal, and although exaggerated notions as to the economy of the method are very prevalent, it is doubtless cheaper than artificial means of purification; (*b*) that biological purification disposes in a large measure of the sludge difficulty; (*c*) that double contact beds (in which sewage is locked up in the bed) give excellent results with partially sedimented sewage or septic effluent; (*d*) that such contact beds may be worked with satisfactory results when their depth amounts to 12ft.; (*e*) that contact beds 3ft. deep can be worked at the rate of 500,000 gallons per acre in eight-hour cycles (one hour to fill, a rest of two hours, one hour to empty, and four hours rest) per diem as recommended by the Local Government Board; (*f*) that intermittent filtration of sedimented sewage through beds, the outlet pieces of which are constantly open, has given excellent results; (*g*) that the material for the construction of bacterial beds is not of prime importance, so long as the particles are not too fine or too large, and that the best size for the particles probably ranges from about one to two inches; (*h*) that it is very difficult indeed to maintain the capacity of the bed, but the more complete the sedimentation of the sewage the less the holding capacity of the bed is affected; (*i*) different sewages resist the natural agencies of purification very differently, and, therefore, it is not safe to dogmatise that, because one installation gives satisfactory results with a certain sewage, that it will furnish equally satisfactory results with a similar bulk of another sewage; (*j*) that bacterial beds increase in efficiency with use, and some time must elapse before they exert their maximum amount of purification; (*k*) that there is no material difference from the point of view of subsequent purification in the effluents from a closed (septic) tank and a scum tank. It might be disputed whether aërobic or anaërobic conditions are the more favourable for the liquefaction of the organic matter in suspension, and for reducing the stability of the more stable organic matter, but it might be taken for granted that circumstances favouring high oxygenation promote the ultimate changes of purification and the production of an effluent with good physical characters, incapable of putrefaction and developing odour. This condition of things was sought to be conserved in all installations. They attached so much importance to the continuous aëration of the effluent, that in their opinion every effluent drain should be discharged into a shallow open conduit where possible. The distribution of the sewage evenly over a bed is of great importance, even after the sewage has been robbed of the bulk of its suspended matter. The method of applying crude sewage by a single carrier to a coarse continuous contact bed must have the effect of overtaxing the bed on either side of the trough, and such a filter would not be given the best chance of carrying on its work. While it was an open question how far the disintegration, liquefaction, and decomposition of sludge is hastened by maintaining it under strictly anaërobic as against aërobic conditions, it did not appear that there is any gain by keeping the liquid sewage free from contact with the air. Sewage hastens to its ultimate goal of inoffensiveness by the oxidation of its polluting matter, undeterred, and indeed favoured by the fact that from the outfall it is fully exposed to the air. Sewage exhibits a remarkable tendency to aërobic purification, and this is so whether aërobic conditions are favoured or merely permitted. Experiments disclosed instances in which nitrification proceeds at the same rate in the same sewages and effluents under such dissimilar conditions as free exposure in shallow open vessels to the air, and so enclosed in stoppered bottles that there are only a few cubic centimetres of stagnant air above the surface of the liquid. When some of the conditions under which these changes were found to occur were reproduced on a large scale the same results were to be observed. The effluents furnished by similar sewages from a scum tank and a closed septic tank were very similar to each other. The scum provided a cheap roof which preserved the heat in the sewage and promoted bacteriolysis. The advantages of tanks could be summarised as follows: they promote uniformity of effluent, they permit of the digestion of from 30 to 40 per cent. of the solids, while the suspended solids in the effluent were found to amount to only from ten to thirty parts per 100,000, the stability of most of the organic solids is rapidly reduced by a short sojourn in a tank, and subsequent purification facilitated. The sedimentation and liquefaction tank, either open or closed, would almost certainly figure largely in the future, owing to the simplicity of adapting such a method to existing plant, and the less expensive open tank would generally be preferred to the closed tank. An important thing to note, as bearing most directly upon the practicability of a more rapid sedimentation in practice, is the circumstance that when it is necessary to remove the deposited sludge this might be done with but little offence, and when it is applied to land it soon becomes resolved, and no nuisance is appreciated in the immediate neighbourhood. Rapid sedimentation, therefore, appeared to be eminently practicable; and this, followed by the application of the effluent to primary and secondary bacterial beds treated by intermittent contact, with outlet pipes constantly open and fed by sprinklers or Stoddart's distributor, appeared to afford the best means at present known of dealing efficiently with sewage in the shortest time and on the smallest area. Generally speaking, land was becoming too valuable to be put to the purposes of sewage purification, hence the modern endeavour to reproduce all the most

favourable conditions of land and to concentrate them in a small area known as a bacterial bed, but where land suitable in nature and quantity could be procured equally good results are obtainable. A thousand gallons per square yard per 24 hours could often be purified by such beds, and 500 easily; very high figures of oxidised nitrogen were obtained, frequently reading from four to six parts per 100,000, and they had found dissolved oxygen amounting to about seven milligrams per litre. A large proportion of the total nitrogen of the sewage was oxidised nitrate, and the free ammonia might be almost nil. Multiple beds were important for the more rapid completion of a purifying process, the initial stages of which might not be disclosed in the ordinary form of an analysis; by the use of secondary beds a much greater degree of purification could be obtained in a shorter time than by means of primary beds alone. Whilst the discharge of most trade effluents into the general volume of sewage is not attended with any drawbacks, no trade discharges should be allowed which prejudicially affect the treatment of the bulk of the sewage; these should be collected and treated separately. Dealing with the question of the standards of purification, the authors said there was great need of system in the collection of samples, the methods employed for analysis, and the construction of standards. The work of a biological installation was not always manifest in the terms of chemical analysis, and those who had experience of the varying characters of sewage, and even of effluents, would attach a qualified importance to a chemical report expressed in terms of a percentage purification of sewage calculated from the albuminoid ammonia or oxygen absorbed figures. The authors showed the rapid changes which might take place in even a finished effluent, and therefore their observations had been extended over long periods and with many varieties of sewage, but the results were puzzling. For instance, nitrates would increase with amazing rapidity in an effluent, and would with equal astonishing quickness decline. What is needed, undoubtedly is an inclusive estimation of the organic matter still in solution in an effluent, and until that was obtained it was impossible to lay down a hard-and-fast chemical standard applicable to all cases. High nitrates had always been considered desirable in an effluent, but their observations showed that nitrates might be high at one time, and at a later period become enormously reduced. No particular figure could be fixed upon as a standard of oxidised nitrogen. The presence of nitrates in an effluent must not be regarded as a sure index of purification, but if they were found to persist in an inoffensive effluent for a few days after collection, the effluent was not likely to become offensive. One of the best tests for a satisfactory effluent was to see if nitrates are present after incubation at 80 deg. Fah. for forty-eight hours, and if they are it would remain inoffensive, no matter whether the original albuminoid ammonia was ·05 or ·5 parts per 100,000. They were not much disposed to attach importance to the question of effluents containing specific organisms, but the point was one upon which some scientific data would be interesting and valuable.

A long discussion followed, Major-General C. P. Carey, R.E., Mr. W. Scott-Moncrieff, Dr. S. Rideal, Dr. Barwise, Mr. E. G. Parry, the Chairman, and others taking part. A hearty vote of thanks was accorded to Drs. Kenwood and Butler for their valuable paper.

Lovers of the picturesque lament the gradual elimination of thatch for rural cottages and the substitution of slate and tile roofing. But there is something else besides picturesqueness to think about, and the serious fires which have occurred in thatched-roofed villages is at least one reason to be urged in favour of slate and tile.

BUILDING TRADES EXHIBITION.

The fourth biennial Exhibition of the series under the control of Mr. H. Greville Montgomery was opened at the Royal Agricultural Hall, London, on April 17th. There was no formal opening as in previous years, on account of the absence of Lord Wolseley abroad.

The extensive display of necessaries for architects, builders, sanitarians, health officers, and others was exceedingly representative, and Mr. Montgomery's arrangements admirable. Bricks and tiles, pipes and sanitary ware, stones and marbles, glass and pavement lights, carpenters' fittings and builders' sundries, engines and electric wiring, felts, plasters, cements, and non-inflammable fabrics were all on exhibition. The special exhibit by the proprietors of the *Surveyor* was held in the gallery; the smoke abatement section in King Edward's Hall; and the fire prevention section in the Minor Hall. Members of the Institute of Builders and Architectural Association visited the Hall on Friday and Saturday; and subsequently the Institute of Sanitary Engineers and Society of Architects appeared upon the scene. The conference on "The Standardising of Bricks" was fairly well attended.

But we must now indicate the features of the Exhibition for the benefit of readers who were unable to be present. Palmers' travelling cradle is a noteworthy adjunct, whether in a hall or in actual work on Southwark Bridge. Happily, these patent wire-supported travelling cradles are now in vogue, and the London County Council and Corporation Authorities, as well as builders, use them for painting, plumbing, pointing, and stonework. The cradle or boat is raised or lowered by means of ordinary tackle, the head blocks of which run along a wire cable, and, by aid of guy blocks and lines, carries it to any part of the structure being operated by the men in the cradle. The travelling cradle (also the scaffold for interior and ceiling work) have only to be seen to be admired for their utility and facility of adjustment.

Messrs. Joseph Place and Sons, of Darwen, hold the patents for the "Adi" and "Zaza" chimney tops; and we could detect them aloft as we approached. But those overhead had been sold. On the stand were displayed the patent yard gully, which is so much in vogue, and a specimen of their horse manger. There were also end milled bricks in many colours, and salt-glazed bricks of varied utility. The firm had forward a few specimens of the sanitary tubes and stoneware pipes for which they are famed, including Ewings excentric pipe for grouting in waterclogged ground. Messrs. Place and Sons were awarded four gold medals and two silver ones for their sanitary tubes during 1898-99; and the weekly output at Darwen is about fifteen miles per week in sizes from 2in. to 42in. diameter. Several of the patent chequer bricks were also shown, and altogether the display was highly creditable.

Stanley Brothers (Nuneaton) were again to the fore. The space occupied covers 10ft. more than at previous shows, and on this occasion their wares were set off to the best advantage. The office is about 10ft. high, 10ft. long, and 8ft. wide, and is built up outside of bricks of all colours, such as white, blue, granite, buff, ivory, green, yellow, and chocolate. The roof was covered with red roofing tiles, with ridge; and in front over the doorway were a number of vases in which were evergreens, and here and there glazed socket pipes and connections, and red and buff chimney pots. The stand in line was built up pyramidal fashion from the sides, and thereon were terra-cotta ventilators, finials, ridge tiles, ornamental red and buff terra-cotta vases, blue Staffordshire ware, glazed coping to receive fencing, glazed sanitary pipes and connections, &c. There was a medallion of Queen Elizabeth in teapot ware of dark-brown glaze, and two of the late Queen Victoria in buff

and red terra-cotta. In the centre was the face of the Queen, and across "Empress of India," with the words Canada, Australia, New Zealand, Burmah, Africa, Egypt, Gibraltar, Malta, Cyprus, inserted, making a pleasing memorial. Over the top was 1837—1901, and the Royal Arms, with the rose, thistle, and shamrock. It was a fine and artistic display.

Messrs. Ham, Baker, and Co., of Westminster, had a capital show in the gallery, and they made the most of it. There were stand-pipes, hydrants, drilling apparatus for tapping a pipe under pressure, a capital hand pump for contractors, and water-service fittings. Of course, their patent instantaneous penstock, a non-flooding valve, was in the forefront, and it is very useful for basements where it is necessary to prevent a back flow of sewage, and also for bacterial beds. We also noticed the "Bee" water meter, a swivelling hose-cradle, and the waste-preventing post for courtyards, which is so worked that only a limited quantity of water passes out. Indeed, specimens of all the well known specialities of the firm were displayed.

The Albion Clay Company were in the hall as usual, but on this occasion the exhibits were in the gallery and not in the main hall. The show in the bay is very fine, and specimens of the pipes and the connections for which this firm have a great reputation in the sanitary world were set out. It is thoroughly representative, including Sykes' conduit for electric cables, stoneware, drain, and sewer pipes, and Sykes' patent street gulley, for which the firm received the medal of the Institute in 1899. As is well known to our readers, this gulley is made in granitic stoneware to resist great pressure, and is easy of access for cleansing through screw-plugged inspection eye. The bay was fully occupied, but not too crowded, with their specialities.

Mr. W. F. Stanley (of Holborn) has a grand display of mathematical and surveying instruments, which attracted considerable attention. Theodolites, surveying chains, levels, drawing instruments, &c., were nicely arranged in show-cases; but the chief attraction was the exhibition of a printing frame for sun photographs.

The Septic Tank Syndicate illustrate their system with photographs of works carried out under their patents—namely, at Exeter, Yeovil, and Barrhead, near Glasgow. The photographs enable sanitarians to follow the application of the system in towns and villages.

Jennings and sanitary engineering are interchangeable terms, and any builders' show without George Jennings (of Lambeth) would be incomplete. The space is well arranged, and the model bathroom *de luxe* in the style of Louis XIII. is artistically set out. It comprises spray bath in enamelled copper with valves for douches, and mahogany enclosure; cabinet lavatory in Bouge de Verone marble and mahogany enclosure; shampooing valves, cupboard pattern mirror; bidet and footbath, inside lavatory; concealed water-closet without base and with mahogany armchair seat, one of which has been sold to the King. Then there are club, fold-up, cabinet, and new model lavatories; spray, porcelain, and cast iron baths; sinks, and many other sanitary devices, for the Lambeth Works are famed far and near. George Jennings was entrusted with the sanitary arrangements of the foreign residences of the late Queen Victoria, and the firm still maintain their high position as sanitary engineers both at home and abroad.

Mr. Edward Allcott has an effective show of his "red gum" wood for street paving purposes, which is now attracting the attention of municipal and sanitary authorities. The floor of the bay is paved with "red gum" in "herring-bone" style, and proves a veritable object-lesson to all and sundry. Wood paving has taken the place of the older methods in large towns, and "red gum" is now used in Brighton and London, and is about to be used in Southall, Ealing, and Hanwell. This paving has to compete with many rivals, but, being non-porous, it is practically a sanitary paving. Mr. Allcott declares it to be durable, non-slippery, noiseless, and easily cleaned.

Specimens of the manufactures of the Ames-Crosta Sanitary Engineering Company, of Nottingham, are shown to great advantage in the bay they occupy in the gallery. The firm are well known for the excellence of material of their manufactures, and it is only possible to indicate their various specialities. We noticed the surface-water gully for which they received two medals from the Institute, and also the self-adjusting pipe joint, which, it is claimed, is sound, gas and water-tight. The company now make improved "ways" for electric cables of stoneware. At first sight these "ways" seem to be ordinary drain pipes, but on inspection of the inside it may be noticed that there are several "ducts" for cable ways. In jointing the "ways," the same operation is followed as in the drain pipe, but the "withs" which form the divisions do not abut against each other at the ends when the "ways" are laid. The improved form of cable-way is to preserve a perfectly dry "duct." If moisture finds its way into the pipe it would fall to the lower "way" and would be carried off to the "drawing-in" box. Indeed, the aim of the company is to maintain a thoroughly dry duct for the cable.

Messrs. J. Defries and Sons, of Houndsditch, have a small but interesting show in the gallery. There we recognised the famous Pasteur-Chamberland filter, and a number of smaller filters for home use. But possibly municipal authorities and engineers were interested in the Equifex disinfection stove, and the Equifex sewage tank, with a disinfectant exhaust; at all events they got to know all about these specialities.

The Adams' Patent Sewage Lift Company, of London and York, appeal to engineers to examine their syphons. While the apparatus is well known to our readers, the photographs enable engineers to follow the operations of the Adams' system from start to finish. Several forms of automatic sewage lifts are exhibited, and the lifts are shown to be operated by clean water or sewage.

(To be continued.)

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

BRANCH MEETING AT PLYMOUTH.

Members of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health met for the first time at Plymouth on Thursday last. The chair was taken by Dr. Herbert Jones, of Herefordshire (President of the branch), and Dr. F. M. Williams, Medical Officer of Health, of Plymouth, introduced a discussion on "Plague Precautions in Ports." He pointed out that the disease was now pandemic, practically to be met with the whole world over, the infected districts being generally the terminal points for vessels from originally infected ports. It was now admitted that rats were the prime factors in the spread of disease. It was held at one time that plague went along the lines of trade communication, where people went, but that was not necessarily so. Generally, it was found the animals carried it, not the people. His chief point was that no regulations were issued by the Authorities giving power to deal with baggage and cargo on infected vessels, and therein lay a weakness of the system. No suggestion seemed to have been made as to dealing with the importation of rats on such vessels. He was of opinion that some united action was required, and that most stringent regulations should be framed and adhered to in dealing with rats on infected vessels. But a weaker point, and one which, he thought, should be suggested to the Local Government Board, concerned passengers' baggage. A man came, say, from Bombay, who had been living there some

time. At the present moment natives were dying there at the rate of a thousand a week of plague. With the gentleman travelling came a native servant, who might be infected, or who might have been about in the bazaars or anywhere, yet the baggage was in no sense dealt with unless the traveller was known to be an infected person, or the ship was known to be infected. The examination of passengers and crew at present was not sufficient; they should really be stripped, and their temperatures taken, &c., but that would mean a delay of three days, perhaps, and the detention of the vessel. The French did that sort of thing at Suez, but our authorities had no such system. The precautions adopted at Plymouth—nearly every port had its own system—were mainly medical inspection. Outside troopships there would be about sixteen mail boats from infected ports calling at Plymouth each month, and the crews numbered from 100 to 300. If a vessel was certified not infected, all sick cases were satisfactorily examined, and the usual declaration was made by the surgeon to the Customs, the ship was passed. Yet there was a possibility then of a case escaping them, as was so in regard to the Simla recently. Local Authorities had full power to deal with infected soldiers coming home in transports, and the War-office had placed Drake's Island at their disposal, as well as agreed to meet the cost of treatment. With reference to the rats in the town, the Dock Authorities had been notified to give any information in reference to any undue mortality, as they had a good many sailing ships from infected districts discharging grain. Up to the present no action had been taken by the Dock authorities in dealing with the vessels as they were tied up to the quay, as to lifting gangways at night, as to their hawsers, or as to preventors: he was trying to get them to do so. In the town they had made arrangements for the immediate removal of cases either by day or night. He was sorry they had no crematorium, and any bodies of cases who died in the town would have to be buried, but they had made every arrangement even to having large graves, which would be capable of taking a ton of quicklime. Local pilots had notices dealing with plague, cholera, and infectious diseases. There was no list, and none had ever, he believed, been published by the Local Government Board as to infected ports, and they had to glean by newspaper reports which ports were infected. The idea of the authorities seemed to be that any such list would interfere with trade. But it was a serious omission. There should be some arrangement whereby they could get accurate information. He was given to understand that Cape Town and other ports had been infected for months and months, only the matter had been kept quiet.

Dr. Heaven, Dr. J. T. Thomas, Dr. Alford, and the Chairman took part in the discussion, after which Dr. F. M. Martin (Stroud) opened a conversation on "Scarlet Fever and Milk," referring especially to an outbreak of scarlet fever in his district, which was due to milk, and which gave rise to the question as to how far infection could be started by a very mild case such as could hardly be detected. The boy to whom the doctor traced the source of outbreak had, when seen, no real symptoms of the disease. The suggestion was not that the skin spread the disease through the agency of the milk—the boy assisting to milk cows—but that by spitting on his hands, or something of that sort, he had caused the milk to be infected. When the boy was taken from the work the outbreak was readily checked.

In the discussion which followed Dr. Martin's views were endorsed, several of the gentlemen quoting cases which had come under their personal observation.

Dr. Williams remarked that it appeared to him the type of scarlatina had greatly changed of late years, the rash being often missed, and this view was generally shared by the medical gentlemen present.

Dr. Noy Scott invited an opinion as to the probability of bovine scarlet fever, and said the veterinaries he had questioned laughed at the whole thing.

The essayist said he was somewhat sceptical, but thought they must take the position stated by the Local Government Board.

A vote of thanks was passed to the Mayor for the use of the parlour, and the meeting closed.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

The monthly sessional meeting was held on Wednesday, 10th April, Mr. E. R. Palmer, Vice-chairman of Council, presiding, when the following paper was read by Mr. Wm. Elgie Bland, F.I.S.E., A.S.I., of Newcastle-on-Tyne, Inspector of Technical Classes to Durham County Council, on

THE NEED OF UNIVERSAL EDUCATION ON SANITARY MATTERS.

Sanitary science has during the last twenty years made rapid strides, and the general improvement in the health of certain classes of the nation is very marked during that period.

I fear, however, that the experts have advanced so rapidly, that they have left the general public too far behind, for the latter are looking upon them as enthusiasts and faddists, and I am afraid will continue to do so, if we do not make every effort possible to carry them with us in sanitary knowledge, and convince them, (as we ourselves are convinced) of the great benefit the nation will derive by adopting up-to-date sanitary principles.

The value of sanitation is really a personal question, and until the people themselves thoroughly understand the importance of it, and bring the weight of their individual effort to bear on the question, very little real advance in this direction can be made.

I do not suggest that every man and woman should become sanitary experts, but that if we, as a nation, desire to live healthy and cheerful lives, the general public should have a better knowledge of Nature's sanitary laws than exists at present, and should put them into daily practice; and the important mission of educating the people to fully appreciate the advantages of sound sanitation does and should devolve largely upon such institutions as the one whose members I have the honour of addressing to-night.

Perhaps everyone does not admit that this world is a beautiful and pleasant place to live in; it is none the less a fact, and but for man's wilfulness and ignorance in acting contrary to Nature's laws, this fact would be apparent to all. Providence has practically given us the entire control of the bodies in which we live, and the laws we should follow to ensure the healthfulness of these bodies are after all simple, and should be generally understood by all. This being so, it is sad and very wrong to see a great amount of preventible disease and sickness that exists throughout the universe. I say preventible, because we have advanced far enough in sanitary science to know that if the public individually fully realised the value of sanitary knowledge, and would practise it, disease and sickness would be reduced to a minimum, if not practically stamped out altogether.

Surely, then, the subject of hygiene and sanitation should become one of the very first importance in the teaching of our schools; indeed, to my mind, quite as important as either reading, writing, or arithmetic. It is not rare, even in our days, to hear some people contend that disease and sickness are the result of natural causes, over which we have no control, thus blaming an all-wise Providence for what is undoubtedly the result of ignorance and carelessness. For my own part, I

cannot bring myself to believe that a Divine Power ever designed pain, sickness, or misery; to a thinking man everything suggests that our Maker intended man to be physically healthy and happy, and our troubles are simply the inevitable results of our wilfully and carelessly ignoring Nature's simple laws of sanitation.

When we hear the knocking of a faulty or badly-oiled engine, when we see leaks from drains, or corrosion of iron pipes or plates, we are warned that something has gone wrong with or about these things, which should be immediately put in order. So with ourselves, when we are visited by pain or sickness, it should be a warning to us that something has gone wrong with our organism or surroundings, which should be put right with as little delay as possible.

Acts of Parliament are undoubtedly necessary, and do assist sanitary progress by enforcing sanitary discipline, but they can do little towards a permanent cure or prevention, unless supported by the earnest co-operation of each individual; indeed, their success depends entirely upon the manner in which they are individually applied. For instance, the laws of our towns enact that every house shall be supplied with pure water, but they cannot compel each inhabitant to use it. They may stipulate that proper baths, wash-houses, and water-closets shall be provided, but they cannot make people use them. They may stipulate that our streets shall be wide, our windows large, and made to open so as to admit light, sunshine, and air; they cannot, however, prevent people from shutting out these life-giving elements by heavy blinds and curtains; and so I might go on. Therefore we are brought face to face with the fact that success depends solely upon the people being so educated in sanitary matters as to realise fully the enormous responsibility that rests upon them individually in such matters, not only with regard to their own health, but as to the well-being of those about them. This responsibility rests equally upon rich and poor; money will obtain most things in these days, but it cannot purchase perfect health, which God intended as a free gift to all.

It would appear, however, like many other free gifts, it is frequently not properly valued until lost. We are too apt to assume, especially those of us who are robust, that health is a fixed condition, and will care for itself, irrespective of its surroundings or of any unnatural strain we may put upon it, and that no effort is needed on our part to retain it.

Experience, however, very soon convinces us that such is not the case. Health is affected in very many ways; by our occupation and abode, the place we work in, the food and drink we take, the climate, water, drainage, personal cleanliness and general habits of life. All these and many others, as the Sanitary Engineer well knows, affect health, and the very thought and knowledge applied to the proper regulation of these influences for our benefit constitute true sanitation; for without experience and knowledge on sanitary matters we cannot properly regulate such influences.

You will generally find a healthy and happy family associated with good knowledge on sanitary matters, and, as a rule, those who are most careful about their own health are usually most thoughtful for that of their neighbours, and always assist (by their example, at least) in establishing healthy principles amongst the community at large. On the other hand, you usually find dirt and disease associated with ignorance and superstition.

We are told in the Bible that Moses included elementary sanitation in his religious teaching, and that the enforcing of sanitary regulations was part of the priests' and commanders' duties in those days. I would respectfully suggest that the religious preachers of our own time might also, with great advantage, take similar duties upon themselves, for godliness and cleanliness should go hand in hand, and the preacher, being so continually in touch with the people, could do much in the way of educating them in sanitary matters. Of course, it would be necessary that he should first qualify himself for such duties.

One wonders what Moses would have thought of a case that came under my notice some years ago, of the waste pipe from a baptismal font, in a church in the North, being directly connected with the top part of a town sewer, without any trap whatever; at which font hundreds of infants must have been christened with sewer gas as well as water, to say nothing of the atmospheric pollution of the church.

Though we may all agree as to the need of universal education on sanitary matters, the method by which it can be accomplished is not such an easy question to decide; indeed, it is most difficult. I frequently meet with the greatest opposition from seemingly intelligent and educated people, and have my suggestions denounced as absurd fads, which their forefathers managed to do without, and that the sole result of carrying them out would be to bring trouble and needless expense upon the already overburdened householder or landlord. It is no doubt the pocket, rather than the intellect, that dictates such expressions; at the same time, the sanitary profession is not entirely clear of faddists, who are responsible for much of the prejudice which exists; they are, however, the exception and not the rule, and are not likely to increase much as long as we have such institutions as this, to freely discuss and criticise in detail all new ideas, and expose them to the light of practical knowledge and common sense. To those sceptics and grumblers who state that sanitary science, as practised to-day, is unnecessarily faddy, I would suggest a careful comparison of the existing state of things with that of fifty years ago.

Take the dwellings of the middle and artisan classes, with their pure water supply, drainage system, and in many cases baths with a hot supply, and compare them with those of that period. Look at the medical statistics, and see how small-pox, typhoid, cholera, and scarlet fever when threatening to become epidemics are almost immediately stamped out, even in thickly populated districts. Indeed, it is not uncommon to find such districts in our large towns, where proper sanitary regulations exist and are carefully carried out by the people, showing a lower death-rate than country villages, where sanitary matters have never had proper consideration.

Then, again, compare the mortality of our workhouses, hospitals, barracks, and similar institutions to-day with that of the past, and see what sanitary science has done for their inhabitants. Look at the constant water supplies of our large towns and cities, and the careful and efficient manner in which subsoil drainage, sewage systems, &c., are generally dealt with. Are these the work of faddists, I would ask? I think not; they are the direct result of a broader and better knowledge of sanitary science, and their introduction has saved thousands of lives that would have been lost or made miserable under previous conditions. It proves that the advance in sanitation has considerably lengthened the average life of man, to say nothing of the healthier, happier, and more morally favourable conditions of his existence. And this in spite of the fact that his nervous system is subject to a much greater strain than was formerly the case. Between 1850 and 1900 the death-rate has been actually reduced from twenty-three to nineteen per thousand, chiefly on account of improvements in sanitary matters. Surely, then, when such results have been obtained in the face of opposition from a large portion of the population through ignorance of the advantages of reforms, it is fair to assume that, with this opposition removed by a

broader education and knowledge of sanitation, we should soon put an end to preventible disease.

(*To be concluded.*)

At a meeting of the Election Committee, held on the 10th instant, the following were elected as Associates:—S. L. Bartholomew, Clapham; C. E. S. Crawcour, Bray, Ireland; J. Moore, Whitley.

CORRESPONDENCE.

(*To the Editor of* The Sanitary Record.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

THE PLUMBERS' COMPANY AND THE REGISTRATION OF PLUMBERS.

Sir,—The letter of Messrs. Hunter and Haynes, solicitors to the promotors of the Plumbers' Bill, has just come under my notice, and I should be obliged if you would kindly give publicity to the remarks I have to make on the subject in your next issue. If the solicitors who are acting for the promotors of this Bill have to rush into print and try to defend the promoters' position, and ridicule Mr. Greenhall's paper, read before the Institute of Heating and Ventilating Engineers a few weeks ago, then so much the worse for the Bill and the cause of the promotors.

Without traversing the whole case, will the solicitors, in the absence of anyone better qualified than they, answer the following questions:—

(1) Is it not proposed by this Bill to make the plumbing trade a "close profession"?

(2) Is it not a fact that a trade or professional monopoly would be effected?

(3) Is the plumbing trade willing to act as the shoemaker, and "keep to his last" should this Bill become law?

(4) Is it not a fact that the plumbing trade have already, without an Act of Parliament, made certain inroads upon other trades, and allocated to themselves the right to do several kinds of work outside of the real plumbing business?

(5) Is it not a fact that the plumbing trade assert that it is their prerogative to instal all hot-water circulations, cold-water services, fire services, eaves, spouts, and down pipes, whether these be in lead or cast iron, or other metals?

(6) Is it not a fact that the plumbers (masters and operatives combined) elected to strike a job at Leicester because engineers were executing a hot-water service circulation?

(7) Is it not a fact that the same thing has happened in various other parts of England?

(8) Is it not a fact that the plumbers have taken under their special care besides plumbing work proper, *i.e.*, work executed in lead, such trades as the following:—Lead glazing, bells (crank and electric), spouting, electric lighting, speaking tubes, cold and hot-water services, painting and decorating, upholstering, awnings for weddings, carpet beating, linoleums and felts, sash lines and furniture repairs, and even undertaking?

(9) Is it not a fact that plumbers do a great deal of heating work, which rightly belongs to the heating engineer, but which the latter must not grumble about?

(10) Is it not a fact that in some towns where technical schools are established, the plumbers have denied the right to any individuals, other than those serving an apprenticeship (*sic*) to the plumbing trade, to attend the classes for the advancement of technical knowledge in this particular trade, although the schools are all supported by public funds?

(11) Is it a fact that should the plumbers secure the much desired Bill they are promoting, they will stop their aggressive attitude to other legitimate tradesmen, who follow a trade to which they have been apprenticed, and carry out their work in a legitimate and honourable way, particularly as regards engineers, who execute hot-water and cold-water services in metal pipes other than lead.

(12) Will the promoters of this Bill guarantee the Government or the public at large that, should the Bill become law (?), the rising generation of plumbers will be made perfect plumbers?

After stating these questions, I would like to ask if it is reasonable to suppose that Parliament would grant a Charter or an Act of Parliament to make a small handful of men proficient in their calling when they already have the facilities at their hands if they would only avail themselves of them. What is wanted is self-reliance, industry, application, and perseverance, not only for apprentices, but for operatives, old and young as well, to acquire that knowledge that best befits them to carry out that "good workmanship" in sanitary matters which should be incumbent upon any man who pretends to call himself a workman, and without invoking the aid of Parliament to do this for them.

More reciprocity of feeling should be considered by the plumbing trade, and they should let the "live and let live" principle predominate, rather than stimulate ideas which would form a hindrance instead of a progressive step in the beginning of the twentieth century. Public men and newspapers are all telling us just now of the great depression and commercial crisis that is impending in this country owing to foreign competition, and yet we have a City Guild who are apparently so ignorant of their own best interests as to push to extremes a policy that is fraught with the greatest danger to not only the plumbing trade of this country, but to allied trades. If the same energy, the same time and amount of money, spent in promoting this useless Bill were spent in educating the plumber and other allied tradesmen, technically, in the art of science and practical work, some good object would be achieved, and the future generations of both plumbers and public would benefit by it; but as it is at present a great waste is going on. The plumber is jubilant (sometimes defiant) over the possibility of this so-called Act; he has come to the conclusion that should this Act of Parliament only became a reality, the whole of his grievances are at an end, and he will have no more fields to conquer—in fact, the writer has been threatened already that when they (the plumbers) receive their Charter they will show what they intend to do.

Acts of Parliament will not make good plumbers any more than they will make great painters, authors, politicians, or engineers; great and good men must be made by their own conduct in life, the application and study they give to their respective businesses, and this, I think you will agree with me, is the only sure and true way to success. Combinations are useful so long as they are for the general good of the greatest number, but when combinations are made to create monopolies for the benefit of the smallest number, then they are fraught with the greatest possible danger, not only to the general public, but also to the monopoly so created, as their creation stultifies their end, and stops further development and progress.

In conclusion I would say that although my mind is "dead set" against the Bill, I shall not oppose the passing of it so long as the plumber only wants the Act of Parliament to cover legitimate plumbing work, and I think much of the present opposition would be removed if the Plumbers' Guild, or their mouthpiece who has thought fit to champion their cause, would give an undertaking, and circulate the same in all the principal trade journals and newspapers in the country, that it is

not the intention of the Plumbers' Registration Act to be aggressive and oppressive, but that the Act is for matters germane to what is recognised as plumbers' work, and that the plumbers will also reserve for the respective trades the same privileges they have enjoyed since they were apprenticed, viz.:—That engineers may erect any kind of water or other liquid installation, whether it be hot or cold, in any metal pipe other than lead. That ironmongers and other whitesmiths be allowed to carry on the work of their forefathers, so long as the men employed are specially trained for the work, but not by Act of Parliament. That electricians be allowed to fix electric bells and lighting as before. That lead lights and glazing be done by such trades as formerly. That painting and decorating be left to that trade. That undertaking, carpet beating, &c., be left to that class of tradesmen who follow these particular callings, and such like.

Lastly, let me state that there are several classes of water supply to our public buildings which have become specialities in the different trades. The exigencies of the present condition of things has brought this about and demanded it. What I ask is to allow these specialists who have made a constant study of this class of business for many, many years to proceed with the work entrusted to their care to instal, and for which they give a guarantee as to the efficiency and sufficiency of such supplies.

Speaking for the trade of which I have the honour to belong, I wish to say we have no desire to enforce prerogatives, nor do we insist upon a "close profession." If the plumber can do this class of work better than us, in course of time he will get the work instead of us, but I strongly object to a trade using means (not legally or morally right) to stop me and many more like me from pursuing a calling which I have followed as apprentice, journeyman, foreman, manager, and employer for a period of thirty-one years, during which time I have been engaged in executing some of the finest installations of the would-be prescribed class in this country.

I trust that you will be good enough to give the same publicity to this letter as you were kind enough to afford to Messrs. Hunter and Haynes, the solicitors to the promoters of the Bill, which, in my opinion, is a return to practices rampant in the dark and middle ages, when all kinds of abuses and excuses were made to increase the wealth of the already rich.

It is with the object of placing the matter fairly and squarely before your readers that I have ventured to trespass so much upon your space.—Yours faithfully,

London, W.C., FAIRPLAY.
April 20th, 1901.

THE RURAL HOUSING PROBLEM.

SIR,—Will you allow me most emphatically to endorse all that has been said by Mr. Geoffry Drage in his letter to you of the 11th inst?

As to the present deplorable condition of rural housing, I have in my possession ample proofs of the accuracy of those statements which persons who wish to hide the truth, or are unwilling to believe it, are so fond of setting aside as exaggerated. Undoubtedly there should be a Public Health Department with control of all matters pertaining to the public health, and it is to be regretted that there are so few medical men in the House of Commons to further the interests of the public in this direction. Control of the water supplies—so lamentably deficient and polluted in rural districts—should be in the hands of the County Councils, and not of the Rural District Councils.

I should also like to see a Public Prosecutor to take action on behalf of the people when they have suffered serious injury owing to insanitary arrangements which are also illegal. Hundreds die every year from diphtheria, enteric, diarrhœa, and other ailments, and many more suffer from permanent ill-health; and yet these victims and their friends have absolutely no redress, although the illnesses and deaths may have been clearly traced to the poisonous condition of the drainage and water supply, or to the dampness, draughtiness, and general dilapidation of the cottages. It is idle to say that the people need not live in such cottages. If they left them, they would oftener than not be homeless. Medical Officers have no independence of action, and many Inspectors of Nuisances are ignorant and unqualified. If they did their duty they would often be seriously overworked.

The building difficulty is only one part of the great question of rural housing. In a village in Cambridgeshire, with which I am well acquainted, there are at least twenty cottages with only one bedroom and one living-room, and others with two bedrooms in which the second room is so small that in cannot hold a bedstead, and the beds have to be made up on the floor. Many of the cottages are in a deplorable condition, and with bad sanitary arrangements. There is one pump with drinking water for the whole village (population 400), and the people have to fetch it from all distances up to 400 yards. The land and cottages are owned by about nineteen small owners, a college, and one large owner.

The chairman of the Parish Council is a farmer and small owner, and he also represents a neighbouring village on the Rural District Council. In conversation with some of the small owners, I have often expressed the wish that better cottages might be built in the village, and I have always received the same reply, "If good cottages were built no one would want ours, and that would be bad for us." Judging from these facts, it will be realised that Rural District Councils—as so often constituted in the country—do not always want to build even if they could afford it.

Persons who want to find an excuse for leaving matters alone, are fond of saying that if village slum property were condemned, it would tell hardly on widows who have no other means of subsistence.

As far as my experience goes, for every widow who lives on the profits of slum property, there are eight or ten others to whom such profits are not necessary. In the village in question, amongst the small owners are two widows, and the rest are prosperous or retired farmers, carpenter, bricklayer, retired servant, small holder, publican, insurance agent, and others. Several of these who had saved money, have, during the last few years, invested it in dilapidated cottage property as a paying investment. The Sanitary Inspector for this village is a publican and small farmer. Until the Public Health Acts are codified, and their administration placed upon a very much more satisfactory footing than at present, the cheapening of building, and the simplifying of the building laws—desirable as these reforms are—would not always result in the building of cottages in those villages which already possess a fairly sufficient number of the slum kind.—Yours, &c.,

C. COCHRANE (Mem. San. Inst.)
The Downs, St. Neots, April 15th.

THE Mayor of Bournemouth has received a communication from the Local Government Board intimating that it approves of the application of the Town Council to enlarge the borough boundaries by including Winton, Pokesdown, and Southbourne within the area. This will give Bournemouth an additional sea frontage of three or four miles, and will also include extensive pine woods belonging to Lord Leven and Melville, Viscount Portman, and the Shelley estate within the borough. It will also double the size of the borough area, and over thirteen thousand to the population, and extinguish two Urban District Councils and one Parish Council.

LAW CASES.

Failure to provide a Ventilating Shaft.

JOHN B. KYFFIN, a Borough Councillor of Hackney, was summoned to the North London Police-court, to remedy a defective soil-pipe at houses owned by him at Lauriston-road.

Mr. T. H. TIDDEMAN appeared for the Hackney Borough Council, and Mr. ELDRIDGE was counsel for the defendant.

The evidence of the Sanitary Inspector (Samuel Punter) and the Medical Officer (Dr. King Warry) was that there was a nuisance dangerous to health by the fact of there being no ventilating shaft to the sewer.

The contention for the defence was that the ordinary flushing apparatus was sufficient if properly used.

Medical corroboration was called on either side, but in the end

Mr. Fordham thought the proper safeguard was the ventilating shaft, and made an order for a supply of this to each of the houses in question, with £4 4s. costs against the defendant.

Mr. Eldridge said his client would consider whether he would appeal against the decision.

Owners' Liability for Drainage Works.

AT the Bromley Petty Sessions the magistrates were occupied for some considerable time in investigating a summons against Henry Ernest Cox, of 81, Martin's-road, Bromley, for £19 9s. 4d. claimed to be due from him to the Bromley Urban District Council in respect to drainage works carried out in connection with his premises. He disclaimed liability, and was represented by Mr. GEORGE WELLER, Mr. F. H. NORMAN appearing, as Clerk to the Urban District Council, in support of the claim.

Mr. Henry Nye, who is a member of the Council, apparently had some interest in the case, for he occupied a seat on the right of Mr. Weller, and instructed him practically throughout.

Mr. NORMAN opened the case, which was an exceedingly simple one, at some length, stating that the sum of £19 9s. 4d. was the amount apportioned on defendant in respect of taking up and relaying drains in Martin's-road. The drain in question took the drainage of 75, 77, 79, and 81, Martin's-road. Mr. Norman cited the law on the combined drainage question, and put in a letter received from Mr. Henry Clark, dated July 18th, from 27, Simpson's-road, stating that a nuisance existed at the property in question.

Mr. WELLER: What has that to do with me?

The CLERK: Why, that starts the whole thing. There must be a complaint in writing.

Mr. NORMAN then traced the progress of events, putting in the various documents—first, the power to inspect and open, given to the Sanitary Inspector under Section 41; the discovery of the cause of nuisance; the notice to repair, and then the correspondence, from which it appeared that in the first instance the defendant was under the impression that, being a combined drain, it was a sewer repairable by the Authority. However, it appeared that eventually the law was made clear to him, that where the combined drain receives the drainage of houses belonging to two or more different owners, it still remains private property; and on August 11th, the defendant and Mr. Nash, an adjoining owner, wrote to the Council, intimating their desire that the Council would do the work and charge them with the cost. However, the formalities had to be gone through, and finally, the owners failing to comply with the notices, the works were carried out under the superintendence of the Surveyor, at a total cost of £66 10s. 6d., and the amount apportioned to the defendant was £19 9s. 4d. That apportionment had never been formally disputed.

Mr. WELLER: I beg your pardon. It was disputed, and is now.

Mr. NORMAN replied that there was only one way to dispute apportionment, and presumed Mr. Weller knew what that way was. On the demand for payment the defendant asked to inspect the accounts, and was, after some correspondence with the Council, allowed to take a copy of the same. Final demand was served, and that had been ignored, and the proceedings were thus instituted.

Mr. NORMAN was then sworn and deposed to the formal part of his statement on oath.

In cross-examination, Mr. NORMAN said that at first the Surveyor refused to allow Mr. Cox to copy the bills, but finally he was allowed to do so.

The CHAIRMAN said that had nothing to do with the claim now before them.

Mr. Stanley Hawkings, the Surveyor to the Council, then deposed as to the carrying out of the works and produced a plan. He deposed also as to apportioning the cost amongst the several owners.

In cross-examination, Mr. Hawkings informed Mr. Weller that he could not understand Mr. Weller's reference to the rough plan which he put in on behalf of the defendant. He made no estimate of the cost of the work before giving an order for it, but he obtained a tender from one person only. He certainly called that a tender.

Mr. NORMAN asked the Bench to rule that this was totally irrelevant. The question of cost was not for the Bench. Their duties were purely ministerial, so long as the notices were in order.

The CHAIRMAN said that was so. This had nothing to do with the matter.

However, Mr. WELLER pressed the point very closely that a price from one person was not a tender, and finally elicited the remark from Mr. McKewan, one of the Bench, that Mr. Weller was wasting their time.

In further cross-examination, Mr. Hawkings said the work was done by Messrs. Crossley, but there was no contract.

Mr. WELLER then opened the case for the defendant, raising various legal points, the first being under Section 174 of the Act of 1874, as to contracts, that it being over £50 a contract should have been obtained.

Mr. NORMAN said that, as a matter of fact, less than £50 was paid to Messrs. Crossley. However, that did not now arise.

Mr. WELLER also submitted that the sum charged was excessive, and they had tendered £13, which they considered more than sufficient. Mr. WELLER then raised another point on the question of notice and proceedings.

Mr. WILLET advised the Bench that the Council were quite in order in their procedure.

Mr. HENRY NYE was sworn, and explained the plan produced for the defendant, which the Bench accepted. He indicated certain short lengths as to which the defendant denied liability.

In reply to the Bench, Mr. Hawkings said that one short part of the present drain was not shown on his plan, because its existence was not known of when the work was commenced. It was found in the course of the operations, and it was by the direction of Mrs. Cox that the drain was laid in its present form at that point. The portion in question formed a part of the general scheme.

Eventually, the Bench, after a careful consideration in private, ruled that the Council must succeed, and there would be an order for the amount claimed.

Mr. WELLER said he should ask for a case.

THE health of Calcutta is particularly bad, the total mortality being about double the average of the last five years.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

Every surveyor and draughtsman has, from time to time, to avail himself of the use of "French curves" or "ship curves" in drawing-office work, and his experience with these unscientific and haphazard aids is not generally conducive to serenity of temper and disposition. Let me advise all those who have perpetuated the use of such curves to lay them aside and adopt the "R.H.S. curves," which have been prepared after more years of study and practical trial than I care to mention, by that able civil and mechanical engineer and former Professor of Civil and Mechanical Engineering at Mason College, Birmingham, and Tokyo University, Japan—Professor R. H. Smith, A.M.I.C.E., A.I.E.E., M.I.M.E., &c. These curves, or drawing-office curve templates, consist of a set of twenty-three templates, giving all curvatures between 0 and 18ft. radius, and all shapes from ¼in. to 6in. variation of radius per inch arc.

Along the edge of each of the curves a scale of inches decimally divided is scribed and figured. When a part of one of these templates has been found suitable for a portion of a drawing, a note of that part of the template can be made for future reference in pencil or ink on the drawing. Each template or curve is named by its "inches variation of radius of curvature per 1in. length of arc." The series covers practically all the shapes occurring in artistic and technical designing, and in the plotting in diagram form of the results of physical, chemical, or physiological experiment and mathematical calculation, and a very short period of use with them will convince any practical draughtsman of their great superiority over the haphazard and fancy designs in the so-called "French" and "ship" curves. The price of the set of curves is 10s. 6d., and I may add that a book of instructions as to their use is issued with them.

Most Local Authorities now-a-days, I think, prohibit builders and owners who require to connect house drains to sewers from actually interfering with the pipes or conduits forming the sewer. The rule is one which ought to be made general in every district, for it is in the highest degree improper that the irresponsible workmen of builders should be allowed to tamper with, or to cut openings in pipe or brick sewers, where proper junctions have not been left, in order to insert saddle junctions. Just as well might gas or water companies allow builders and owners to make their own connections to gas and water mains as Local Authorities allow them to interfere with sewers. The damage caused to sewers where Local Authorities or their officials are so lax in administration as to permit the indiscriminate breaking into sewers by owners is inconceivable, for it is generally found, if a subsequent opening has to be made by the Surveyor at such points, that the sewer pipes have been broken, the end of the drain has been protruded into the sewer, or a quantity of cement has been allowed to pass into the sewer, any one of which will eventually induce blockage in the flow of sewage.

The importance of Local Authorities retaining absolute control over drain connections cannot be overestimated. Even where the Authority provide and fix actual junctions by their own workmen, free of charge, the practice is to be commended, and I know of many Authorities where this is carried out. On the other hand—and this practice is more general—the Local Authority by regulations made under Sec. 21 of the Act of 1875 enforce the payment of a fee, when the necessary application to the Surveyor is made for a connection, of from 5s. to 21s. to cover the cost of a proper junction and of labour in fixing the junction. Such labour, it should be understood, in no case includes excavation. In some cases a fee of £2 2s. is charged, one half of which is returned after a period of about three months if the surface of the road has been reinstated to the satisfaction of the Council's Surveyor. Some guarantee as to the latter should always be held, for it is inequitable that the public highway, which is provided for the use of all, should be permanently damaged for the benefit of an individual. But in any case Local Authorities should prohibit the indiscriminate tampering of their sewers by owners' and builders' workmen, and by regulation provide for actual junctions with sewers being made by their own staff.

Some zealous Surveyors which I have met from time to time are sufficiently enamoured of assuming the responsibility—which is rarely requited—of undertaking, through the Local Authority, the construction of house drains in public roads from the boundary of private premises to the sewer, the cost of which has, of course, to be borne by the owner. Where such a responsibility can be avoided, the general consensus of opinion among experienced men is that it should be so avoided. The added care and risks which have to be run in the possibility of endangering foundations when open trenches have to be cut, in accidents to foot-passengers or vehicles consequent upon the road being partially obstructed—for it is singular how accidents do happen to litigious persons when a Local Authority may be made defendants in an action—and the multiplication and doubtful recovery of accounts which is inevitable, do not warrant any Surveyor in assuming the burden either for himself or his Authority. There is nothing to recommend it except that of retaining absolute control of the roads, and if this were worth insisting upon, the Authority should equally undertake all work in public roads carried out by gas, water, and electric light companies.

Those of my readers who can afford to visit the Building Trades Exhibition which is being held at the Agricultural Hall, Islington, to-day or to-morrow, Saturday, when it closes, should not neglect the opportunity if possible. The show is better than any of its predecessors, and the municipal engineering section is alone worth a visit.

There is a movement on foot, instituted by the Royal Institute of British Architects and the Institution of Civil Engineers, to bring about, with the assistance of brick manufacturers, uniformity of size in building-bricks, and it is suggested that the length of a brick should be double the width, plus the thickness of one vertical joint; that four courses of bricks and four joints should be equal to 1ft., and that joints should be ½in. thick and an extra $\frac{1}{16}$in., making $\frac{5}{16}$in. for the bed joints to cover irregularities on the bricks, thus giving a standard length of 9½in. centre to centre of joints. The proposal to arrange a definite standard is made on account of the difficulty which is now so general in securing good bonding in consequence of the irregular sizes which are made, and is one which should be supported by municipal engineers, and has much to recommend it. It is intended to hold a conference at the Building Trades Exhibition this day (Friday) at 4 p.m., which will be open to municipal engineers.

Senex.

A model village is about to be erected by the Butterley Colliery Company in the Midlands. The houses will be semi-detached, and each will contain a bath-room, and have attached to it 400 yards of garden, while the houses and streets will be lighted by electricity.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

INSANITARY GOVERNMENT OFFICES.

IN a recent article we dwelt at some length on the insanitary state of affairs existing in the Foreign-office. In the course of that article we pointed out the possibility of a similar state of things exising in other Government departments, and we regret to say our premonition has proved only too true. For some time past the insanitary state of the Post-office has been causing concern to the Telegraph Clerks' Association, who have made what is characterised as a half-hearted attempt to investigate the condition of post-offices generally. One hundred and eighty-two offices were approached, but of this small number it was found that sixty-nine were in a bad sanitary condition, defective ventilation, bad odours, bad drainage, and overcrowding being freely admitted. The Central Telegraph Office is described as being in parts very dirty, deficient in ventilation and exits. In most of the large towns a similar condition exists, and it is notorious that the London city offices are in a condition which it is no exaggeration to term as disgraceful. There are cases where dining-rooms are in close proximity to lavatories, and one can quite believe that the smells in the summer months are at times almost unbearable.

Under the present system the Medical Department of the Post-office is nominally responsible for the cleanly condition of their buildings, and yet it is curious to note what occurred in the General Post-office, London. The staff had complained frequently without avail, but the Committee promised to visit the building and allow one of the staff to show the members round. The result was that the report speaks of the building as incommodious and insanitary, and yet the Medical Department has its headquarters in the chief London office. The whole thing bears out the contention in our previous article, that these offices should be brought under the Factory Acts, and be subject to inspection the same as private workshops. It is, indeed, an anomalous state of affairs that the Government should pass laws for the community which it can of itself set at defiance, and that thousands of civil servants should be subject to conditions from which factory hands are happily exempt. If the Government had done its duty in this respect there would have been little to complain of; but, unfortunately, the very opposite has been demonstrated, and, while contracting itself out of the law of the land, the State has itself proved one of the worst offenders.

We commend these facts to those members of Parliament who have not quite yet forgotten that the British taxpayer exists for other purposes than to be made the victim of increased taxation, that the health of the community is no less important than Imperial aggrandisement, and that there are pressing social problems of the hour awaiting attention, which it is their bounden duty as representatives of the people to push forward. The welfare of the servants of the State may not constitute the alpha and omega of sanitary reform, but it is a striking index to the shortcomings of present-day legislation in matters affecting public health.

The New Scotch Provisional Order Procedure.

THERE has been considerable interest in Scotland during the last few weeks in connection with the inauguration of the new system of Provisional Orders in place of the old Private Bill procedure. The feature of the new system is local inquiry, con-

ducted by a Commission, partly parliamentary in its composition and partly otherwise, instead of inquiry at Westminster, and the very obvious advantage of the new procedure is an enormous saving in expense. An excellent example of the new system was furnished last week in Glasgow. The Provisional Order in this case was promoted by the Corporation, and fell into several branches, the most important of which had reference to sewage purification, authority being asked for the deviation of a certain sewer, part of the general system sanctioned by Parliament in 1898, and the erection of a pumping station in connection with it. As the counsel for the promoters explained in his opening statement, the scheme for the purification of Glasgow sewage, and the restoration of the Clyde to its ancient purity, began in 1894, when the Dalmarnock precipitation works were opened. These dealt with about one-fourth of the sewage of the city, and are now in full operation. In 1896 the Corporation got another Act authorising the construction of a set of sewers with an outfall at Dalmuir, some nine miles below the city, with similar purification works there; and when these are completed, probably in the course of a couple of years, the two sets of works will overtake the whole of the city sewage on the north side of the river. A third Act was obtained in 1898 for the construction of an extensive system to deal with the sewage of the city and neighbourhood on the south of the Clyde, the outfall being at Braehead, several miles down the river, where the works are to be situated. Under this last scheme, the main sewer is to be a high-level one —known as No. 1—running the whole way down to Braehead, at such a level that the sewage carried by it can be treated at the works without requiring to be pumped. Of the other sewers, some discharged by gravitation into No. 1; others, conveying the sewage of those parts of the city below the level of No. 1, had to discharge by means of pumping. Now, it happened that the site of one of these pumping stations was, while the Bill was still before Parliament, taken by the Caledonian Railway Company under compulsory powers for an extension of their line, and the result was that the branch sewer—No. 4—to which it should have been the terminus, led nowhere. The branch sewer was authorised, but as the pumping station, which was absolutely necessary for its connection with the main outfall sewer, was no longer available, the sewer was useless. The Provisional Order has now been brought forward to get over this difficulty. It is necessary to have a deviation from the original line of No. 4 authorised, with a pumping station in another locality, in order to effect the connection which is essential. That, in brief, is the situation with which this part of the Provisional Order is intended to deal. The inquiry was opened in Glasgow last week, and it will at once be seen how much it must conduce to the convenience of all parties interested—quite apart from questions of expense —to have an inquiry of this nature conducted locally. As the proposed site for the new pump-station is in a residential neighbourhood, there is considerable opposition on the part of the residents.

A Sewage Farm Arbitration.

An arbitration of considerable interest to Local Authorities has been brought to a close in London, after a protracted hearing before Sir Frederick Bramwell, C.E. The Corporation of Leicester in 1885 leased a sewage farm on a thirty years' lease from Sir Tristram Tempest, the owner of the Beaumont Leys estate, Leicestershire, and they now seek to acquire it under the Lands Clauses Consolidation Act. The land was originally leased at the rate of 45s. an acre, as agricultural land, and 100 acres of freehold land were sold at £130 per acre. The Corporation offer to pay only agricultural value for the land, and compensation for severance; but Sir Tristram Tempest claims that the whole of the Beaumont Estate has acquired the value of building land, and must be paid for as such. The amount of his claim is £407,944. The expert witnesses who gave evidence on his behalf valued the property at from £400,000 to £416,000; those for the Corporation varied in their estimates from £87,500 to £103,000. Such are the enormous discrepancies in valuations according to the standpoint of the witnesses. The award of the arbitrator will be looked for with interest.

The New Factory Bills.

The text of the Government Bill for the amendment of the Factories and Workshops Acts has now been issued. It contains fifty-three clauses. Power is conferred on the Secretary of State to make regulations for the safety of persons employed in any manufacture, machinery, process or description of manual labour used in factories or workshops which is "dangerous or injurious to health, or dangerous to life or limb, either generally, or in the case of women, children, or any other class of persons." Objections may be lodged to the draft regulations, whereupon the Home Secretary is to hold an inquiry, and the regulations must lie before Parliament for six weeks before coming into operation. The penalty proposed against any owner, occupier, or manager for infringement is a maximum fine of £10 for the first offence, and £2 per day for its continuance after conviction; and "any other person" who is bound to observe the regulation is to be held equally liable. The provisions as to sanitation, the prohibition of home work in any place where there is infectious disease, or which is injurious to health, are very stringent, as are also those dealing with the employment of children about moving machinery, the regulation of steam boilers, and the employment of children and young persons. There are special requirements as to laundries, bakehouses, and tin-meat factories, and some exemptions, such as fish and fruit-preserving businesses, and Irish creameries. The text of the Consolidation Bill has also been issued. It consolidates the provisions of the Factories Acts of 1878, 1883, 1891, and 1895, and the Cotton Cloth

Factories Acts of 1889 and 1897, and repeals those Acts as separate statutes, and it also repeals part of the Railway Employment (Prevention of Accidents) Act, 1900.

R. I. P. H. Congress at Eastbourne.

The arrangements for this important gathering are assuming definite shape, and already a fair outline of the proceedings has been issued. The Congress will open on Thursday, July 25th, when the Duke of Devonshire (who has consented to be President) will deliver an inaugural address. The following day, with Monday and Tuesday in the next week, will be given up to sectional meetings, and already several important papers have been promised. The presidents of the sections are thoroughly representative men, among whom may be mentioned Dr. Newsholme (Medical Officer of Health, Brighton), who will preside over the Preventive Medicine and Vital Statistics Section; Professor Frankland (of Edinburgh University), Chemistry and Meteorology; Sir J. D. Pile (ex-Lord Mayor of Dublin), Parliamentary and Municipal Hygiene; Dr. Frazer (Medical Officer of Health, Portsmouth), Bacteriology and Comparative Pathology; and Mr. R. Maynard Gloyne (Borough Engineer, Eastbourne), Municipal Engineering and Architecture. Among the notabilities who are expected is Professor Koch, the celebrated German *savant*, who has done so much to enlighten the world on the nature of tubercular disease. It is said that he will give at least one special address during the Congress. The social entertainments will be on an elaborate scale. On Saturday, July 27th, excursions will take place to Normanhurst, Battle Abbey, Lewes, Brighton, and Arundel. No doubt the first named will be the most popular, for Lord Brassey expects to be at home, and has promised to entertain a large party. There will also be numerous garden parties, the inevitable dinner, an illuminated fête, and a grand ball. Special arrangements have been made for the Sunday. The Congress sermon will be preached in St. Saviour's Church. Prior to the service the President and delegates will assemble at the Town Hall, where they will form into procession and march to the church. Robes and regalia are to be in evidence. Altogether the meeting promises to be a brilliant one, and the proposed arrangements reflect much credit on the honorary secretaries, Mr. H. West Fovargue (Town Clerk) and Dr. W. G. Willoughby (Medical Officer of Health), who, together with the Mayor, are bearing the burden of the preliminary work.

Progress at Leeds.

When Yorkshiremen once make up their minds to do a thing they do not stop at half measures. They believe in having the best that money can obtain, and if improvements can be made in the administration of an organisation or a city they are quite prepared to adopt them. With this object in view several members of the Sanitary Committee of the City Council have recently visited various towns with a view to see what can be done to improve the working of the Health Department of the City. Last week these members presented a report to the full Committee, in which were embodied the following recommendations:—(1) That a qualified medical man holding a diploma in public health should be appointed Assistant Medical Officer of Health and Chief Inspector of Nuisances, at a commencing salary of £300 per annum; (2) that, inasmuch as the accommodation of the Sanitary Department in the Municipal Buildings is altogether inadequate, and no possibility of increase presents itself, a house or other means of accommodation be found in the city for the purpose of sanitary offices; (3) that additional female Sanitary Inspectors be appointed at the present rate of wages (about £86), and that Miss Sharpells be appointed chief lady inspector at a salary of £100; (4) that voluntary notification of phthisis be sought, and that the inspection of cases and disinfection after death or removal be carried out; (5) that, as there is an extended tramway service in Leeds, and that at no other town visited is a carriage provided, the carriage hitherto employed for the use of heads of departments be discontinued. These recommendations were unanimously approved by the Committee, and we doubt not will receive endorsement when they come before the City Council. Latterly there have been considerable additions to the health staff of Leeds, and the present accommodation is altogether inadequate for the number employed. It is satisfactory to know that the women inspectors have proved so successful that already it is deemed wise to increase their number. This continued advent of women into the ranks of local workers is one of the best features of the day. There is so much that they can do better than men without encroaching in any way into the domain of the latter that no fears need be entertained about their ever obtaining any monopoly of the office. In any district where there are a large number of "home workers" the female inspector is an absolute necessity. This condition prevails in Leeds, and we are not surprised at the recommendation to increase the number of inspectors.

Fighting Malaria in Italy.

Our Consuls often give valuable information on matters other than that of the progress of trade in the countries they reside in. On the question of the sanitary progress of foreign nations their opinion is most valuable, as it is not that of persons paying a flying visit to a place and imagining they can sum up the position at a glance. There is a responsibility resting upon a consul, and he has to be careful that what he states can be substantiated, for people will act upon the strength of his opinion. Our readers are well aware of the interest manifested in recent years in the attempt to discover the secret of malaria—the disease which so long has defied the investigations of scientists. In his last report the British Consul at Naples gives some interesting information on the discovery of a connection be-

tween a certain species of mosquito and malaria. Some years ago, he says, a malaria map of Italy was published for military purposes, marking the worst districts in black, and those where the fever raged with less fierceness in grey; and it was shocking to see the amount of productive ground upon which no labourer could live in the summer season. To till the land or to perform the duties of the counting-house involved a tedious journey every night to a neighbouring hill-top, often many miles off, with an almost equally wearisome journey on the following morning. The question of malaria, he observes, is the most important social and economic question in Italy. Mosquitoes can be kept out of houses by means of wire blinds, and the Mediterranean Railway Company has spent a large sum of money in fitting these to their stations in the malarious districts. They have further provided their pointsmen and others who must be exposed at night with mosquito-proof clothing, and they have added a wire gauze porch to the houses, so that on nights when the temperature is tropical the families may sit out of doors with impunity. The result has been marvellous. To be appointed station-master in these districts was tantamount to a sentence of death, and no man could have his family to live with him in the summer with any prospect of their escaping the scourge, which affects one-third of the communes in Italy with more or less severity. But now the railway company have secured absolute immunity to their servants and their families, and even in such poisonous localities as Battipaglia and San Nicola the families in protected houses have been perfectly healthy.

Insanitary Houses at Dunfermline.

On some land owned by the Dunfermline Corporation a Colliery Company has some houses which have recently been the subject of correspondence between the Scottish Local Government Board and the Corporation. There are, it is said, some ninety-two houses on this property in an uninhabitable condition, twenty-three of them being beyond repair; and the Central Board has given notice that "the premises, or part of them, are of such a construction and in such a state as to be a nuisance or injurious or dangerous to health, that a nuisance therefore exists upon or in premises possessed by the Local Authority, or in which the Local Authority have an interest, and that the Local Authority have neglected or failed to perform the duty imposed upon them by the Public Health Act, 1897, and to take all due proceedings for the removal of the nuisance and preservation of health in the premises in question. The Local Authority are called upon to remove or remedy the nuisance, or take proceedings for the removal thereof within fourteen days, and thereafter to report to the Board what steps have been taken to put the premises in a habitable condition, or to close them, so as to remedy the nuisance referred to. Failing a definite answer to the satisfaction of the Board within twenty-four hours of the expiry of the notice, the Board say they will proceed further in terms of the statute." This is the gist of a communication received last week by the Corporation. A copy was ordered to be sent to the Colliery Company, with a request that it should act according to the terms of its lease and put the houses in proper repair. This, however, will not settle the matter, and the Town Clerk has been urged to investigate the legal position of affairs at the earliest possible moment. Local Authorities, if they expect others to carry out the law, must set an example, and, whatever it may cost, the Corporation must see to it that this insanitary property shall cease to exist.

National Health Society.

OFFICIAL TRANSACTIONS.

The lecturing work in the country districts is now drawing to a close for the season, so that we have very little to record this week. A few applications are still being received for single lectures or short courses, but in most cases the work is suspended until after the summer months.

Examinations have recently been held in Sussex and Oxfordshire, but the results have not yet been received from the Examiner.

Mrs. Westaway is again lecturing at Toynbee Hall, the subject of her two lectures being "The Hygiene of School Life," and "Nervous Diseases."

ASSOCIATION OF NATIONAL HEALTH WORKERS.

The Association has arranged for an interesting series of lectures on different subjects during the week commencing Monday, May 6th. The lectures will be given at 53, Berners-street, W., and all members of the National Health Society are invited to attend. It will be seen that the subjects of the lectures have been most carefully chosen, and are widely interesting and comprehensive.

Monday, May 6th, at 8 p.m.—Nursing as a Profession for Educated Women, by Mrs. Latter, late Matron of Chelsea Infirmary.

Tuesday, May 7th, at 3 p.m.—The Methods of Preventing the Spread of Disease in connection with School Life, by Arthur Newsholme, M.D. (Lond.), D.P.H., Medical Officer of Health for Brighton.

Tuesday, May 7th, at 5.30 p.m.—Women as Sanitary Inspectors, by Miss Alice Busk.

Wednesday, May 8th, at 8 p.m.—Disinfectants, by John Gay, M.R.C.S., L.R.C.P., D.P.H.

Thursday, May 9th, at 8 p.m.—Open-air Treatment of Consumption, by J. Edward Squire, M.D. (Lond.), D.P.H. (Camb.), M.R.C.S.

Friday, May 10th, at 8 p.m.—Vaccination, by Edward J. Steegmann, M.B., D.P.H.

Saturday, May 11th, at 3 p.m.—General Meeting of the Association of National Health Workers.

These Lectures will be given at 53, Berners-street, W., by kind permission of the National Health Society. All members of the National Health Society are invited.

The monthly "At Home" of the Association of National Health Workers will be held on Saturday, April 27th.

THE CHLOROS DISTRIBUTOR.

Recent experiments relating to the cleansing and disinfection of large areas, more particularly in regard to the outbreak of bubonic plague in Glasgow, have apparently borne splendid fruit. The difficulties to be met with in carrying out such cleansing have for a long time been apparent to Sanitary Authorities, but up to the period in question the problem remained unsolved. It was then that a bright idea occurred to Dr. W. J. Howarth, Medical Officer of Health for Derby, who was fortunate in communicating its purport to Mr. E. Shrapnell Smith, in whose astute hands it quickly assumed a practical shape. The result was the invention of the Chloros Distributor, an apparatus which marks a distinct epoch in the sanitation of big towns, from the street mains—the distributor first being inserted between two lengths of hose, and connected by means of a short piece of rubber pipe to the concentrated supply of disinfectant, the valve is then opened, allowing the disinfectant to be drawn into and thoroughly mixed with the water as it passes through the distributor for the final flushing. The flushing is continued until the desired quantity of disinfectant is distributed. In the course of the experiments in question it was demonstrated that with a water pressure in the street mains of 60 lb. per square inch, and distributing the mixture through a $\frac{3}{8}$in. nozzle, one gallon per minute of the disinfectant could be drawn into the distributor. Using a 1in. nozzle two gallons per minute were drawn in as a maximum. This amount can, of course, be regulated by the valve in the distributor to as low as a quantity of one quart per minute if desired. The

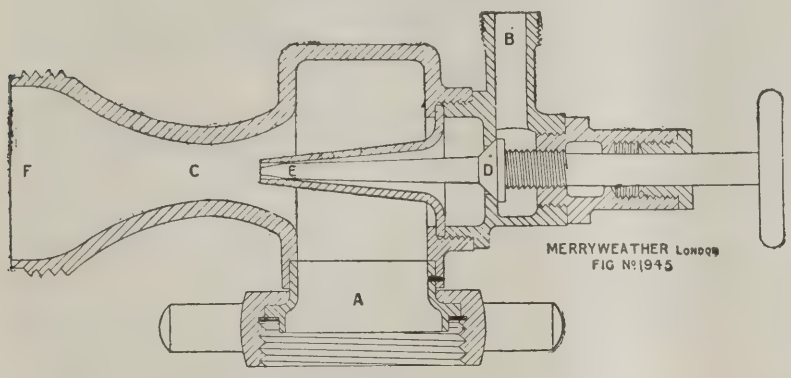
A PRACTICAL DEMONSTRATION OF THE CHLOROS DISTRIBUTOR.

market places, and thickly-populated districts. Like many ideas which accomplish great reforms, the Chloros Distributor is notable for its simplicity. This was effectually demonstrated at a recent trial at Messrs. Merryweather's works at Greenwich, where, before a party of pressmen and others, the distributor was put to a thorough test, performing what was required of it in a most efficient manner. The journey to Greenwich was taken in a motor car, kindly placed at the disposal of the party by the Motor Manufacturing Company, Limited, 47, Holborn-viaduct, E.C., and one cannot forbear confessing that this was not the least enjoyable portion of the demonstration. Arrived at Greenwich, the party adjourned to a spacious yard, where their arrival was evidently anticipated.

The method of working the apparatus (explained on this occasion by Mr. Maryon, Messrs. Merryweather's representative) is simplicity itself. The area is first thoroughly well flushed with plain water through hose manipulation was easily accomplished by two men, and the distributor in action, shown in the annexed illustration, is from an actual photograph taken on the spot. Appended also is a sectional illustration showing the mode of connection, &c. From this it will be seen that the distributor is connected to the hose from the street mains at A, and to the disinfectant supply at B. The water, under pressure from the mains by its increased velocity through the constructed passage C, draws the disinfectant through the pipe B, and the valves D and E, and thoroughly mixes it whilst so doing. The mixture is distributed through a suitable spreader attached to a hose connected to the outlet F. The supply of disinfectant can be regulated to any desired proportion by the adjustment of the needle valve E, or can be shut altogether at the valve D.

Such a practical demonstration of the distributor's efficacy as that afforded on the occasion of the visit to the works of Messrs. Merryweather, who are manufac-

turing the distributors for the patentee, leaves little doubt in our mind as to the important part which it is destined to play in the future, and we shall be very much surprised if it does not speedily become a part of the sanitary equipment of every city and large town in Great Britain and abroad. For abattoirs, fish markets, dairies, courtyards, approaches to fever hospitals, cab ranks, stables, and, in fact, all places where cleansing is



a necessity, it is essentially the one thing needful; and we consider that the United Alkali Company, Limited, through Mr. Shrapnell Smith, has conferred a distinct boon upon the community by placing it on the market. We understand that several large towns have availed themselves of the distributor. To those that have not yet done so we can only urge a thorough investigation into its merits, of which we cannot speak too highly.

REVIEWS.

Sanitary Engineering: A Practical Treatise on the Collection, Removal, and Final Disposal of Sewage, the Design and Construction of Works of Drainage and Sewerage and the Disposal of House Refuse and Sewage Sludge, with numerous Hydraulic Tables, Formulæ, and Memoranda, including an Extensive Series of Tables of Velocity and Discharge of Pipes and Sewers, specially computed by Ganguillet and Kutter's Formula. By Colonel E. S. C. Moore, R.E., M. San. Inst., &c. Second Edition, revised and enlarged, with 860 illustrations, including 92 large folding plates. Large 8vo. 791 pages. Price 32s. net. London: B. T. Batsford.

The fact that the first edition of this admirable work was exhausted within twelve months of its issue is the strongest testimony possible that it filled a want in the literature of the subject of which it treats, and in a manner which no other book now obtainable could do. The first edition found its way, of our knowledge, into the engineering offices of the Local Government Board and all similar Government offices, both in this country and abroad, and, we believe, into the library of almost every municipal engineer in the United Kingdom, and it was recognised as the standard volume of the subject of sanitary and sewerage engineering.

The new edition of the work serves to emphasise the high opinion we formed of the labours of the author when reviewing the first edition, and the exceptional care and ability which have been exercised by him in the compilation of the valuable matter which is found within its pages. The new edition contains some 170 pages of additional information to that contained in the first edition, and all reports, &c., are brought down to date, whilst numerous additional illustrations and plates have been added.

The aim of the author in compiling the volume was, as he states in the preface to the first edition, to bring together in a concise and practical manner such information as was thought to be needed for the guidance of those engaged in the important work of preparing and carrying out schemes for the efficient sanitation of our cities, towns, and villages, whether as engineers, surveyors, Medical Officers of Health, members of Municipal Authorities, or Sanitary Inspectors; in other words, a book of reference for all who are charged with the momentous duty of safeguarding and preserving the public health.

That he has succeeded in his work in every respect is beyond question, and we may add that it would lead to the promotion of efficient sanitation and the public health if this volume were to be studied by all classes of public health officials.

The first chapter in the book deals with the "conservancy" methods of excretal collection and removal. Then follows a chapter dealing with the principles and methods of the sewerage of towns. The flow of liquids in pipes and open channels is treated fully, as is also hydraulic memoranda and tables. Tables of velocity and discharge of sewers, pipes, and conduits occupy, sixty pages. The chapter on "Construction and Materials used in Sewerage and Drainage" is exceptionally well done and includes a description of the apparatus used for the construction and cleansing of drains. The perennial question of the ventilation of house drains and sewers and the numerous methods and devices adopted to combat the evil is dealt with. Chapters on the various kinds of traps used in house drainage, water-closets, and the methods of connection to the soil-pipes, flushing cisterns, sinks, &c., are given and illustrated very freely. Chapters also treat of surface-water collection, subsoil drainage, and "Sanitary Notes," which latter include the methods and apparatus for the testing of house drains and the disinfection of houses.

The subject of sewage disposal of necessity absorbs a considerable amount of space. It would be difficult to discover what system has not been included and described by the author, so well has he done his work. We certainly know of no other volume which contains such a reliable compilation of all the known systems of sewage disposal extant. The details given are ample, and are freely illustrated. There is a good chapter on refuse destructors, as well as one on chimney shafts, and an appendix containing a description of the Southampton sewerage scheme, and Drs. Clowes and Houston's third report on the Bacterial Treatment of London Sewage.

We recommend the second edition of this work to all Municipal Engineers and sanitary officials with the confidence that it is indispensable to them for the proper and efficient discharge of their duties. It is in every respect a capital book, and does infinite credit to author and publisher alike.

At a meeting of the Liverpool City Council last week, it was resolved to appoint a Special Committee to inquire into the condition and circumstances of life, both social and sanitary, of the very poorest of the people of Liverpool and their children. The scope of the inquiry is to be into the character and work in which these people are employed, parents and children alike, the means of getting to their work, the places where they are employed, the character of their dwellings, facilities for instruction, recreation, &c.; nature of prevalent diseases, habits of life, and any other noteworthy or exceptional circumstances in their surroundings.

SANITARY ASSOCIATION OF SCOTLAND.

An examination in Sanitary Science, conducted by this Association, was held at Glasgow on the 9th and 10th inst. Thirty-nine candidates presented themselves, of whom twenty-two passed. The names of the successful candidates are as follows, viz.:—James Anderson, Hamilton; Thomas Bartie, Selkirk; Matilda Campbell, Hamilton; James Carlton, Rothesay; David D. Crichton, Edinburgh; Andrew Crockett, Wishaw; Archibald Eaglesim, Paisley; James B. Easton, Moffat; John Fyfe, jun., Paisley; John R. Haddow, Moffat; Charles S. Jenkins, Glasgow; Allan W. Kennedy, Glasgow; Andrew Mather, jun., Motherwell; James Meiklejohn, Cambusmethan; Archibald A. M'Farlane, Glasgow; Robert M'Nicoll, Perth; Thomas Napier, Rothesay; James H. Patterson, Maryhill; William A. Philp, Glasgow; John C. Smith, Kirn; James A. Waddell, Burntisland; Alexander Young, Cumbernauld, The examiners were John C. M'Vail, M.D., D.P.H. (Camb.), Glasgow; Mr. Gilbert Thomaon, M.A., C.E., Glasgow; Mr. George MacKay, Perth; and Mr. William MacKison, F.R.I.B.A., C.E., Dundee.

Public Works.

SEWERAGE.

The Sevenoaks Council has received sanction to a loan of £3000 for carrying out the Bradbourne storm-water drains.

The Rural District Council of Stokesley has called in Messrs. Fairbank and Son, C.E., of York and Westminster, to prepare a scheme of sewerage and sewage disposal for Kirkleavington, in its Union.

A parliamentary inquiry into the proposed Provincial Order authorising Glasgow Corporation to construct a deviation of an authorised sewer, and conferring certain powers as to lighting and police matters, was opened on Friday last in the Burgh Court Hall.

The Corporation of Glasgow has been granted leave to erect a new and extensive sewage pumping station on vacant ground beside Partick Bridge and across the Kelvin from the machinery section of the Exhibition. The station is a part of the Corporation sewage scheme.

During a discussion on the report on the new sewage disposal works at the Bakewell Urban District Council, the Chairman stated that the engineers recommended the spending of £5000, and that meant a 12in. drain from the centre of the town, and running past the cattle market, along Granby-road, down Haddon-road, to the Willow Bed, and there septic tanks would be placed to receive the sewage of the town.

Having regard to the construction, at an early date, of tramways in Waterloo-road, Darlington-street, Lichfield-street, Piper's-row, Bilston-street, and Bilston-road, the Wolverhampton Sewerage Committee has instructed the Borough Surveyor to thoroughly consider the question of the storm and foul sewers in these thoroughfares and report whether any, and if so, what works were required in order to put the same in a good and satisfactory condition. A lengthy report has now been presented by the Borough Engineer, in which he recommends the construction of foul sewers, man-holes, and lamp-holes, between Molineux-alley and New Hampton-road; opposite the Baptist Chapel, Waterloo-road; Chapel-ash, Piper's-row, Bilston-street, Bilston-road; also a storm sewer between New Hampton-road and Bath-road, enlargement and extension of the storm sewer in Bath-road and other parts of the town, at a total cost of £876.

Mr. A. H. Smith, the arbitrator appointed by the Board of Trade on the Brynmenyn sewerage scheme, sat at the Dunraven Arms, Bridgend, on Wednesday in last week. There was a considerable difference in the valuations given on either side. The Arbitrator reserved his award.

The Nuneaton sewerage works at Hartshill are fast being got into shape. Some idea can now be formed of the extent of the scheme. Several of the beds have been laid out, and the works will cover a large piece of land when completed. The aspect of the district has already been very much altered by the operations.

At a recent meeting of the Bromsgrove Rural District Council, a report was received from Mr. Fiddian, engineer, Stourbridge, on the scheme for the drainage of Alvechurch. He suggested several modifications, and expressed the opinion that the estimate of the cost (£1200) was rather too low. It was decided to let the matter remain in abeyance until a report had been received from the County Medical Officer.

At a recent meeting of the Aberdeen Town Council, the Finance Committee reported that it had before it a statement prepared by the City Chamberlain in connection with the sewerage reconstruction account, and recommended the Council to give the statutory notice of its intention to borrow £20,000 on the security of the sewer rate, for the purpose of defraying the cost of making, reconstructing, and purchasing sewers. The minute was agreed to.

The Town Clerk of Sheffield has written the Norton Rural District Council stating that inasmuch as the objections of the Local Government Board with regard to the drainage of Dore emptying into the Sheffield sewers had now been removed, he saw no reason why the District Council's application should not be fully considered, and the terms for the admission of the sewage discussed, and that the Sewage Disposal Sub-committee had received instructions to deal with the matter.

At a special meeting of the Carnarvon Town Council, the estimates for the ensuing year were discussed. It was decided to make a district rate of 2s. 7d. in the £, to meet an estimated expenditure of £5443, of which £1978 is to be met in a way other than from the rates. A communication was received from the Local Government Board intimating that it would not sanction a further loan of £2200 for water supply purposes until the Council had carried on the other part of the scheme, which consisted of sewerage works at Rhyddu, as a protection against the pollution of the supply.

A special meeting of the Swansea County Borough Council was held last week to further consider the question of the Brynmill sewerage scheme. An amendment to the minute of the Water and Sewage Committee adopting the original scheme sanctioned by the Local Government Board was proposed. This amendment adopted the Pier-head scheme. The discussion on this was now continued, and the amendment was carried by fourteen votes to thirteen. Dr. Rawlings urged that the introduction of the septic tank would do away with every objection which had been urged against that scheme. It would save them £30,000, and would serve the needs of the district well, and for many years to come. After considerable discussion, Dr. Rawlings' amendment was put, and carried. The adopted scheme will deal with the sewage of a population estimated at 6500, living in 1037 houses, with an area of 270 acres, in the western and north-western part of Swansea town, and extending eastward as far as Uplands-terrace and Rhyddings Park-road. It will discharge by a sewer starting at the bottom of Brynmill-road, running thence seaward into the bay for a distance of nearly a mile in a south-south-easterly direction, and discharging at low-water mark spring tide.

A Local Government Board inquiry was held at West Bridgford last Thursday with reference to an application by the West Bridgford Urban District Council for sanction to borrow £7421 for the purchase of land adjoining its sewage farm for purposes of a refuse destructor, sewage disposal, stabling, &c., and £1100 for works of sewage disposal. Mr. Redgate, at the outset, stated that the population of the parish was now 7500, and the assessable value, in September, was £31,795 14s. With regard to the application for £1100, in 1899 the Council obtained sanction to borrow £4454 for a sewage disposal scheme of septic tanks and bacteria beds. This work was practically completed, but from the particulars furnished to the Board it would be seen that the estimate was too small, and that in carrying out the work other expenditure was incurred, chiefly through improvements to the patent alternating gear, so that the Council found it was short to the extent of £1100, for which it was now asking sanction to borrow.

The Birmingham Tame and Rea District Drainage Board has adopted a scheme under which a piece of land is to be sold to the Birmingham Corporation for the erection of a destructor, the heat from which will be utilised for the generation of electrical power to be supplied to the farm, on payment by the Board. The Chairman (Alderman Baker) pointed out that this would effect a saving in the cost of distributing the sludge, and would enable the whole of the farm, instead of only the Saltley portion, to be utilised for this purpose. It was decided to apply for sanction to loans to the amount of £22,000 for plant in connection with the scheme. On the adoption of the Works Committee's report being moved, Alderman Clayton pointed out that the engineer's recommendations appended to it involved a complete change in their system, namely, the adoption of the bacterial treatment of sewage. He suggested that if they had had the aid of modern science earlier they would have required a great deal less land. The Chairman and others replied that the new treatment was only in the experimental stage three or four years ago.

WATER.

The Government of Madras has sanctioned an estimate of Rs. 115,000 for the improvement of the water supply of Tuticorin.

At a recent meeting of the Skipton Rural District Council it was stated that the Kildwick water scheme had been satisfactorily completed.

A recommendation of the Wolverhampton Water Committee to purchase a gravity filtration plant for use at Cosford at a cost of £3500 has been adopted by the Council.

Col. Pepper, an Inspector of the Local Government Board, held an inquiry at Hythe recently into the application of the Town Council for sanction to a loan of £2800 for street improvements and £1400 for waterworks.

The St. Just Urban District Council having applied for sanction to borrow £3483 for works of water supply for St. Just Church Town, Mr. W. O. E. Meade King, M. Inst. C.E., recently held an inquiry on behalf of the Local Government Board.

A Local Government Board inquiry has been held at Rochford with reference to the proposal of the Rochford District Council to borrow £25,000 for works of water supply for Hadley, Hawkwell, Hockley, Rayleigh, Rochford, and South Benfleet.

The Linlithgow District Committee of the County Council has resolved to form the parish of Abercorn into a special water supply district. Objections to the proposal have been taken by the North British Railway Company and Messrs. James Ross and Company, Philpstoun Oilworks.

The Morley Town Council is about to construct additional water works at an estimated cost of £18,000; £4600 is also to be spent by that Council on stables and horses.

The Water Committee of the Dundee Town Council has had under consideration a complaint regarding want of water at University College, Dundee. It has been agreed to lay a 6in. main pipe in place of the 2½in. main in Small's Wynd.

At last week's meeting of the Southwark Borough Council Mr. Westcott moved a resolution expressing indignation at the action of the Government in causing the Water Bill of the London County Council to be thrown out by the House of Commons. The resolution was carried with only two dissentients.

With reference to the Rimington water scheme, the Surveyor has submitted a statement to the Bowland Rural District Council showing that the distance from the source of supply to the top of the village of Rimington was two miles, and the cost of laying a 3in. pipe with main tank, &c., would be £746; 2in. and 3in. pipes, the distance divided, £620; with 2in. pipes, £497. The scheme affected nine farms, one public-house, and ten cottage houses.

At the last fortnightly meeting of the Water Committee the engineer reported that the distribution of water both within and outside of the compulsory limits for the fortnight ending April 13th amounted to 350,306,000 gallons, compared with 58,269,000 gallons in the corresponding period of last year. The Chairman remarked that although there had been a decrease in the consumption of water, the revenue, fortunately, so far this year, showed an advance from £35,000 to £37,000. On the motion of Mr. J. T. Wood a vote of thanks was passed to Sir Thomas Hughes for his kindness in attending and giving evidence to the Royal Commission on Salmon Fisheries.

At the annual meeting of the shareholders of the Beverley Waterworks Company, the directors reported that pensions for the year ending March 31st last had been £1694 4s. 9d., against £1665 0s. 2d. for the preceding year. The working expenses had been £27 more than last year, owing chiefly to the very high price of engine coals and to extensions during the year. A new well had been sunk at the pumping station and the old well deepened, both being now 190ft. deep. The profit, after paying working expenses and laying new water services, had been £807 18s. 4d., which, after paying debenture interest and other preferential charges, and writing off irrecoverable arrears, left a surplus of £439 19s. 11d. It was decided, on the recommendation of the directors, to pay a dividend of 4s. 6d. per share (£10) and to carry the balance, £34 19s. 11d., to the extension account 1898 R.

The report by Sir William Crookes and Professor Dewar on the composition and quality of the water supplied to London last month states that they examined 208 samples and found all to be clear, bright, and well filtered. The rainfall at Oxford during the month was 1·44in., or 0·03in. below the average for the last 35 years, and the total deficit for the year is 1·56in., or 29·1 per cent. on the 35 years' average. Of the 467 samples of impounded and filtered water supplied to London, examined bacteriologically during the past month, 20 samples, or 4·2 per cent., were sterile. Only 10 samples out of the total number examined contained more than 150 microbes, and 29 samples, or 6·2 per cent., contained more than 100 microbes per c.c. The mean of the microbes in the excess samples was 162, against a corresponding mean last month of 151. Nearly the whole of the excess results occurred during the early part of the month, when the climatic conditions were unusually exceptional.

THE Easingwold Rural District Council had before it at a recent meeting the tenders for Contract A for the district waterworks, viz., for the supplying and laying of some 29 miles of water mains, valves, hydrants, &c. The tender of Mr. Charles Firth, of Scarborough, for £13,186, was accepted by the engineers. Messrs. Fairbank and Son, civil engineers, of York, were instructed to proceed with the works with as little delay as possible.

LAST week the chairman (Alderman Holdsworth) and deputy-chairman (Alderman Milner) of the Water Committee, and the chairman (Mr. Trotter) and the deputy-chairman (Mr. Triffitt) of the Baths Committee of the Bradford Corporation conferred together, with the aid of the Mayor (Mr. W. C. Lupton), with a view to the settlement of the question which has arisen between these two Committees in regard to the charges for water supplied to the public baths. The conference arose out of Alderman Holdsworth's notice of resolution for the Council meeting of to-day rescinding a motion passed at the last previous meeting of that body directing that the charge should not exceed 3d. per 1000 gallons. It was agreed that Alderman Holdsworth should withdraw his motion for the present, without prejudice to his right of further action, pending a discussion of the question by the two Committees.

THE ceremony of turning the first sod of the Bewdley waterworks was performed last week by the Mayor of that borough, Mr. Langley Kitchin. For a long time past Bewdley has greatly needed a public water supply, and there has been intermittent discussion of the question for twenty or twenty-five years. The Corporation has adopted a scheme put before it by Mr. Berrington, C.E., of Wolverhampton, and gets its supply of water from a well bored through the new red sandstone near Blackstone rock, on the Severn side—a spot well known to visitors to Bewdley. There is a 12in. bore hole, sent down a depth of 200ft., and this will give a supply of 300,000 gallons of water per day—enough for the wants of Bedley and also of Wribbenhall, if the latter place should wish to take a supply of water from this source. The water is to be pumped to a reservoir on Mount Pleasant, a spot which is notable for its clump of firs, which have long been a landmark to oarsmen on the Severn. The reservoir at this point will afford storage for 200,000 gallons of water, and will meet the wants of the lower part of Bewdley. There will be another reservoir at an elevation of 535ft. above sea level on the Cleobury-road, and this will store 60,000 gallons of water, and supply the high-lying part of Bewdley. The contract for the work is £10,600.

LIGHTING.

THE Wells Town Council has decided to offer for sale their Provisional Order for electric lighting.

A PETITION has been lodged in favour of the Yorkshire Electric Power Bill by the Mirfield Urban District Council.

THE Worksop Urban District Council has decided that steps be taken to obtain a loan of £10,000 for electric lighting.

THE Wolverhampton Town Council has received the sanction of the Local Government Board to a loan for electric lighting purposes.

THE sanction of the Local Government Board to the borrowing of £2529 for the extension of the gas mains has been received by the Abertillery District Council.

THE Colwyn Bay District Council has received several tenders in connection with the extension of the electric lighting plans, and the following contracts have been given to Messrs. Bertam, Thomas, and Co., Manchester:—Water-tube boiler, &c., £1298; switchboard, £63; and dynamo, £1347.

ELECTRIC lighting works are to be carried out in the urban district of Hoylake and West Kirby, at a cost of £12,000.

A GOVERNMENT inquiry was opened at Leeds last week into the proposal to borrow £500,000 for electric lighting purposes in Leeds.

THE contract for the electric installation at the Victoria Infirmary, Glasgow, has been placed with R. D. Cassells and Co., Glasgow.

COLONEL W. LANGTON COKE, M.I.C.E., held an inquiry at Cheltenham recently to inquire into an application by the Town Council for sanction to a loan of £6150 for the purpose of electric lighting.

THE new company which has taken over the Wivenhoe Gasworks has decided to reduce the price of gas from 5s. 10d. to 5s. 6d. per 1000 cubic feet for illuminating purposes, and to 4s. 6d. per 1000 feet for cooking and motive power.

THE Arbroath Gas Corporation some time ago decided to undertake the electric lighting of the burgh in preference to handing it over to a company. At a meeting of the Corporation last week it was decided that, while adhering to its former position, in consideration of special circumstances, it resolves to delay the whole matter for further consideration.

A MEETING of the Works Committee of the Hull City Corporation was held recently, when it was resolved to accept the offer of the Electric Lighting Committee to erect twelve electric arc lamps in the new street from Whitefriargate Bridge to Prospect-street. The cost per each lamp will be £22 per annum. Alderman Larard stated that the difference between gas and electricity would be about £40 in favour of the former.

THE Scunthorpe gasworks are now completed. Mr. Stevenson, the gas and waterworks engineer, has made a thorough inspection, and expressed himself well satisfied. Within a fortnight the ratepayers will be supplied with gas from their own works. The position with regard to the waterworks is just now one of anxious suspense for all concerned. The first tests have proved the water to be too salt for drinking, and too hard for domestic purposes. It is probable that the opinion of one of the highest authorities on water supply in England will be taken on the present position before further experiments are made.

THE Committee of the Newburgh Town Council appointed to make inquiries into the potentialities of the water power in the neighbourhood for an electric installation, accompanied by the Town Clerk, Mr. A. M. Sneddon, and Mr. Hawton, electrical engineer, visited Lochmill, Craigmill, and other places of interest last Thursday afternoon. A report will be prepared shortly as to the feasibility of a scheme, and the advantages of water and engine power, as well as general cost. A number of successful installations have been introduced into small English towns, copying the experience of Swiss towns, where they are common.

THE newly-appointed Electric Lighting Committee of the Northfleet Council reports that after carefully considering the status and experience of the various electrical engineers whose names had been introduced to the Committee, the Clerk was instructed to write Messrs. Preece and Cardew to ascertain the terms upon which they would undertake to advise in matters electric. The Clerk was also instructed by the Committee to approach the Committee of the Gravesend Town Council to ascertain whether, in view of the fact that they were advised that a united district for matters electric was unknown to the law except when constituted by special Act of Parliament, they would entertain a scheme whereby Northfleet could take from Gravesend a supply of electricity at a price based on profit and loss for a limited term of years.

GENERAL.

The Ramsgate Corporation has decided to provide a lodge and ladies' lavatory at Ellington Park.

The Chester Town Council has decided to adopt Part III. of the Housing of the Working Classes Act, 1890.

The Bromley and Beckenham Joint Hospital Board is about to enlarge its hospital by the erection of new diphtheria wards.

The Local Government Board has sanctioned the borrowing by the Lymington Town Council of £2500 for the paving of Quay-hill, High-street.

We understand that the Corporation of London, Liverpool, and Manchester have each contributed the sum of 100 guineas to the funds of the British Congress on Tuberculosis.

A Local Government Board inquiry has been held by Mr. Ducat at Gosport into the application of the Gosport District Council to borrow £3840 for the purpose of erecting workmen's dwellings.

The census which has just been taken of Sydney (New South Wales) and suburbs, comprising an area of 142 square miles, shows a population of 488,968, being an increase of 102,109 during the last decade.

We understand that Lord George Hamilton, Secretary of State for India, has accepted the invitation of the Ealing Urban District Council to perform the ceremony of declaring the Walpole Park open on May 1st. The park, which is about thirty acres in extent, has been acquired by the District Council from Sir Spencer Walpole for the sum of £40,000. It was formerly for many years the residence of the late Right Hon. Sir S. H. Walpole, who died there in 1898. The park is well wooded, and it is intended as far as possible to retain it in its present form.

We clip the following from the *South African Review*:—"On the outbreak of the bubonic plague the Town Council began to abuse the public for their dirty habits, and to issue a series of proclamations and edicts concerning what we ought to do, or ought not to do, conveniently leaving out of consideration their own shortcomings. Amongst the documents issued was one warning the inhabitants against placing house-refuse receptacles in the public streets. As far as I can make out, the only person who has infringed this regulation is Mr. Wynne Roberts, our City Engineer, who was brought before the magistrate on Tuesday last, the 19th inst., and fined 5s. as punishment for his crime." We are indeed surprised that any public officer should set so lax an example, and it is greatly to the credit of the Authorities that they did not hesitate to prosecute him.

The Rev. Andrew J. Forson, Morison E.U. Church, Dundee, recently visited the slums of the city, and has given his impression of what he saw there. In some cases, he says, the houses at which he called were mere shells, small rooms, and with little or no furniture. In order to remedy the fearful state in which several of the people in the slums lived there must, in his opinion, be a systematic visitation of these districts. If some of the men in the Church were to visit the houses and advise the people there in regard to their intemperate habits and get them to sign the pledge and keep a close watch over them, great good could be done. This was the particular work to which he invited those men who were willing to do some real and lasting good in the community. There was great scope in the slums for women workers. They could get the women of the slums to sign the pledge, teach them cleanliness, and give practical encouragement to those who showed signs of improvement. It was in work of this nature alone that they could hope for a betterment of the conditions of slum life.

The Beverley Town Council has resolved to procure a steam roller from Messrs. C. Burrell and Son, at a cost of £433 6s.

The movement for securing better cottage accommodation for the labourers in Ireland is alleged to be creating ill-feeling on the part of the farmers in the South of Ireland.

A Local Government Board inquiry has been held at Clayton by Lieut.-Col. A. C. Smith relative to an application of the Council for sanction to borrow certain moneys for improvement works, as follows:—£3779 for works of private street improvements, £683 for public street improvements, paving of Albert and back Albert-street (which is a highway repairable by the ratepayers), and £1700 for purposes of public offices.

In his report to the Merthyr District Council for the year 1900, Dr. Simons, the late Medical Officer, referring to the question of overcrowding and the housing of the working classes, says that overcrowding is common all over the district. The class of houses proposed to be built were not the class which were overcrowded. What was wanted were houses to let at 10s. to 15s. per month. The closing of insanitary houses should be proceeded with.

The sum originally offered by Mr. Carnegie to build and equip at Dunfermline the baths and gymnasium was £20,000. Competitive plans were sent in, and it was found that in every case the probable cost exceeded the sum at the committee's disposal. Mr. Carnegie has since agreed to increase the amount he had offered for the construction and equipment of the proposed buildings, so that the committee might be free to choose the design which they thought most suitable; but he relies on the committee satisfying themselves that the accommodation to be provided, while ample, should not be in excess of the probable future requirements of the town, and that there should be no expenditure on needless display. The town is providing a site for the new buildings at a cost of £4000.

A Board of Trade inquiry has just been held at Cardiff by Major Druitt into an application of the Corporation for sanction to a loan of £277,630 for tramway purposes. It was stated that tramways are to be worked on the overhead trolley system, and, reduced to single lines, they will run to fifteen miles. As to the £850,000 authorised under the Act for new tramways in the borough, it was stated that, after deducting the amounts expended and estimated to be expended for the construction and electrical equipment of the tracks and wood paving of the roads, there remains a balance of £144,614 to be borrowed for new tramways, and this sum is included in the sum of £277,630, the subject of the present inquiry. A further application is to be made in due course for sanction to a loan for the acquisition and conversion of the existing tramways.

Last week at the Wolverhampton Town Council the recommendation that the salary of Dr. Malet, Medical Officer of Health, be increased to £400 per annum was approved, but before it was passed Councillor Pratt said that, in view of the increase in that department of up-to-date towns, it was necessary that the Medical Officer should give the borough his whole time. Fresh work should, in view of the rapidity with which things were moving, be undertaken if Wolverhampton was to keep in the van. They could not have a better man for the post, but he should give the town the greater part of his services, with, of course, an adequate salary. Alderman W. H. Jones, while in sympathy with the general trend of Councillor Pratt's remarks, thought it was too much to expect Dr. Malet to give up the offices he held as a medical man, for his services were much required. Councillor George R. Thorne said it was difficult at that juncture to discuss such a change of policy.

Last Monday the London County Council (General Powers) Bill came before Mr. Campion, one of the Examiners of Standing Order Proofs of the House of Commons, on an application for leave to insert an additional provision. The new provision deals with the acquisition of Horniman Park and Museum, in the parish of Lewisham (formerly in the parish of St. Giles, Camberwell). The buildings and estate—fifteen acres in extent—have lately been presented to the Council by Mr. Frederick John Horniman, of Falmouth House, Hyde Park-terrace, and as certain of the houses are still in the hands of tenants the Council were in doubt as to whether they could proceed to devote the property to the use of the public without legislative powers, hence the new provision. The Examiner found that the notices required by the Standing Orders had not (by the necessities of the case) been given, and reported non-compliance. The Standing Orders Committee will consider whether the rules in the case of the new provision shall be dispensed with.

On the invitation of the Cleansing Committee of the Glasgow Corporation, a large company recently visited the refuse despatch works, Charles-street, St. Rollox, Glasgow, to see started the clinker-crushing and screening machinery which has recently been erected there. All the refuse collected throughout Glasgow during the night is now mechanically treated, and is either cremated or despatched by rail to the country by the following morning. As the result of the cremation there is a residuum of about 30 per cent. of clinker. As it has been subjected to a heat of from 1700 deg. to 2000 deg., it is perfectly innocuous. To meet the requirements of customers, the Committee has now erected screening machinery, which enables the department to produce the clinker in five different sizes, viz.:—Sand through ¼in. ring, and clinker through ¾in., 1¼in., 1¾in., and 2in. rings. By this means the clinker is thoroughly cleaned, and being harder and lighter than broken bricks or other material, it is admirably adapted for making concrete. A straining test of 410 lb. per square inch has been applied with satisfactory results.

A Local Government Board inquiry was held on Friday last at the Stratford Town Hall, with reference to an application for the issue of a Provisional Order or Orders under Sec. 303 of the Public Health Act, 1875, to partially repeal, alter, or amend (1) the West Ham Corporation (Loans) Act, 1888, as amended by the West Ham Corporation Act, 1893, and the West Ham Order, 1897, so as to enable the Corporation, subject to certain conditions and restrictions, to exercise any statutory borrowing powers they may possess for any purpose, either wholly or partially, by using for such purpose any money for the time being forming part of the Loans Funds not required for the payment of dividends on Corporation stock; (2) the Provisional Order relating to West Ham, confirmed by the Local Government Board's Provisional Orders Confirmation (No. 11) Act. 1891, so as to enable the Corporation to borrow, with the sanction of the Local Government Board, additional moneys for the purpose of that order; (3) the West Ham Local Board Extension of Powers Act, 1884, so as to enable the Corporation to carry into effect an agreement for the leasing of certain lands acquired by them under that Act for the purpose of constructing a pumping station for sewage and other works, and to carry into effect such other arrangements with regard to lands of which the Council may from time to time be seized or possessed as the Local Government Board may sanction; (4) the West Ham Corporation (Improvements) Act, 1888, and the West Ham Corporation Act, 1893, as amended by the West Ham Order (No. 2), 1895, and the West Ham Corporation Acts of 1898 and 1900, so as to enable the Corporation to utilise certain lands at Canning Town, which they were by the Act of 1888 authorised to acquire for sewage purposes for the erection thereon of an electrical generating station for lighting and tramways purposes in substitution for lands authorised by the Acts of 1898 and 1900 to be used for these purposes, and so as to confer on the Corporation other powers in regard to the use or disposal of lands acquired under the Acts of 1888 and 1893.

PERSONAL.

Mr. H. Simpson has been re-elected Inspector of Nuisances for Worksop.

Mr. H. W. Chadwick has been appointed Surveyor for the Town Council of Ormskirk.

Dr. P. L. Benson has been reappointed Medical Officer of Health for the Rural District of Buckingham.

Dr. R. W. Pierce, of Chelmsford, has been appointed Medical Officer of Health for Woking at a salary of £80.

Mr. R. W. Marshall, of Fenton, has been appointed Surveyor and Sanitary Inspector for the Urban District of Uttoxeter.

Mr. Robert Reid, Burgh Surveyor, has been appointed Clerk of Works for the additional sewerage works at Rattray.

Dr. Dickman has been appointed Medical Officer of Health for the Worthing Urban District, in succession to Dr. Higginson.

Dr. Anningson has been reappointed Medical Officer, and Mr. Archer Inspector of Nuisances for the rural district of St. Ives.

The salary of Mr. J. M'Combe, the manager of the electric tramways, has been increased from £300 to £350 per annum.

Mr. J. S. Hendry, of West Bromwich, has been engaged to carry out a sewerage extension scheme at Cannock, involving an expenditure of £25,000.

Mr. Rowland Plumbe, F.R.I.B.A., has resigned the office of District Surveyor, under the London Building Act, for the District Surveyorship of West Hampstead.

The Local Government Board has sanctioned the reappointment of Mr. C. Gander as Sanitary Inspector and Highway Surveyor for the rural district of Alcester.

Dr. E. R. Morgan and Dr. Trafford Mitchell have been re-elected Medical Officers under the Llangyfelagh District Council, at salaries of £60 and £100 per annum respectively.

Mr. John S. Lloyd, M.R.C.V.S., has been appointed Veterinary Inspector for the City of Sheffield, at a salary of £300 per annum, rising by advances of £25 per annum to £400.

Mr. Oswald Graham, late Clerk of Works to the Electric Lighting Committee at Middlesbrough, has been appointed to a similar position under the Urban District Council of Whitby.

At the special meeting of the Shoreditch Borough Council, the Mayor, Mr. H. E. Kershaw, J.P., presented on behalf of the Council a handsomely-framed illuminated vellum to Mr. Joseph Cox, in recognition of his able, courteous, and impartial conduct of the business of the Vestry during his term of office as chairman of the last local Vestry.

The Parish Council of Langley, near Slough, have appointed a lady as Inspector of Slaughter-houses for the destruction of horses. She will be paid by fees, and as Langley is the centre of the horse-slaughtering industry for a very wide and populous district, the office is a lucrative one. This, we think, is one of the positions not fitted for a woman to take. It may be sentimental on our part, but, from personal experience, we distinctly assert that the slaughter-house is no place for a woman.

Mr. Ernest A. Borg, assistant Borough Surveyor of Margate, has been granted an honorarium of thirty guineas for preparing parliamentary plans, making water survey, &c., in connection with the proposed new water supply scheme for the borough.

The Leamington Town Council has accepted the resignation of Mr. Henry Consett Passman, who for over a quarter of a century has occupied the position of Town Clerk of the borough. Mr. Passman, who went to Leamington from Stafford, contends that during his period of office he has saved Leamington £25,000 by his successes in litigation. On one occasion, when the assets of the Corporation were sequestered, he kept the town going by paying its expenses out of his own pocket until sequestration was removed. He was first Town Clerk of the borough on incorporation. Previously he was clerk to the Leamington Local Board. Mr. Passman's resignation, which is due to advancing age, has been accepted with regret.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2171.—Cleansing Houses of Persons in Receipt of Parish Relief.—"Inspector" writes:—"In my district there are many houses occupied by poor persons who live alone and are in receipt of parish relief. In many cases these persons are infirm and ill in bed, and the occupier is unable to cleanse the house, or pay for same being done. Can we call upon the owner, or is the Relieving Officer responsible?"

Answer.—The Relieving Officer may, and in our opinion, should, in most of such cases, where the persons who are infirm and unable to cleanse the houses which they occupy, obtain an additional allowance from the Guardians for the purpose of securing the cleansing of such houses. If the Infectious Diseases (Prevention) Act, 1890, has been adopted in the district, the Local Authority may, if they so deem necessary, on the report of their Medical Officer of Health, cleanse and disinfect the premises at the cost of the Authority.

2172.—Sanitary Institute Congress: Place and Date not Fixed.—"W. S." writes:—"For the information of your readers will you kindly say whether there is likely to be any Science Congress in connection with the Sanitary Institute during the present year, and if so, where it is to be held?"

Answer.—From inquiries we have made we learn that the Sanitary Institute has not yet decided whether a Congress is to be held during the present year under their auspices, and that no place has yet been selected as to where the next Congress will be held.

2173.—Surveyor and Gas Engineer: Appointment; Salary.—"Inquirer" writes:—"Kindly let me know if it is usual for the Town Surveyor to be Gas and Water Engineer also? And what would be the average salary of such an officer under an Urban Council having a population of 20,000 inhabitants?"

Answer.—Our correspondent omitted to enclose us his name and address, and his reply has been delayed in consequence. These particulars are necessary as a guarantee of good faith, though we make the rule, which is invariable, that the names of querists will not be published or divulged. With particular reference to his query, we have to state that the Surveyor to an Urban Authority is frequently also Gas and Water Engineer, and such a combination in the hands of a competent officer is beneficial and economical to the Local Authority. As to the average salary payable to such an officer, this we are unable to ascertain, but it should not be less than from £400 to £600.

2174.—Public Health (London) Act, 1891: Qualifications of Sanitary Inspectors.—"S. B. T." writes:—"Could you clear up a point as to which I am in doubt with respect to the qualifications of Inspectors under the Public Health (London) Act, 1891? I have the certificate of the Sanitary Institute, dated July 29th, 1899, also plumbers' certificate. In a recent advertisement in The Sanitary Record, it says: Any person who passed the examination of the Sanitary Institute previous to December 31st, 1899, would be on the register of the Sanitary Inspectors' Examination Board. Now, at the foot my certificate it states: 'This certificate is not registered under the Public Health (London) Act, 1891.' Does this debar me from entering for London appointments? I may add that I was not an Inspector previous to 1895."

Answer.—The querist is under a misapprehension. Certificates granted prior to December 31st, 1898—not 1899—by the Sanitary Institute are recognised as qualifying candidates for the office of Sanitary Inspector under the Public Health (London) Act, 1891. The querist is therefore not qualified, and it will be necessary for him to pass the examination of the Sanitary Inspectors' Examination Board before he can be qualified for appointment as a Sanitary Inspector in London.

2175.—Alumino-Ferric for Precipitation of Sewage.—"A. B. C." writes:—(1) "What is the best means of mixing alumino-ferric with raw sewage in proper proportions? (2) How much raw sewage is precipitated by one gallon of saturated solution of the alumino-ferric, such solution containing 7½ lb. in one gallon?"

Answer.—(1) Inasmuch as the sewage of every town differs so considerably in character, it is inadvisable and foolish to apply any chemicals such as Spence's alumino-ferric except after obtaining an analysis of the sewage and the advice of a chemist or that of the manufacturers, Messrs. Peter Spence and Sons, Limited, Manchester, as to the proper proportions to be used. We advise that this course be followed by the querist. (2) We are unable to advise with the information before us. The querist might usefully communicate with the firm named, who would give him all the information possible.

2176.—Building after Notice of Disapproval of Plans. "Y. R." writes:—"My Council recently disapproved the plans of a proposed school. Notice of disapproval was given the architect without specifying in particular the various reasons for disapproval. The architect, however, says that they are not out of order, and is proceeding with the building. No surface drainage is provided for, as shown by Bye-law 60 (see bye-laws herewith), and no window is shown in the water-closet. The drains are shown as proposed to be connected to an existing drain, but the surveyor contends that they should be shown to be connected to a proposed sewer in the road. The Council have decided to prosecute the architect. Will you please advise whether the Council will be enabled to succeed, and what should be their next step?"

Answer.—The notice of disapproval to be effective must be given within a month of the date of deposit of the plans. If the

BETHNAL GREEN, LONDON, E.

plans were in conformity with the bye-laws the builder might proceed although the plans were disapproved, but he must give the notices as to intending to commence the erection of the building and also before commencing to cover up the foundations, and if these have not been sent proceedings may be taken against him. The Council must determine against whom proceedings are to be taken—the architect, builder, or the proprietors of the school. The Council may also, if any bye-laws are contravened in the erection of the building, sue for penalties for breach of the bye-laws, and may, after giving notice to the builder under Clause 99 of the bye-laws, pull down so much of the building as contravenes the bye-laws. The non-provision of surface drainage, and non-provision of windows in the water-closets are contraventions of the bye-laws, and the Authority will be able to succeed in proceedings for a recovery of the penalties, if in the execution of the work these are not carried out. The Council are not enabled to disapprove the plans, because the drainage is not carried directly into the road as suggested, and this should not be pressed.

2177.—Powers of Sanitary Authorities. — "Student" writes:—"What powers as to the abatement of nuisances have (1) Urban Sanitary Authorities, (2) Rural Sanitary Authorities, (3) Factory Inspectors, under the Public Health Act, 1875? Also under the Factory and Workshop Acts?"

Answer.—We are unable to find space in this column for answers to ordinary questions set at Inspectors' examinations. It is evident the querist has not read any book on the Public Health Acts. He should procure Reid's "Practical Sanitation," price 6s., and study the subject with the aid of an experienced "coach," such as advertise in our pages. He might also obtain "Model Answers to Questions set by the Sanitary Institute," price 2s. 2d. Either of the books may be obtained from the office of this journal, but the new edition of the latter is not yet ready.

2178.—Overcrowding of Dwelling-houses.—"Inspector" writes:—(1) "If the occupants of a house are so numerous that a cubic space of 300 cubic feet is not allowed in the bedrooms, can the tenant claim to use the house, kitchen, or other rooms as sleeping-rooms before a conviction can be obtained? (2) Can you find a case in point? (3) Am I right in assuming that a house is overcrowded when the number of the occupiers is greater than would allow 300 cubic feet for each adult in the bedroom?"

Answer.—(1) If rooms in the house, such as the kitchen, &c., are actually used as sleeping-rooms, the tenant is entitled to use such. But rooms not so used cannot be counted as cubic space in estimating as to whether overcrowding exists. (2) No. (3) There is no statutory provision that 300 cubic feet must be allowed for each adult. It has, however, come to be accepted as a standard, and the evidence of the Medical Officer of Health will be essential in order to support this. The Authority would not obtain a conviction for overcrowding the bedrooms if the occupier proves that other rooms are used as sleeping-rooms, and that in the aggregate a cubic space of more than 300 cubic feet is provided.

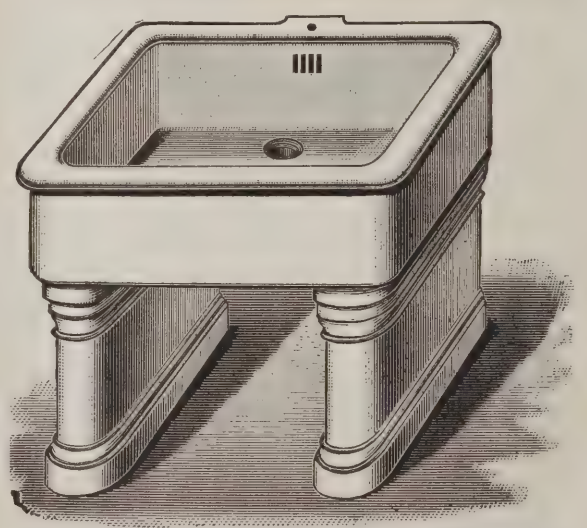
CRAIG'S WHITE GLAZED FIRE-CLAY SINKS

On White Glazed Fire-Clay Supports.

In appearance nearly equal to Porcelain, which they greatly excel in strength and durability. Admirably adapted for use in Kitchens, Sculleries, Butlers' Pantries, Laboratories, &c. Extensively used in houses of the better class, and in many important buildings throughout the country during the last thirty years.

Adopted by H. M. Board of Works, H.M. Commissioners of Prisons, &c.

Awarded First Prize Medal by the Sanitary Institute of Great Britain



J. & .M CRAIG, Ltd., KILMARNOCK

GENERAL SUGGESTIONS AS TO BACTERIAL TREATMENT ON BACTERIAL LINES.*

By W. J. Dibdin and C. Chambers Smith.

Without entering into questions of detail, the principles which are now generally accepted as necessary to be observed in regard to processes for the purification of sewage may be shortly summarised as, first, the removal of the coarse solid matters held in suspension; and, secondly, the treatment of the finely-divided organic matters left in suspension, as well as impurities in solution by utilising the agency of the living organisms known as bacteria.

These objects may be accomplished in various ways, viz., the solid matters may be stopped by means of gratings or screens of various degrees of fineness, and the refuse so collected dug into ground; or it may be allowed to subside in the usual precipitating tanks and removed from thence and pressed as in the old methods of chemical treatment; or it may be arrested and liquefied in detritus tanks; or, again, it may be run on to very coarse-grained bacteria beds; or, lastly, by the method adopted at Exeter, and now followed largely elsewhere, by means of which the solids are allowed to collect in tanks containing twenty-four hours' flow of sewage, and there undergo putrefactive decomposition, with the result that the settled sewage so obtained may be finally purified on fine-grained bacteria beds.

The particular method of applying the settled sewage to these beds has undergone considerable discussion. The original and largely employed method is to fill them, and after they have been standing full and quiescent for about two hours to empty them at not too rapid a pace. It has been proposed, however, to modify this method by the adoption of rotating sprinklers, and it is reported that excellent results have been obtained by these. Whichever method be adopted (and doubtless all are good, according to local circumstances) the final result is that the sewage is effectually purified without the use of chemicals or the daily production of that foul abomination technically known as "sludge."

One of the chief features which calls for attention in connection with these beds is in respect to the arrangements proposed for causing them to work automatically. It is not necessary here to refer further to the different schemes than to mention the most prominent, viz., those of Mr. Cameron, Mr. Adams, and Messrs. Mather and Platt, and many others, whilst modification of the sprinklers commonly used in breweries and for watering gardens seem to be doing good work, as already mentioned.

Amongst the first considerations to be borne in mind in regard to all new schemes or modifications of old ones are the requirements of the Local Government Board. It has for long past been the fashion to decry the action of this Board, and the authors do not pretend that some of their requirements may not be open to criticism; but whilst this may or may not be the case, it is, under present conditions, useless to beat the air with vain regrets. The only thing which may be usefully considered is the best way of complying with the conditions laid down by the Board, which, rightly or wrongly, is the governing Authority whose decisions must be obeyed.

These requirements are, shortly, that provision must be made in all new schemes submitted for their approval, for the treatment of storm water up to five times the normal dry-weather flow of the sewage; that, according to circumstances, during rain periods, either two or three times the normal dry weather flow must be treated as if it was all normal sewage, the remainder up to the total volume of six times the normal flow being separately treated as storm water; and that provision must also be made for treating all bacterial effluents, however obtained, on land, at the rate of one acre for each 30,000 gallons of liquid, except in the case of storm water, which may be put on land at the rate of 500 gallons per yard superficial.

When commencing the consideration of a new scheme the first points to ascertain are the essential features in regard to quantity of sewage; possibility of carrying the sewage to the outfall works by gravitation, or necessity for pumping, land available, character of the sewage, and suitability for treatment by any particular method, the quantity and nature of any manufacturing waste liquors to be admitted into the sewers.

In many cases this latter consideration will have but little weight, but in others it becomes a very serious question. For instance, it may be proposed to initiate a scheme for a small town or village, in which there is a large or comparatively large, factory producing foul waste liquors equal to four or five times the volume of sewage produced by the whole of the population draining into the scheme. In such a case it may fairly be argued that the extra burden which would be thrown upon the ratepayers by the inclusion of such a volume of foul water into the scheme is unjust, and that the manufacturers should bear the cost of its purification, especially as it has to be borne in mind that when once the Local Authorities have consented to receive this liquor into their sewers they will be unable to rid themselves of the burden, no matter what may be the difficulty and cost experienced in its purification at their works.

In certain cases where the nature and extent of the polluting trade refuse is not of an undue character and admittedly is not of an increasing quantity beyond the normal increase of the population, there will be no objection to admitting it into the system. Gasworks refuse liquor, for instance, generally bears a definite ratio to the normal volume of sewage, and when diluted to that extent no objection is taken to its presence therein, but in those cases where the manufacturing refuse liquor exceeds either by reason of quality or quantity the sewage proper, or forms an unduly large part thereof, it should not be received unless under special circumstances, and with a clear understanding on the part of all concerned.

One of the most difficult problems in connection with the question of the admission of trade refuse into sewers is that in regard to the effect on an industry by reason of the too heavy burden imposed by the cost of a suitable scheme for purifying the liquid in question which the owners of the factory are entitled by prescriptive right to turn into a stream. This is one of those points which require all the knowledge, tact, and patience of all concerned. Factory owners are quite as much alive to the pollution caused by the refuse from the factory as any River Inspector, but they have also to bear in mind the other side of the question, viz., the far-reaching effect of the work going on in the factory, the number of mouths fed by the distribution of the weekly wages, as well as many similar economic considerations. Many such difficulties have been successfully met, and many more will be gradually overcome in time, but one of the worst methods of settling or rather unsettling the difficulty, is to rush into law suits before exhausting all other methods.

With regard to the legal aspect of the question, it is provided by Sect. 7 of the Rivers Pollution Prevention Act, 1876, that "every Sanitary Authority having sewers under their control shall give facilities for enabling manufacturers within their district to carry the liquids proceeding from their factories or manufacturing processes into such sewers, provided that this section shall not extend to compel any Sanitary or other Local Authority to admit into their sewers any

* Paper read at the Conference of Municipal and County Engineers, Building Trades Exhibition, Agricultural Hall, April 26th, 1901.

liquid which would prejudicially affect such sewers or the disposal by sale, application to land or otherwise of the sewage matter conveyed along such sewers or which would, from its temperature or otherwise be injurious from a sanitary point of view. Provided also that no Sanitary Authority shall be required to give such facilities as aforesaid where the sewers of such Authority are only sufficient for the requirements of their district, nor where such facilities would interfere with any order of any court of competent jurisdiction respecting the sewage of such Authority."

It may be observed that in the first clause of the section it is suggested that although the word "shall" is peremptory, the learned editor of "Lumley's Public Health Acts" suggests that the Authority must have some discretion in the matter, and that they will doubtless be entitled to require some payment for the facility and to impose conditions and regulations as to the communications to be made with the sewers.

The provisions of Sections 16 and 17 of the Public Health Acts Amendment Act, 1890, bear on the admission of injurious matter into sewers, Section 16 providing that, "It shall not be lawful for any person to throw or suffer to be thrown or to pass into any sewer of a Local Authority or any drain communicating therewith any matter or substance by which the free flow of sewage or surface or storm water may be interfered with, or by which any such sewer or drain may be injured—penalty for contravention £10, and daily penalty of 20s.; and Sec. 17 enacts that "every person who turns or permits to enter into any sewer of a Local Authority or any drain communicating therewith (*a*) any chemical refuse (*b*) any waste steam, condensing water, heated water, or other liquid (such water or other liquid being of a higher temperature than 110 deg. Fah.) which either alone or in combination with sewage causes a nuisance or is dangerous to health, shall be liable to a penalty not exceeding £10, and to a daily penalty not exceeding £5. The Local Authority by any of their officers, either generally or specially authorised in that behalf in writing, may enter any premises for the purpose of examining whether the provisions of this section are being contravened, and a justice's order may be obtained if admission be refused. A person is not liable to a penalty for an offence under this section until the Local Authority have given him notice of the provision of this section. In other words, the Local Authority must give notice to an offender, and wait seven days to see if the necessary steps are taken to stop the cause of the complaint.

Under the Rivers Pollution Prevention Act, 1876, Sec. 8, the duty of instituting proceedings for pollution of streams was vested in Sanitary Authorities, but as such Authorities were generally the chief offenders, the Act was practically a dead letter until the Local Government Act, 1888, came into force, which invested County Councils with power to enforce the provisions of the Act as regards pollution. Many of such County Councils have also obtained additional power in Acts promoted by them, and Rivers Conservancy Boards have also been created, which have obtained stringent powers by Act of Parliament to restrain the pollution of streams. Section 17 of the Public Health Act, 1875, prohibits Local Authorities from discharging unpurified sewage into streams, and Section 69 of the same Act provides for Local Authorities taking proceedings for pollution of streams where such pollution is caused by sewage, but not by manufacturing effluents.

The following cases decided in the superior Courts may be usefully cited with regard to the admission of trade refuse into sewers:—

Drainage of manufacturing premises: Cutting off communication with sewers: Injunction: Public Health Act, 1875, Section 21.—In Eastwood Brothers, Limited, *v.* Henley Urban District Council (Chancery Division—Mr. Justice Byrne, April 9th, 1900) the plaintiffs, who were woollen and worsted manufacturers, sought an injunction to prevent the Council from cutting-off the connection between the drain receiving the liquids proceeding from the plaintiffs' mills and the public sewers. The injunction asked for was granted. Mr. Justice Byrne, in giving judgment, said: The plaintiffs' predecessors in title had a right to cause their drain to empty into the sewer of the Local Authority, and the plaintiffs have a right to continue so to cause their drain to empty into the same sewer, under Sec. 21 of the Public Health Act, 1875. Having regard to the circumstances under which the connection of the plaintiffs' drain with the defendants' sewer was originally made, and to the length of time during which the state of things so initiated has continued, I am of opinion that I ought to hold, as I do, that the connection was duly and lawfully made. The plaintiffs' predecessors were, and they now are, entitled to empty through their drain, into the sewer in question, not merely sewage matter, but manufacturing effluents—see Peebles *v.* Oswaldwistle Urban District Council, 1897, 1 Q.B., 384, which was reversed, but not on any point material to the present case. Under these circumstances the plaintiffs are, in my judgment, entitled to an injunction to restrain the defendants from cutting off, as they threatened to do, the communication between the plaintiffs' drain and the defendants' sewer—see, among other cases, Attorney-General *v.* Clerkenwell Vestry, 1891, 3 Chap., 527, and the cases there cited. Having regard to the provisions of Section 16 of the Rivers Pollution Prevention Act, 1876, I do not think that Section 7 of the Act gives power to the defendants to stop up the communication in question, even if it had been proved beyond question (as it has not, in fact, been proved) that the liquid discharged from the drain into the sewer would prejudicially affect the disposal by application to land or otherwise of the sewage matter conveyed along the sewer. The defendants may or may not be entitled to some other remedy against the plaintiffs in respect of the effluent discharged into the sewer. I express no opinion upon the point, which does not arise in this action, but I am of opinion that the plaintiffs are entitled to an injunction to restrain interruption of the communication of the drain with sewer. (See report in the *Surveyor*, April 27th, 1900, page 457.)

Sewage disposal: Effluents from tannery: Rivers Pollution Prevention Act, 1876, *Sec.* 7.—In the Attorney-General and Sevenoaks Urban District Council *v.* Whitmore (Queen's Bench Division, Mr. Justice Matthew sitting with an Assessor, Mr. Baldwin Latham, C.E., July 24th, 1900), the Court had to decide between two sets of expert witnesses. The defendants were the owners of a tannery in the parish of Edenbridge, and the Council claimed an injunction to restrain them from causing or permitting the effluents from their tannery to flow into the sewers of the Council, on the ground that the effluents were of so offensive and dangerous a character that they caused the effluent flowing from the Council's sewage farm into the river Eden to be a nuisance to, and injurious to the health of, the inhabitants of the parish of Edenbridge and the persons living near the river Eden. The defendants contended that the Council were bound to continue the admission into their sewers of the effluents from the tannery, and that the nuisance, if any, was caused by the inefficient state and unskilful management of the sewage farm; and they alleged that the tannery effluents were as capable of being dealt with by bacterial treatment as ordinary sewage, if the sewage farm were properly managed. The Council further contended that the tannery effluents contained free alkalinity to an extent which rendered them a liquid which would "prejudicially affect the application to land" of the sewage matter conveyed along their sewers, within the meaning of Section 7 of the Rivers Pollution Act, 1876 (39 and 40 Vic., C. 75),

and that consequently they were not compelled to receive such effluents into their sewers. It appeared that in 1875, when the Local Authority constructed a system of sewers leading to settling tanks and thence into the river Eden, the defendants had received a notice requiring them to connect their tannery with the sewers of the Local Authority, which they had done. In 1886 the present system of sewerage was constructed; and before connecting themselves with the new system the defendants, at the request and under the supervision of the sanitary authority, erected settling tanks on their own premises. Upon the completion of this work the Sanitary Authority agreed to admit and admitted the tannery effluents into their sewers. Dr. Voelcker and Mr. Thudichum were called on behalf of the Council, and stated that in their opinion the tannery effluent contained alkalinity to so great a degree that a liquid resulted which prejudicially affected the application to land of the sewage matters conveyed by the plaintiffs' sewers.

Mr. Strachan, Mr. Frank Scudder, and Mr. Santo Crimp, who were witnesses for the defendants, were of opinion that the effluent of the tannery, in which no chemicals other than vegetable acids and lime were used in no way prejudicially affected the application of the sewage to land, inasmuch as a considerable quantity of the free alkalinity was reduced by carbonic acid from the household sewage in the plaintiffs' sewers and the settling tanks at the sewage farm. They also considered that, owing to the sewage farm being on a clay soil and underdrained, the sewage matter found its way through the cracks in the soil into the underdrains, unaffected by the bacteria on the surface, and so passed in its crude state into the river. The assessor, Mr. Baldwin Latham, having made a report to the learned judge, his Lordship, in delivering judgment, stated that he was not convinced by the evidence given on behalf of the plaintiffs that he relied and acted upon the evidence of the witnesses for the defendants. He gave judgment for the defendants, with costs.

(See report in the *Surveyor*, August 10th, 1900, page 178.)

In Southall Norwood Urban District Council *v.* Middlesex County Council, January 21st, 1901, Q.B.D., 65, J.P., 215, the appellants had been ordered by justices acting in and for the petty sessional division of Brentford in Middlesex to discontinue the flow or passage of offensive or injurious matter from their farm or works into the river Brent. The respondents, the Middlesex County Council, had instituted proceedings before the magistrates in respect to their having caused and suffered sewage and other offensive and injurious matter to pass from their farms into the river. It appeared that in 1894 the predecessors in title of the Council having been required to grant facilities for carrying the liquids and effluents from a margarine factory in their district into their sewers, entered into an agreement to receive such liquids on condition that the owner of the factory should erect and maintain in good working order at his own expense, to the reasonable satisfaction of the Board, on his own land, settling tanks for the purpose of extracting so far as might be practicable all solids, fat, or fatty matters in suspension from the said liquids and effluents.

The appellants in 1898 referred to arbitration the question as to whether the settling tanks were sufficient, and some alterations were required to be carried out as from and by the award of the arbitrator. Notwithstanding this, however, the liquids and effluent discharged from the factory contained so much solid and fatty matter which was objectionable and difficult to treat, and which liquids and effluents when mixed with the sewage in the appellants' sewers rendered it difficult for the appellants to effectually purify the sewage, the effect of which was to so clog the land in the appellants' farm that it became saturated with sewage and rendered the farm unable to effectually filter the sewage from the appellants' district. The Middlesex County Council gave the appellants notice under their Act of 1898 to discontinue the flow of sewage into the river Brent, and the appellants contended that they had not under the circumstances stated, caused, or suffered sewage or other offensive or injurious matter to flow or pass into the said river within the meaning of Section 13 of the Middlesex County Council Act, 1898. The Court (Phillimore and Bruce, J.J.) held that it was the appellants who caused or suffered to pass or flow sewage or other injurious matter into the river within Sec. 13 of the said Act. Phillimore, J., said, "I rest my judgment upon this: having taken over this place from their predecessors in title, the Council collect the sewage on this place, treat it and discharge it through an effluent, and *primâ facie* the Council has to excuse itself from discharging a filthy effluent into the river. The excuse it offers is not sufficient. Either it ought not to have made an improvident contract, or having got a contract, it should see the contract is properly carried out, and either not receive the stuff it is not bound to receive, or take the trouble of enforcing its rights under the award and have the stuff purified; or finally, if it must receive the stuff in its present state, it ought to take other steps on the sewage farm to purify the effluent. I therefore think there must be judgment for the respondents."

These judgments show the danger of admitting factory waste into sewers unless very stringent precautions are taken to ensure their being subjected to preliminary efficient treatment. Once they are admitted, the responsibility for their purification rests upon the Local Authority concerned. As will be seen from the cases cited, the question becomes one of conflicting evidence with the result of a judgment which may or may not be based on facts of the case. It will be of the greatest interest to hear of any definite instance of the effectual purification of a caustic alkaline liquid by means of land treatment.

The lesson to be derived from these facts is most important at the present time, when Local Authorities are being so generally required by manufacturers to admit their factory wastes into their public sewers, and it is on this account, and also because it has been to a considerable extent neglected, that we have dealt somewhat fully on this side of the question, and suggest that Local Authorities should be careful to safeguard themselves, so far as possible, in the first instance before agreeing to the admission of liquids such as those in question into the sewers.

Stockton.—Dr. W. H. Blandford, the Medical Officer of Health to the Stockton District Council, has just issued his annual report on the health of the district. In it he regrets that the death roll has increased from 13·9 per thousand in 1899 to 15·5 per thousand. The doctor remarks that there has been a steady increase in the death-rate since 1896, and commenting upon this he says:—"It may be caused by the large influx of the population into the populous parts of the district where buildings are being rapidly erected, without streets being completed, and all in a state of transition, to a little overcrowding, to a want of cleanliness in the people and their homes; also careless scavenging and the lack of careful and systematic inspection. The deaths in young children have very seriously increased throughout the district, and in Billingham district, out of eighty-one deaths, fifty-one were in children under five years of age, or 62·9 per cent. of the whole deaths. A large number of children died just immediately after birth. This I very much regret, as it shows a want of health in the parents. The high infantile death-rate in certain sections of the population is in a very great measure preventable, and I believe if every care and attention were given these fragile lives many might be saved.

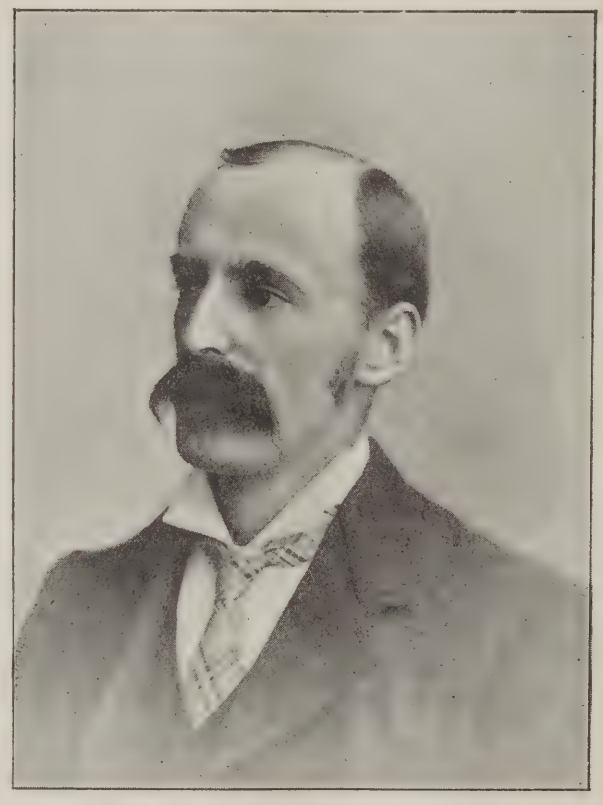
Coming Municipal Men.

XX.—MR. GEO. BALL, Assoc. M. Inst. C.E.,

Engineer & Surveyor, Bexhill Urban District Council.

The subject of the present article, after serving a regular term of articles under the firm of Messrs. Hunter and Carr, Architects and Surveyors, Middlesbrough, entered the office of the late Mr. David Petch, Architect and Surveyor, Scarborough, as chief assistant, which position he held for six years. During that time he designed and carried out many important residences, hotels, and schools, and laid out building estates, new roads, and sewers.

Having a desire to follow more closely the works appertaining to sanitary engineering, he applied for the position of assistant in the Borough Engineer's office, Scarborough (under the late Mr. Joseph Petch, C.E.), and was appointed out of many applications. In due course he succeeded to the position as Deputy Borough Engineer, under the present Borough Engineer, Mr. W. S. Smith, Assoc. M. Inst. C.E.



MR. GEO. BALL.

During the fourteen years Mr. Ball held this position he was engaged in the more important works of municipal and sanitary engineering, including several sections of the main sewerage scheme of the borough, including over a mile of outfall sewers, 5ft. diameter, with sea defence works, costing over £6900, in addition to the laying out of 600 acres of building estate, the property of the Corporation, the erection of public lavatories and conveniences, a new hospital (small-pox), and sea defence works. He also assisted in preparing a scheme for a marine drive and sea wall (1200 yards long), drainage and laying out the undercliff and gardens, at a cost of over £50,000, and prepared the parliamentary plans for the extension of this scheme round the Headland to the junction of the South Parade, at an estimated cost of £70,000. These works are now in progress, and, when completed, will form a marine drive about 2¼ miles in length, connecting the north and south bays of the town. A further improvement, carried out from the designs of Mr. Ball, was the effectual securing of about 2½ acres of very precipitous and sliding cliffs, by constructing a heavy retaining wall at the base, with concrete groynes and deep underdraining, with rubbish abutments and embankments, laying out paths, erections of shelters, lavatories, and public conveniences, in the undercliff. This was a very difficult undertaking, what appeared a huge shipping and wasting cliff, about 150ft. above sea-level, was converted into a "Garden by the Sea."

Other work of some importance was the widening and improving the gradients of the main approaches into the town, what were mere country lanes were formed into main roads, 50ft. and others 75ft. in width. The expenditure on these works was upwards of £20,000.

In June, 1897, he was selected out of 160 applications for the position of Engineer and Surveyor to the Bexhill Urban District Council, and since that period the town has grown probably more rapidly than any other health resort round the coast, the population having increased from 1891 (5026), 1900 (12,340).

Many building estates have consequently been laid out and developed, which means a very large amount of work in the Surveyor's department.

During the past four years contracts have been carried out for £20,000 in private street works, and ten others are in hand. Mr. Ball has laid out a new cemetery, costing over £3300; a new sewage scheme, consisting of 4½ miles of pipe sewers, varying from 24in. to 9in. diam., with sewage lift and storm-water overflow of cast iron pipes 3ft. diameter, towards low-water mark, at a cost of over £9500; new public urinals and plans for underground lavatories, road improvements, and greatly improved the main roads and district roads, of which there are over thirty-six miles. Many miles of paving, caused by the installation of the electric light in the town, have had to be reinstated, and Mr. Ball is now engaged on a scheme for the widening and improving of nearly three miles of highways. Also a marine promenade, carriage drives, laying out and improving about 12½ acres of land for a Public Park and Recreation Grounds.

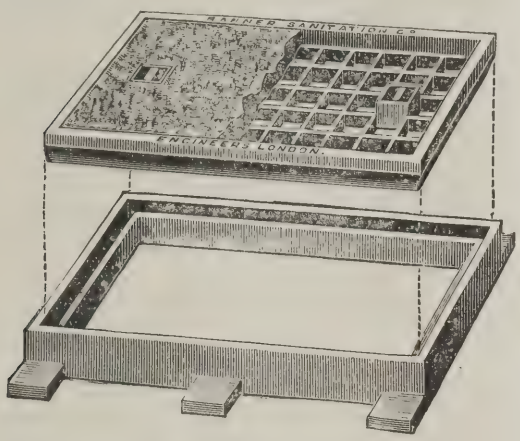
In March, 1895, he was elected an Assoc. M. Inst. C.E., and in October, 1886, he successfully passed the examination of the Incorporated Association of Municipal and County Engineers and Surveyors, qualifying as a graduate, being admitted a member of the Association in 1897.

The Loughborough Town Council has resolved that application be made to the Local Government Board for its sanction to the raising of loans for the several purposes and to the amounts following, that is to say: Purchase of land for sanitary depôt, Allsopp's-lane, Nottingham-road, £250; road construction, Granby-street, extension of Frederick-street, £186; street making and sewerage, Meadow-lane, £613 7s.; kerbing, Forest-road, Emmanuel Church to the Woodbrook, £118; flagging, Nottingham-road, £189 3s.; flagging, Baxter-gate, £251 11s.; flagging, Market-place, £230 15s.; flagging, Devonshire-square, £179 14s. 6d.; street improvement, raising of road for flood prevention, Forest-road, £481 9s. 6d.; total, £2500.

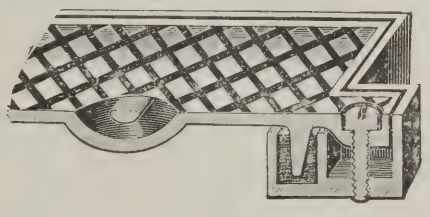
BUILDING TRADES EXHIBITION.

[Second Notice.]

Drainage appliances and the metallic woven stair treads are exhibited by the Banner Sanitation Company, of Craven-street, Strand. Our attention was called to the rustless cast iron air-tight covers and frames for manholes, cesspools, wells, and rainwater tanks, which are also prepared for concrete or tile fittings, as shown with

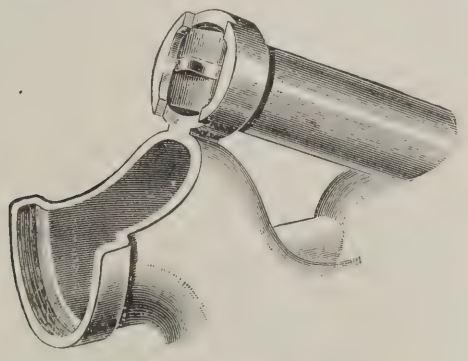


lugs for keying to concrete or tar paving. The next illustration gives a very safe and simple method of locking covers to frames. The gun-metal screw bolts being outside the seal, all danger from drain air passing



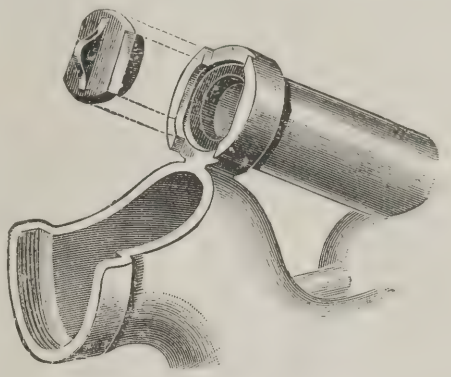
through bolt holes is avoided, as will be seen on glancing at the section of locking arrangement. The only change in Banner's Self-acting "rapid" drain testers is that for glass a metal tube has been substituted. The "Volcano" smoke machine was on view, and its principle described once again.

"B.P." at a distance recalls the hero of Mafeking, but on close acquaintance the "B.P." of Messrs. John Knowles and Co. has really to do with the patent "back-pressure" safety stopper. There were many features on the



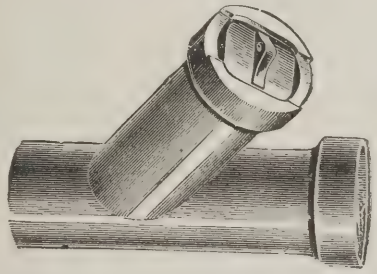
B.P. Stopper in situ.

stand, but the "B.P." we hasten to describe and illustrate for the benefit of all and sundry in the sanitary world. In ordinary practice the ordinary bitumen-lined stopper, as applied to interceptors, is liable to be forced out by the back pressure of gas or sewage, and when the stopper is forced out it drops into the trap and blocks the drain. The illustrations depict a change, and the "B.P." stopper will commend itself to experts for general use in



B.P. Stopper Removed.

inspection eyes, cleansing arms, and branch connections of main sewers. This stopper is recommended to civil engineers in the construction of main drainage schemes. As a matter of fact various devices have been resorted to by engineers to make an effective temporary stopper in the junction arms which are laid at intervals in the



B.P. Stopper Applied to Junction for Prospective Use.

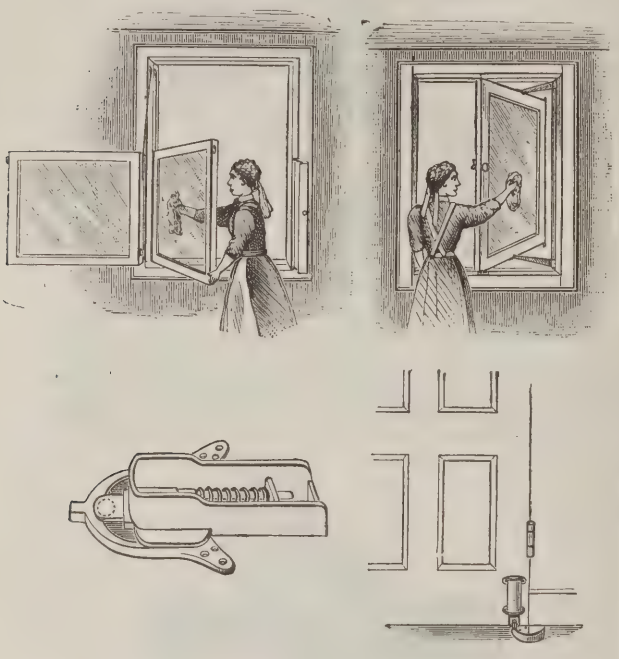
main drain, for the purpose of subsequent house connections. But these devices have been more or less unsatisfactory. The use of the "B.P." stopper will change this, and prevent any nuisance. It has the great advantage of being easily removed, and the pipe from the house drain inserted, without the slighest disturbance of the drain. It can be supplied for a purpose of this kind at almost the same price as the ordinary bitumen-lined stopper.

Mintons, of Farringdon-avenue, have a neat arrangement for the display of wall tiles. In one section are bird panels, with raised outline and painted in coloured glasses, after Leon V. Solon, displaying excellent work. Then their panels of fish, and pheasant, and partridge by Wright; and figure panels in slight relief L. V. Solon. This is a charming salon by itself.

Wire wall ties and flat wire ties were exhibited by the "Warrington" Bond-Iron Syndicate (of Brewery-street, Manchester). We examined specimens of the cavity and solid ties, and came to the conclusion that, properly placed, they would be immovable. It is not necessary to cut or chip bricks, as the tie can be bent to fit into the course. These bond-irons appear to be in general use in England, Wales, and Scotland.

Models are greatly in evidence at Islington, and Mr. J. C. Moore (secretary of Moore's Patents Company) provides several, which we illustrate. When windows are fitted with the patent vertical sliding sash the servant is safe. When the sashes are at the bottom they are always hinged, but the person inside can by moving a handle turn them inside to paint, repair, or clean the outside, and then replace them as easily as an ordinary door is opened and closed, without steps, poles,

or risk of accident. By moving a catch in the inside of a casement window with the finger when the sash is open, the outside will turn inside for cleaning. Another novelty is Moore's two-way door spring and hinge. They are screwed on the floor, without cutting a hole for them, and on the bottom of the door. They have a screw adjustment—operated by an ordinary turn-screw or screw-driver without removing anything — to suit



them to heavy or light doors, and the bearing part runs in oil. The door will stand full open or will close gently, and when closed no draught will open it. The one-way door springs are screwed in a vertical position near the bottom hinge on an ordinary hinged door. These novelties cannot be too widely known.

An American firm, the Standard Sanitary Manufacturing Company, of Pittsburg, and 22, Holborn-viaduct, exhibit a fine display of baths, lavatories, and w.c. seats. These finely finished appliances well repaid inspection, and although the firm is new to us, the excellence of their wares is such that we feel certain they have "come to stay."

Mr. Walter E. Mason (late A. Mason and Sons), of Horwich, had an attractive collection of sanitary specialities on view. Mr. Mason makes enamelled fireclay ware, and specimens of his handiwork were to be seen in the basins, ranges, closets, tanks, cisterns, and sinks exhibited. The baths were well finished, and the examples of decorative marbling were greatly admired. The full-size working models of urinals, lavatories, and closets were quite a feature in Mr. Mason's display, and no doubt proved "a lesson without words" to many of the visitors.

The Westminster Sanitary Works occupy a large space, and have placed their specialities to the best advantage. Messrs. Davis and Bennett have partitioned off their mosaic floors and tiled wall linings from lavatory ranges in marble or porcelain. The marble and porcelain safes for closets and baths are attractively shown, as well as their special cast iron drainage fittings.

A model of the handsome arched doorway in tawny terra-cotta to 11, York-street, W., now in course of erection, was quite an effective feature in the space occupied by Messrs. Joseph Cliff and Sons, of London and Leeds. The stand was tastefully arranged, and artistic vases, in which palms rested, were disposed in different parts to the best advantage. The firm manage to intersperse their imperial porcelain baths, sinks, and lavatories, with patent hanging tiles, "dovetailed-keyed" bricks, majolica fireplace, and Grip patent wall tiles. Tiltman's patent partition bricks and scum troughs for swimming baths attracted considerable attention.

Cellar flaps and coal plates are a speciality of the St. Pancras Ironworks Company. We lifted one of the flaps with ease, but the other was beyond our strength or skill. Their prismatic and other pavement lights are a feature which should not escape the notice of contractors, who wish to shed light in American darkness. The models of forge works would attract artistic blacksmiths; and the models of staircases would not be overlooked by perplexed architects.

Sanitary ware was tastefully shown in the corner space of the third row by Messrs. Broad and Co., of Paddington. Specialities of various kinds were on view, and the manner in which the bends, pipes, channels, gully traps, manhole covers, and bricks were displayed, commanded the admiration of the visitor. Manhole chambers fitted up with white enamel channels, &c., were inspected; and also tiles in various colours and patterns for wall work. We also noted specially the adamantine clinkers and channels for stable paving, as being exceedingly useful, while the encaustic and paving tiles for floor work caught our eye. The patent scullery sink is made in white enamel and cone-glazed stoneware. In this sink the ordinary grating is replaced by a deep perforated cup, made of stout tinned copper, into which tea leaves and other solid matters fall, and are at once intercepted without choking the outlet, which is furnished with brass grating as a further precaution against solids passing into the waste pipe. The copper strainer is loose, it can be lifted out and emptied as required. This sink should please housewives.

The Midland Stoneware Pipe Co. (of which Mr. F. H. Brook is managing director) had a small but representative exhibit of sanitary pipes, chimney tops, sewer pipes and bricks, gullies, syphons, &c. Mr. Brook also exhibited specimens of the manufactures of other houses for whom he is sole agent in London, such as John Carr and Sons, Lumley Brick Company, Wm. Mobberley, and the Sussex Brick Company.

Mr. Peter Wood, of West Bromwich, exhibited samples of the famous annealed blue bricks, including plinths, bull-noses, sploys, and pavings of every description. The manner in which various specialities were arranged left nothing to be desired.

Messrs. S. and E. Collier, of Reading, had a nicely-decorated stand, the red ware drain pipes being quite a feature. The entrance to an imaginary house at once showed the uses to which the bricks, garden edging tiles, roofing and wall tiles, finials, and other specialities could be applied. The terra-cotta designs were very pretty, and the mural tiles and panels exeedingly attractive. Altogether this stand provided a veritable object lesson to builders, sanitarians, and architects.

The introduction of daylight into dark buildings may be obtained by adopting electro-glazed Luxfer prisms. That is the claim made by the British Luxfer Prism Syndicate (of Hill-street, Finsbury), and in their attractive stand they put it to the proof. Specimens were shown of Luxfer rolled prismatic glass in various angles in sheets, and electro-glazed for warehouses and factories; and for canopies and skylights. The samples of best glass for decoration work and fire screens were very fine; while pavement lights, cellar flaps, and rolling lights were all displayed. The syndicate also make a very nice show in the fire-prevention section with their fire-resisting clear glass and Luxfer prisms. This stand attracted much attention.

(*To be continued.*)

NUISANCES AND METHODS OF INSPECTION.[1]

By J. Spottiswoode Cameron, M.B., B.Sc., M.O.H. Leeds.

NUISANCES AND INSANITARY CONDITIONS.

(*Continued from page* 353.)

The Public Health (Scotland) Act, 1867, is somewhat more precise in its definitions of a nuisance, and will require separate study by those holding or intending to hold appointments in Scotland.

In the 47th Section of the 1875 Act (which is a re-enactment of the first and second clauses of the 59th Section of the Public Health Act, 1848) certain offences are punishable by fine and cumulative penalty if committed or allowed to occur within an urban district. They are three, and may be remembered by the letter "s," "swine," "stagnant," "soakage."[7] The Section runs as follows:—"Any person who in any urban district (1) keeps any swine or pigstye in any dwelling-house, or so as to be a nuisance to any person; or (2) suffers any waste or stagnant water to remain in any cellar or place within any dwelling-house for twenty-four hours after written notice to him from the Urban Authority to remove the same; or (3) allows the contents of any water-closet, privy, or cesspool to overflow or soak therefrom, shall," &c.

Offences against any of these three Sub-sections are punishable in each case by a penalty not exceeding 40s., and a further penalty not exceeding 5s. a day if the offence is continued, and the law not permits but requires the Urban Authority to abate or cause to be abated every such nuisance and enables it to recover the expenses of so doing.[8]

While, therefore, the question of injury to health is the great moving power in the Public Health Act, it is not always necessary to prove that the nuisance complained of has actually caused injury to health. In the Section just quoted (47) "any swine or pigstye so kept as to be a nuisance" must be dealt with by the Authority. But it is only the Urban Authority which is thus compelled to deal promptly with the nuisance apart from the question of injury to health. In the 91st Section (the third "p") the animal must have been kept so as to be a nuisance or injurious to health.

At first sight it might appear that the word "or" implies an alternative, viz., a thing that is a nuisance, whether injurious to health or not, and (2) a thing which is injurious to health. But such is not quite the meaning assigned by the Courts to the words used in the Section. These words are the same as those employed in the Nuisance Removal Act of 1855.[9] Under this Act it was held, in an action by the Great Western Railway Company against Bishop, that a nuisance which was created upon a highway by water percolating through the railway bridge and dropping on to the road beneath was not "a nuisance or injurious to health," because that expression was to be read in the sense of a nuisance injurious to health.

This decision was subsequently explained by Justice Stephen. His definition of the words "a nuisance or injurious to health" was as follows:—"Anything that would diminish the comfort of life, though not injurious to health, and anything which would, in fact, injure the health." And he explained that in the previous case the Court abstained from bringing within the purview of the Nuisance Removal Act a nuisance of an entirely different kind from the nuisance the legislative intended to deal with.

I pause here to remind you again that all the three "p's," "premises," "pools," "pigs," in Section 91 of the 1875 Act have to be "nuisances or injurious to health," and that the same is true of the fourth sub-section,[10] accumulations; while the fifth Sub-section deals with overcrowding only when it is dangerous or injurious to health. In the sixth, vapours and dust have to be "a nuisance or injurious to" health, and the overcrowding has to be "dangerous or injurious to health."

Pigs seem to have been a constant source of trouble to the community. We saw earlier that Blackstone specially instances them amongst his list of nuisances, that the Public Health Act, 1848,[11] specially required their removal, when a nuisance, in towns, and when within town dwellings, even without the proof of a nuisance, and that the Nuisance Removal Act, 1855, enabled Authorities to deal with these animals anywhere if "a nuisance or injurious to health," or according to Mr. Justice Stephens, in such a state as to "diminish the comfort of life, even though not injurious to health."

Diminishing the comfort of life implies, perhaps, a considerable amount of annoyance, not probably such an inconvenience as would be suffered by a man passing half a field's length from a pigstye once a week on his way to business. Such could scarcely be said seriously to "diminish the comfort of his life." It is, therefore, necessary, in considering nuisances which cannot be dealt with as naturally or absolutely injurious to health, to take into account the degree of annoyance they are likely to occasion. A manure heap, for instance, against your garden wall might greatly interfere with your comfort and enjoyment of life, but a reasonable amount of manure placed upon a field and rapidly covered in might be considered by the Court as coming under the first proviso of the 91st Section as "an accumulation or deposit not kept longer than was necessary for the purposes of business or manufacture."[12] The distance from any dwelling or thoroughfare at which any accumulation was retained, and its size and the length of time for which it remained would enter into the calculation as to the degree of annoyance suffered by the community.

For it must be remembered that it is the duty of all public sanitary officials to protect the public health with the smallest amount of harassment to private interests. The public health must be their first consideration, but they must "do their spiriting gently." Shylock remarks: "You take my life when you do take the means whereby I live," and we must remember, even in guarding the public interest, that we must be careful not to destroy those trades and industries whereby people live. Hence there is need of judgment on the part of the inspector.

Judgment and discretion are especially necessary where the Urban Nuisance Inspector has to take action under the 49th Section of the Public Health Act, 1875.[13] This Section places it entirely at his discretion to serve a twenty-four hours' notice for the removal of a heap of manure, or similar filth, and if the order is not complied with, the Authority may remove, and sell, the same.[14]

---

[1] A lecture delivered in the Philosophical Hall, Leeds, April 13th, 1901.

[7] Should you have any objection to the use of the word "soakage" for the catch word for the third Sub-section, you may translate the word cesspool into the Yorkshire word "sump," when the three catch words would be "swine," "stagnant," "sump."

[8] It will be noted that the keeping of swine inside a house, or so as to be a nuisance to anyone, as well as the allowing of the contents of the sump, &c., to overflow is a punishable offence, even where no notice is served by the Authority. Notice must be given of stagnant water.

[9] 18 and 19 Vict. c. 121. Section 8 deals with the three "p's" and the first "c."

[10] Added to definition in Nuisance Removal Act, 1855, by Section 19 of Sanitary Act, 1866, 29 and 30 Vict., c. 90.

[11] Section 59 re-enacted in 1875, Section 47.

[12] This proviso does not prevent the issuing by the inspector of a peremptory notice for removal in an urban district, but it might weigh with the authority in enforcing the abatement under Section 49.

[13] A re-enactment of the 3rd and 4th clauses of the 59th Section of the Public Health Act, 1848.

[14] Much friction may often be avoided by getting the Authority to enforce the 50th Section, by means of which they may prescribe definite periods for the removal of stable and other kinds of refuse.

Such great powers must be administered gently, "'Tis excellent to have a giant's strength, but it is tyrannous to use it like a giant."

Take, for instance, a particular kind of nuisance exciting a good deal of interest at the present time, "the house unfit for human habitation." Such may be dealt with under the Housing of the Working Classes Act, 1890, a consolidation of previous Acts with considerable alteration. Restricting ourselves for the moment to the second part of this Act, it is provided that the Local Authority on a representation being made to them by one of their officers, if satisfied that any dwelling-house appears to them to be "so dangerous or injurious to health as to be unfit for habitation shall forthwith take proceedings against the owner or occupier for closing the dwelling-house under the enactments set out in the third schedule to this Act,"[15] which enactments are, for the provinces, the 91st, 94th, 95th, and 97th Sections of the Public Health Act, 1875.

These are nuisance sections simply, and the action of the Courts in dealing with proceedings taken Under the 97th Section will be watched with considerable interest. For the Act of 1890 goes on[16] to confer powers upon the Authority first to obtain from the magistrate a closing order, which closing order may be accompanied by compensation[17] from the owner to the tenant for disturbance and next, a closing order having been made, and not determined by a subsequent order "the Local Authority, if of opinion that the dwelling has not been rendered fit for human habitation and that the necessary steps are not being taken with all due diligence to render it so fit, and that the continuance of any building being or being part of the dwelling-house is dangerous or injurious to the health of the public, or of the inhabitants of the neighbouring dwelling-houses, shall pass a resolution that it is expedient to order the demolition of the building."[18]

The notice of such resolution is then served[19] upon the owner, who can appear before the Authority and if the Local Authority, having heard him, still consider demolition desirable they can make an order that the house shall be taken down within three months, or in default, do the work themselves.[20] There is, of course, an appeal to Quarter Sessions against the order for demolition.

One very important point—and it is a point the Authority in considering the question of demolition would have to take into account—would be whether or not the house was capable of being made habitable. Here one can see much conflict of testimony in the future. In regard to houses damp, delapidated, badly drained, there can be generally little or no doubt as to whether they are fit or unfit for habitation, but often these evils can be remedied.

If, however, the house in the opinion of the owner would not recoup him for the necessary expenditure and he accordingly fails to carry out the needed alterations, the question of demolition would then have to be taken into account. For there can be no doubt that an empty house in a delapidated condition is a source of danger, annoyance, and frequently of injury to the health of the neighbours.

But a still larger question is here opened up. There are houses so situated in such close entries or built of such porous material, that it is quite impossibe, at any cost, to make them fit to live in. These houses there would be no difficulty in most cases about closing, though probably Local Authorities would often hesitate about absolutely abolishing even such property without some compensation.

Especially is this latter difficulty likely to be felt where the house itself, structurally, is not very bad, where it is air-tight, water-tight, fairly free from damp, and where the chief defects are the want of sunlight and the want of fresh air—defects possibly quite as much due to the building of other houses in the neighbourhood, since the dwelling was first erected, as to any fault of the original owner. In such circumstances, it is not likely that Sanitary Authorities would frequently think of destroying houses of this kind without any compensation at all. About their power to do so there does not, however, seem to me to be much doubt, if the houses are at the same time a cause of injury or danger to the neighbourhood. It is perhaps fitter, however, that the Authority should have this power of demolishing without compensation, as it will enable them to treat with extortionate owners on much more favourable terms, and reasonable owners are not likely to be met by an elected body, many of whom are themselves property owners, in an unreasonable spirit.

The two things required for the power to demolish the house, are:—(1) That the house itself should be unhealthy, and (2) That it should be a cause of injury to those who live near. The soil, of course, remains vested in the owner. Provision is, however, made in the same Act for dealing with buildings which are simply obstructive, and in these cases the Authority can give reasonable compensation. The amount is to be settled in case of dispute by an arbitrator appointed by the Local Government Board, who has, if the building be a dwelling-house, to take into account, amongst other things, whether its demolition would not improve other property belonging to the same owner.

A very large number of houses in our great towns belong to the class of those which cannot be made habitable, but even in the slums a great deal can often be done by the removal of the worst offenders, by letting air and light into dark passages and yards, and by attention to the ordinary sanitary requirements of the houses left. It never does to forget that cheap houses have to be provided, and that it is better to live in a house not all that it ought to be than to have no house to live in at all. The rule should be to insist that new buildings come up to a high sanitary standard, and for existing buildings to require the removal of all causes of major nuisance.

(To be continued.)

---

15 Section 32.
16 Section 32, "It shall be the duty of every Local Authority if . . . to forthwith take proceedings . . . for closing the dwelling-houses."
17 Section 32 (3).
18 Section 33 (1)
19 Section 33 (2)
20 Section 33 (3) and (4) Section 34.

Kingsbridge.—Dr. W. H. Webb, in his annual report to Kingsbridge Urban District Council, stated there had been 52 births, a birth-rate of 16·6 per 1000, and 69 deaths, equal to 12·5 per 1000. Only one death had occured from zymotic disease, the death-rate being ·3, the lowest possible. The percentage of deaths of children under one year was 11·5, and under five 21. Out of 39 deaths, eight were of persons over 80, the oldest being 89; seven were from consumption, and four from cancer, the same as last year. No death had occurred from influenza, a marked immunity as compared with other rural districts. Altogether the death-rate was the lowest recorded. The birth-rate was 5·6 lower than the average for the past six years. Percentages of deaths in children were extremely satisfactory. During the year only one notification had been received of the existence of infectious diseases in the district, the case being one of erysipelas. What he might term the total absence of any notifiable infectious disease in the whole district was remarkable. During the present and past year here had been only one case of typhoid fever in the district, a fact which pointed out the great value of the attention which the sewers were now receiving, and also the wisdom of enforcing proper traps and connections to various tenements.

INSTITUTION OF CIVIL ENGINEERS.

THE "JAMES FORREST" LECTURE.

On Thursday last a large audience assembled in the Lecture Theatre of the Institution of Civil Engineers to listen to Professor Frank Clowes (chemist to the London County Council) deliver the "James Forrest" lecture. The subject chosen was

"CHEMISTRY IN ITS RELATION TO ENGINEERING."

The introductory portion showed the close connection between the chemist and the engineer, more particularly as invention and discovery advance. The methods of teaching at various colleges and universities were very fully reviewed; also the part chemistry plays in the manufacture of steel. The portions of the lecture of most interest to the municipal engineer were those referring to gas, water, and sewage. On the first of these topics Prof. Clowes said it was scarcely necessary to point out the absolute necessity of chemical knowledge and chemical advice to the gas engineer. The engineer who designs and superintends in use the plant for making the various forms of gaseous fuel which are required for heating and lighting purposes, requires to keep abreast of chemical progress in these departments, and he will be seriously handicapped if he endeavours to proceed unaided and unadvised by the chemist, and if his products are not frequently subjected to chemical examination.

The design and construction of waterworks is pre-eminently an engineering undertaking, and includes not only the provision of suitable borings, conduits, storage reservoirs, and pumping stations, but also of suitable and satisfactory filter beds when necessary. But here, again, if the health and requirements of the consumers of the water supply are to be properly considered, the chemist must determine the character of the water source from which the supply is to be derived. He must ascertain its relative purity during the different seasons, its behaviour in contact with leaden cisterns and service pipes, and the means of preventing any risk of the water becoming poisonous from contact with lead if the supply is soft, or of diminishing or preventing the waste of soap and the formation of boiler scale if the water is hard. He is also charged with the duty of constantly examining the water as it is supplied to consumers, in order to ascertain whether filtration is properly and efficiently carried out, whether the bacteriological condition of the supply is satisfactory, and to make sure that the water does not receive any constant or casual pollution on its way to the consumer. Hence, in the matter of water supply, both the engineer and the chemist find their respective but closely connected spheres of duty.

There is another direction in which the constant relation of chemistry to engineering, and in which the association of the chemist with the engineer must be maintained if success is to be secured and expensive failures are to be avoided. Neither the engineer nor the chemist, alone and unaided, is the proper person to deal with the disposal of the sewage of our towns. In the final stage of designing and constructing and maintaining the necessary works on the large scale, as well as in the construction of works on the earlier experimental scale, the engineer undoubtedly finds his necessary and natural sphere. But it must be remembered that the processes by which the purification of town sewage has been accomplished, and has been from time to time improved, have invariably been evolved, directly or indirectly, by the chemist, and depend on chemical investigation, checked by the results of chemical analysis. It should further be borne in mind that, when any process of treatment has been established on the large scale, the results of its working, as in the parallel cases of gasworks and waterworks, must be constantly checked by chemical examination of the products.

It is not sufficient to pronounce a sewage effluent to be satisfactory because it is clear and inoffensive as it issues from the purification works. When the sewage has been clarified, something has been accomplished it is true, and due credit should be given for the improvement. But it is often only necessary to subject such a clarified effluent to examination by ordinary processes of chemical analysis in order to learn that it is laden with dissolved impurities, which are at the moment invisible to the eye and inappreciable to the sense of smell. When this effluent is exposed for a short time to natural summer temperatures, or to artificial summer heat in the chemist's laboratory, it runs rapidly into foul putridity.

Such an effluent should manifestly not be looked upon as having undergone successful treatment, and should not be admitted into any ordinary watercourse. It will certainly deprive any stream into which it is discharged of its vital dissolved oxygen, and will therefore render fish life impossible. It will probably, either constantly or occasionally, cause the stream itself to become foul, since in the absence of dissolved oxygen these dissolved impurities rapidly undergo putrid changes. The mere examination of such an effluent by the ordinary senses will evidently be entirely misleading, and it is only by the chemical examination of the effluent that its true character will be made known. The frequently repeated chemical examination of effluents is necessary in order to ascertain that their condition is such as will not lead to the creation of nuisance or offence.

The tendency of those in charge of any process of sewage treatment, if they proceed without frequent information from and consultation with the chemist, is to be satisfied with an effluent discharge which is apparently, but not really, of a satisfactory character. When the clear but impure effluent leads to nuisance, the temptation is to proceed to the erection of large and costly plant either for the improvement of the existing process or for the application of some newer method of treatment. This expenditure may be undertaken before the additional plant or the newer method has been tried on a small scale and thoroughly tested under the supervision of the chemist. The expenditure thus incurred may accordingly lead to no good result, and the new venture may prove to be a failure as far as good results of purification are concerned. In the development on the large scale of a scheme of sewage treatment which shall be suitable for any particular centre, the engineer finds one of his most valued and important spheres, but he should undoubtedly associate himself with a chemical adviser in the early experimental stage of testing the suitability of the process; and after the scheme is in operation on the large scale he should secure the advantage of the co-operation of the chemist in constantly examining the true character of the effluent which is being produced, and in ascertaining its effect upon the watercourse into which it is being discharged.

In no application of chemical and engineering principles is the co-operation of chemist and engineer more necessary for the attainment of success than in securing the suitable purification of our town sewage. Such co-operation has enabled London, Manchester, and other large centres of population in recent years to carry out on an experimental scale most important trials of the natural or bacterial treatment of sewage, and has led to reports on this method being published which will probably become classical. This experimental work has led to considerable and valuable development and improvement of the bacterial method. There is now no doubt that this process can inexpensively dispose of a large proportion of the putrescible sediment or sewage sludge, and can render the effluent not only non-putrescible and

suitable for maintaining the life of fish, but even pure if necessary. The process is therefore destined to effect great reforms in our sewage-disposal problem and considerable improvements in the condition of our watercourses.

It should be understood that the purification thus effected is in the true sense of the term "natural." It is brought about by the extremely minute vegetable organisms, known as bacteria, which are present in vast numbers in the sewage itself. The bacteria present in the sewage only require to be placed under suitable conditions in order to exert their extraordinary purifying influence. It is therefore by agencies naturally present in the sewage that it is rendered inoffensive, or even, if necessary, pure. No extraneous artificial substance is added. The direction in which recent improvements are tending for effecting our sewage purification are in the direction of simplication, and are effected by allowing natural processes to have their freest and fullest play, instead of applying artificial mixtures of chemicals.

If the engineer co-operates with the chemist and physiologist by first appreciating and grasping these recent facts of natural treatment and then devising and adapting suitable plant for applying them on the large scale to our town sewage, he will be fulfilling his true function and will be applying the forces of Nature to the advantage of mankind. Manchester at present leads the van in this important movement, since it is constructing bacteria tanks and beds on the large scale; London, Leeds, and many other centres are feeling their way, and the speed with which the system is generally adopted will naturally be largely affected by the interest taken by our Sanitary Authorities in adopting the best methods of sewage purification. By the long and patient experimental investigation of this natural process of treatment results have now been obtained which admit of extended application, and the time has arrived when chemist and engineer may advantageously co-operate in carrying out natural schemes of sewage purification on larger and larger scales.

The lecture was repeated on Friday afternoon.

CONFERENCE ON THE HOUSING QUESTION.

On Monday last a number of representatives of the various Metropolitan Borough Councils—mostly Mayors, Town Clerks, Aldermen, and Councillors—attended in conference at the Islington Town Hall, at the invitation of the Mayor of Islington, to discuss the housing question. The Mayor, who was supported by Sir Albert Rollit, one of the parliamentary representatives of the borough, was himself called upon to preside. He briefly explained the situation in which the Borough Councils were placed by the Housing of the Working Classes Act. It was decided that the conference should confine itself entirely to matters of administration, and should not in any way attempt to interfere in matters with which Parliament was at present concerned.

A long discussion took place on the motion of Alderman Mills, of Islington, calling upon the conference to agree that, as the adoption of a certain section of the Act by the Borough Councils would lead to dual control and possibly to overlooking expenditure, it was desirable that some arrangement should be come to with the London County Council as to the respective spheres of action of that Council and of the Borough Councils. Other matters that were considered by the delegates were the undesirability of obtaining parliamentary powers to displace the working classes without at the same time making such arrangements for rehousing as would satisfy the Council of the borough concerned as well as the Central Authority; the demand for trains that should be run within a radius of twenty miles of London at a maximum return fare of twopence; that loans should be issued to the Local Authorities by the Government, for housing purposes, at a reduced rate of interest; that Borough Councils with land available within their boundaries should set to work to build houses; and that an understanding should be arrived at between the Borough Councils and the County Council as to the part the Borough Councils should take in promoting building schemes outside the County of London.

It was also suggested that, in view of the desirability of simultaneous action by the Borough Councils, the conference should be continued, the future meetings being held at the Town Hall of the city of Westminster, in Charing Cross-road.

THE NATIONAL REGISTRATION OF PLUMBERS.

A meeting of representatives of District Councils for the National Registration of Plumbers was held at the Guildhall on Wednesday week. Belfast, Birmingham, Bradford, Cardiff, Edinburgh, Glasgow, Leeds, Manchester, Nottingham, and Plymouth sent delegates, and reports were presented showing that since the Conference of Health and Water Authorities and Plumbers was held in Birmingham in October last, 2082 operative plumbers and 494 master plumbers had been registered, and that the applications for registration were so numerous that a vast number still remained to be dealt with.

On the motion of Dr. Williams, Medical Officer of Health, Plymouth, it was decided to increase the facilities for the examination of applicants.

Baillie Dick, chairman of the Health Committee, Glasgow, reported that with a view to encouraging the students attending the plumbing classes in the city, arrangements had been made for admitting specimens of their work in the industrial section of the Glasgow International Exhibition.

Various arrangements for securing the more systematic training of plumbers were discussed, and on the motion of Dr. Alfred Hill, Medical Officer of Health, Birmingham, it was resolved that apprenticeship should be encouraged in connection with the National Registration of Plumbers, and a special form of indenture for plumbers' apprentices, framed by the Plumbers' Apprenticeship Board of London, should be circulated for adoption throughout the kingdom.

Mr. Marchbank, Edinburgh, undertook to adapt the form to the requirements of Scotch law.

On the motion of Mr. Jenkins, plumber, of Cardiff, it was resolved to advertise the conditions of registration for persons now engaged in the plumbing trade.

On the motion of Mr. Westley, plumber, of Nottingham, it was resolved to extend the date for receiving these applications.

EXAMINATIONS IN PLUMBERS' WORK.

Examinations in practical workmanship under the Company's Graded Syllabus of Instruction were held on the 27th ult. in London at King's College, for students from Tottenham, Wandsworth, and Willesden; and the Regent-street and Battersea Polytechnics for students attending classes at those institutions; at the Rawlish Technical School, Wimbledon, for students at Wimbledon and Kingston; also at Accrington, Ashton-under Lyne, Brighton, Cheltenham, Chorley, Darlington, Devonport, Dundee, Dunfermline, Garston, Gateshead, Great Yarmouth, Jarrow-on-Tyne, Lancaster, Leeds, Newcastle-on-Tyne, Northampton, North Shields, Plymouth, Southport, South Shields, Swansea, Warrington, West Hartlepool; and an examination at Manchester Technical School for candidates for registration. The examiners were an equal number of master and operative plumbers at each place.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

There is some doubt, I believe, as to whether the Sanitary Institute will hold a Congress and Exhibition this year, but that younger and more pushful organisation, the Royal Institute of Public Health, are maturing arrangements for their annual Congress, which is to be held at Eastbourne, under the presidency of his Grace the Duke of Devonshire, from the 25th to the 30th July next. In connection with the Congress there will be a municipal engineering section, of which Mr. Gloyne, the Borough Engineer of Eastbourne, is the hon. secretary, and with his characteristic energy he is leaving no stone unturned to make it a success, and has issued circulars to members of the Association of Municipal Engineers inviting them to attend and to reply to his invitation. Surveyors who are not members of the Association will be admitted to the meetings, and Mr. Gloyne will, I know, gladly give them all the information he can on their writing him. I may assure surveyors who do not know Eastbourne or its people that they will be delighted to make their acquaintance, for Eastbourne is one of the best managed and most attractive of our southern sea-coast watering-places.

Claims for recovery of expenses incurred through extraordinary traffic on public highways are of very frequent occurrence now-a-days, and such claims are made under Sec. 23 of the Highways and Locomotives (Amendment) Act, 1878. It does not appear to be so generally known as should be the case, that this section is amended by Sec. 12 of the Locomotives Act, 1898. Under the former Act, a Local Authority could only recover from the person "by whose order the extraordinary traffic has been conducted," and this was the contractor only. But the Act of 1898 makes the expenses recoverable from the person "by or in consequence of whose order" it is conducted, which means that the Local Authority may now recover from the person who employs the contractors—a very useful provision not only to the advantage of haulage contractors, but also to Local Authorities. As some Local Authorities appear to have suffered in one or two actions through their unacquaintance with the Act of 1898, it is advisable that surveyors should make themselves familiar with it.

The manufacturers of steam motor-vans are continually making improvements to suit the requirements of Local Authorities for their adaptation for use for municipal purposes, such as for street watering, refuse removal, &c., and Messrs. Bayleys, Limited, of Newington-causeway, Southwark, London, are among the most progressive of these. They have just issued some useful circulars descriptive of the classes of motors manufactured by them, along with comparative estimates of the work and cost of same when carried out by a given number of horses and that of a motor-van. While these estimates are open to some criticism, they will be useful to my readers who might obtain copies for the use of their Local Authorities.

The Building Trades Exhibition of 1901, which is held every two years at the Agricultural Hall, closed on Saturday last. I learn that it was in every respect an eminently successful show, and beat all its predecessors. I am not sure that out of all the exhibits there was any one which struck the average municipal engineer as being especially novel or a departure from existing methods. Possibly this is due to the fact that we have arrived at such a high state of perfection in sanitation that further improvements are only possible at considerably increased cost of production, and as the cost of existing apparatus and appliances is as much as those who are called upon to pay will bear, additional departures at increased cost cannot be introduced so as to be profitable from a business point of view. Be that as it may, there was nothing which was especially original.

There were two or three exhibits which I might mention as possibly interesting to municipal engineers, viz., a new process for reproducing architects' and engineers' plans in photography, termed the "new black line process," which is a speciality of Messrs. Norton and Gregory, of 24, Westminster Palace-chambers, Victoria-street, Westminster, S.W., engineers' and architects' photographers. The reproduction is made on ordinary drawing—not special—paper as in the ferro-gallic process, and as the copies thus made are on stout paper and very closely resemble originals, there are scores of engineers who will prefer the new process.

Another object of interest to the draughtsman engineer is an engineer's drawing table, with a drawing-board mounted on a patent rest, which allows the board to be placed at any angle, and also to revolve, so that any part of the board may be brought to the draughtsman, thus avoiding the releasing of the paper from the board, or the draughtsman having to be so frequently altering his position. There is also an attachment at the bottom of the board for holding drawing pins, pencils, rubbers, &c. Both of the apparatus, *i.e.*, the drawing-board rest and the bottom attachment, may be obtained separately. The exhibitor was Mr. John P. White, the Pyghtle Works, Bedford.

One did not fail to notice that numerous firms are introducing materials for the construction of fireproof partition walls, adaptable also for bungalows and cottages in districts where the much-maligned "Model" Building Bye-laws have not yet been introduced, for the thickness of such material did not, so far as I remember, in any case exceed 2½in., and the cost ranged at from 4s. to 5s. per superficial yard. The evolution of a substitute for brick walls for cottage building is not yet.

I was interested in noticing that our friends Messrs. Ham, Baker, and Co., who are as personally popular, I believe, among municipal engineers as their manufactures are in every respect excellent, were showing amongst their numerous exhibits a "waste preventing" water-post for public drinking fountains and for stand-pipes such as are necessary in courtyards in towns and also in villages where water is not laid on to each house, but where a stand pipe fixed in a common yard is made available for from two up to thirty or forty houses.

Whether it be in public fountains or stand-pipes, such as those last named, the taps are continually, as every surveyor and water engineer knows, out of order, and the waste of water and consequent soakage on the roads is unreasonable, and a source of considerable annoyance.

By a skilful design these engineers have so arranged an apparatus for attachment to the supply pipe to a drinking fountain or stand-pipe that a specified quantity of water, say a half or a whole pint for a fountain, and two or three gallons for a stand-pipe, can only be drawn at a time. The arrangement is so ingenious, and meets such a demand that the sooner surveyors and water engineers make an acquaintance with it the better.

Sene

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

MAY 2, 1901.

RURAL COUNCILS AND SANITATION.

THE attitude of Rural District Councils towards sanitary improvements is a matter which appears to be exercising some concern at present. The *Times* recently indulged in a very trenchant criticism of these bodies, pointing out that the majority of their members were farmers, never a very progressive class, who regarded public expenditure on reforms such as the housing of the labourer as an unnecessary imposition. Much of the information which reaches us from the rural districts fully bears out this assumption. It is well known that although these Councils as Sanitary Authorities have power to prevent the erection of new cottages without satisfactory provision for water supply and drainage, they do not in practice freely exercise it. The reason is obvious to those acquainted with the idiosyncracies of the rural intellect. They are averse to being thought unduly interfering or encroaching upon their neighbours' privileges. And this diffidence not only retards reform, but results in untold trouble and increased outlay in the future. In this policy of delay the Councils are sufficiently aided and abetted by the Local Government Board to encourage persistence, and thus it is that the recommendations of their Medical Officers of Health are ignored. Occasionally they are forced to move by an outbreak of typhoid or diphtheria. But as a rule nothing is done that can possibly be avoided, and even when it is done, it is scamped. It is in regard to the housing problem more especially that these bodies want stirring up. Miss Cochrane has recently in our own columns shown how utterly deficient is the present accommodation in certain districts coming under her own purview, but there is every reason to suppose that the same conditions, with modifications, exist all over the country. In some instances wealthy landlords are found who make it their duty to see that the labourers on their estates are properly housed; but in other cases the owners are too impecunious, or profess to be, to embark upon what they would term an unremunerative outlay. The worst offender, however, is the small owner, who has invested his savings in cottage property, and who knows little of sanitary obligations, and cares less. These landlords generally possess sufficient influence over their tenants to make an appeal to the Sanitary Authority out of the question, and very often the matter is further complicated by the small owner himself being a member of that body.

It is much to be feared that this constitutes one reason at least why the Rural District Councils do not exercise their full powers in regard to existing unhealthy houses. As the *Times* remarks, "the difficulties in the way of such action are partly common to town and country alike, such as the question whether a public body can exercise the same supervision as individual owners, or whether it is economically desirable that it should compete with private building enterprise; and perhaps, it may be added, the deficient pressure of public opinion upon such matters as sanitation or overcrowding." But the main difficulty, after all, would appear to be in the individual constitution of the Councils themselves, and in the lack of education and enlightenment among their members, for it is hardly to be expected that a body composed of men who require to be educated up to modern ideas upon sanitation and house accommodation as much as their own labourers are likely to constitute in the aggregate a highly competent Sanitary Authority. But, it may be argued, what of the officials—the Medical Officer, for instance? Cannot they educate public opinion? On the whole, we believe they do, but how often do we

find their recommendation ignored, and their opinion counted as "fads" by the very bodies for whom they act? It has been suggested that, as regards housing, the provisions enabling the Sanitary Authority to act upon the report of the Medical Officer of Health should be made compulsory instead of only permissive; or that some executive authority should be invested in the Medical Officer himself. We have no quarrel with that; indeed, we believe that it would be an excellent thing; but until public opinion is moved strongly and the education of the community in these matters assumes a more progressive shape, we can hardly hope for the rural districts to fall in line with the more enlightened urban communities.

Results of the Census.

The complete census returns will take a considerable time to compile and analyse, but from such of them as have already been issued some instructive deductions may be made. In the first place, turning to the populations of the larger towns, an interesting comparison at once suggests itself with the populations as estimated by the Registrar-General prior to the taking of the census. These estimate were based on the census of the preceding decade, allowance being made for an increase in the population based mainly on the ratio of increase during the previous decennial period. In the framing of these estimates there is, of course, room for a considerable margin of error, which in its turn will naturally affect the birth, marriage, and death rates calculated on the estimated populations. Constancy or uniformity in the progress of any one town from year to year, or in one decennial period after another, is not to be expected, nor is it found. But, on the whole, the Registrar-General's calculations will be found not to be so very wide of the mark. The net result of the census will, however, involve a complete rectification of the birth, marriage, and death-rates as previously calculated. In some cases the rectification required will be considerable. Take, for example, such a town as Greenock. The estimate of the Registrar-General placed its population at 60,267; the actual number, consequent on an increase of commercial activity, is 67,681. The result is very materially to improve the death-rate of the town, the estimated rate of 214 deaths per ten thousand of population being reduced to 192. In other towns, where the increase of population has fallen short of the estimates, the mortality rates will have to be raised. And so, in like manner, the process of revision will have to be applied all over the country. Turning next to the country districts, the Census figures already to hand confirm the evidence from other sources with which we are but too familiar, of the steady drift of the rural population into the towns. The cities grow larger, not merely on account of the natural law of increase, but because they are steadily draining the country parishes of their inhabitants; the rural districts, on the other hand, instead of exhibiting signs of a healthy increase in numbers, are manifestly dwindling. From the point of view of the public health, apart from other social and economic considerations, the fact is one which can only be deplored. The country, after all, is the well-spring of the nation's life. It supplies the towns with fresh and healthy blood. It is impossible, therefore, to regard this steady depopulation of the country to swell the already overcrowded city populations except with feelings of concern, for the result must be in the long run to exercise an unfavourable influence on the health and development of the inhabitants of the towns.

The Opening of Glasgow Exhibition.

The opening of the Glasgow International Exhibition is an important event in the life of the city. It is intended to signalise the commencement of the new century, and no effort has been spared by the promoters to make the "show" worthy of the city's fair reputation. During the last year, however, the Executive must have been harassed with many anxieties, for during that period the health of the city has been singularly unfortunate, having passed through at least two very trying experiences. First of all there was the outbreak of plague last autumn. It was of the mildest description, and the efforts of the Sanitary Authorities to stamp it out were attended with complete success; but for the time, in the eyes of the country and of the world, Glasgow was an infected spot. Then this year came the small-pox epidemic. From its extent it was much more formidable, and for fully three months it has kept the officials of the Health Department on the stretch. Between 1700 and 1800 cases have been admitted to hospital, and about 230 deaths have taken place. The worst of it is over, but it is not by any means eradicated yet, for at the end of last week there were still 158 cases in hospital. A comparison, however, with the preceding weeks shows that the rate of decrease has been most satisfactory, and such as to justify the confidence of the Authorities that the disease, if not absolutely checked, is now well in hand, and on the fair way to complete elimination. The presence of small-pox in the city need not prove a deterrent to intending visitors to the Exhibition, for not only are the cases now occurring very few, but they are, as they have been during the whole course of the epidemic, drawn almost entirely from the East-end, at a distance of several miles from the site of the Exhibition. At the same time the facts must be looked in the face, and the possibility of the attendance of East-enders from the infected districts cannot be ignored. Glasgow has, however, manfully grappled with the work of stamping out the disease, as it did also in the case of the plague, and as both visitations have already cost the city an enormous sum, we should sincerely regret if the success of the Exhibition were to be injured by fear of small-pox. The Corporation have, by way of preparation for the crowds of visitors that are expected, completely re-organised their tramway service, and converted it to electrical traction. The inauguration of the electric system

took place last week. As the new installation is described as being the most important in the country, it will doubtless prove attractive to engineers and members of Local Authorities.

Better Housing in the Highlands.

Among the matters dealt with in the report of the Congested Districts Board for Scotland, which was issued as a parliamentary Blue-book the other day, is the question of better housing in the Highlands, for which, the Commissioners state, there is a growing desire. "The people are becoming more and more dissatisfied with uncomfortable, unhealthy dwelling-houses, and with the unpleasant surroundings too frequently still to be found in many parts of the crofting area." With this feeling the Board have every sympathy, and they consider it of importance that crofters should be encouraged to improve their dwellings. The crofters are quite destitute, however, of the necessary capital, and as the Board learned that in certain cases landed proprietors had successfully established funds out of which loans were granted for the purpose of improvements, the loans being repayable by instalments, they were desirous of adopting a similar scheme for the congested districts, but found, unfortunately, that this was beyond their statutory powers. They suggest, therefore, that their powers should be extended. Another respect in which an extension of powers seems necessary is with regard to the provision of hospital accommodation. In the poorer Highland districts the difficulty of securing suitable hospital accommodation is almost insuperable, and the need is great. The Lord Advocate was recently questioned on this subject in the House of Commons, and he indicated, in his reply, that the amendment of the Congested Districts Act for this and other purposes would receive his sympathetic consideration.

Child-life "Frittered Away."

We do not remember seeing anything more disheartening than the record of the waste of child-life given by Dr. Pilkington (M.O.H., Preston) in his annual report. He states that during the past year 250 children died out of every thousand born—a proportion considerably in excess of that reported in any of the other large towns, Blackburn coming next with 220. To this great mortality amongst the very young the high death-rate of Preston is mainly attributable, and whilst the general mortality has in late years satisfactorily improved, the infantile deaths have, on the contrary, increased. Among the causes for this high infantile death-rate there are mentioned early marriages among factory workers, and the general employment of mothers in mills, together with the dangers attendant upon the nursing-out system. "If even the child—as no doubt is frequently the case—receives kindly treatment and attention, and is not drugged with one of the many so-called 'soothing syrups,' it too often falls a victim to food unsuitable, ill-kept, or badly prepared; and this not only at the house where it is nursed during the daytime, but also at its own home, where, through mistaken kindness, and while yet a toothless infant, it is regaled with such things as shellfish, tripe, tinned salmon, and pig's feet." "There are in every large town," continues the report, "and probably always will be, a certain number of homes where the wonder is that any infant can survive its nursing period; but it is lamentable to see how in the houses of better-class operatives infantile life is frittered away, and this apparently from want of a little knowledge or of attention to ordinary precautions." And so it will go on until the mothers have a proper home-life. Far better to have a little less money and more comfort; and when the operatives realise this a stop will be put to the slaughter of the innocents in many of our large towns.

Making an Example.

Last week a case of considerable importance came before the Recorder at the Central Criminal Court. A butcher of Highgate was charged with giving a bribe to a servant of the Metropolitan Asylums Board, in order to obtain certain information as to the giving out of some tender forms. The facts brought out were:—The Board from time to time advertised for tenders for the supply of goods to the various hospitals under their care. The tenders were sent in on printed forms, which the Board supplied, keeping a list of those tradesmen to whom these forms were issued. The defendant was a contractor in an extensive way of business, and had supplied the Board from time to time. In October of last year tenders were again invited, and the defendant applied at the offices on the Embankment for a form. It was handed him by the principal messenger, and then defendant asked him if he would supply him with a copy of the list of tradesmen to whom these forms of tender had also been issued. This the messenger declined to do. Defendant asked him on other occasions, and finally met him at the Barnet Railway Station, and, renewing his request, said, "I will give you a fiver and a card on my tailor for a suit of clothes if it comes off." The officer again refused, and then reported the matter to the Board. Acting under their advice, he afterwards wrote to the defendant, making an appointment with him in the City. In company with a detective-inspector of the City Police, defendant was met at the Ludgate-hill Station, when he was handed the list of contractors he had asked for, and the messenger received £5. This was the offence complained of. The defence set up was that the defendant acted in ignorance of the law, but the Recorder would not accept this as an excuse, and inflicted a fine of £500. We can only hope that this heavy penalty will act as a warning to others, for seekers after undue advantages are by no means confined to butchers.

The City of London new M.O.H.

When it was known that Dr. William Collingridge intended to offer himself as a candidate for the position vacated by the decease of Dr. Sedgwick Saunders, it was generally

expected that he would be appointed Medical Officer for the City of London, and these expectations were fulfilled on Thursday last. When it came to voting, the only other one at all in the running was Dr. Waldo, who did such excellent work in Southwark before that district was merged into the new borough of Newington. Dr. Collingridge has well earned the promotion thus obtained. For twenty years he has fulfilled with infinite credit the onerous post of Medical Officer of the Port of London, a district extending from Teddington to the Nore, some seventy miles. Prior to receiving that appointment he had some experience on the Continent. He was but twenty-two years old when the Turco-Servian war broke out, and he went out to Belgrade as a volunteer surgeon, and at once went to the front to organise the hospitals for the Servian army. At the close of the war, Dr. Collingridge received the special thanks of King Milan, and was decorated with the Order of the Takova. In addition to attending to the duties of Port Medical Officer, Dr. Collingridge has devoted considerable time to volunteering, being attached to the Honourable Artillery Company and the Volunteer Medical Staff Corps, besides occupying other positions in connection with Army medical work. He has also shown practical sympathy with the St. John's Ambulance Association, and the Life-Saving Society. In 1897 he was appointed Milroy Lecturer to the Royal College of Physicians; in 1898, Examiner of State Medicine to the University of Cambridge, and he represented it last year at the International Congress of Hygiene at Paris. He is a member of nearly all the recognised health associations in the metropolis, and has written several books bearing on different phases of sanitary science.

THE NEED OF UNIVERSAL EDUCATION ON SANITARY MATTERS.

(*Continued from page* 358.)

Now what constitutes education on sanitary matters? I should say a knowledge of the necessary conditions that ensure good health, amongst which are the following:—(1) Plenty of light and sunshine; (2) pure air; (3) pure water; (4) cleanliness of person and surroundings; (5) proper food.

Light and sunshine.—What a blessed gift is sunshine, and how little some people seem to know that the sun is the world's purifier, or they would not shut it out of their houses by blinds, shades, and curtains just because fashion dictates such a practice. It may save the colour in their carpets and curtains, but they lose the colour from the faces of their children and themselves, and frequently pay the doctor the cost of many carpets. Light and sun, of course, are necessary to the life of both plants and animals; the destruction of the most dangerous disease germs has often been immediately accomplished by the powerful rays of the sun; whilst with its assistance plant life is able to take up the poisonous carbonic impurities expired by man, assimilate them in its own growth, and return the oxygen back to the air for our use again. If the public had better knowledge on this matter alone they would insist upon more parks and open spaces being provided in all our towns and cities, well supplied with plant and tree life to carry on such work for our common benefit. It is true that open spaces in the centre of a city are very costly; but if we go to enormous expense for space for commercial purposes, the gain to the health of thousands of people should be well worthy a similar outlay, which I am sure would be willingly paid for if the people were properly educated as to the individual and collective advantages to be derived from such breathing room. Let the aim of the householder be to have light and sunshine, if possible, freely admitted into every part and corner of our dwellings and business places. Especially let all sanitary fittings be open, and as far as practicable, so placed that light can get all round and underneath them, for dark places even in well-regulated households soon collect dirt and other accumulations, in which alone can disease germs exist and multiply around us.

Pure air.—The greatest essential to healthy life is an atmosphere containing its fair proportion of oxygen. This, however, is not always easy to obtain outside our buildings, let alone inside, on account of the many impurities from breathing, manufactures, the production of heat, light, and food, and general animal and vegetable decay. Simple lessons could be given of how the atmosphere of a room becomes contaminated by breathing alone, when repeatedly used without renovation; when the air we breathe, containing, say, 21 parts in the 100 of oxygen, is expired or returned to the air with but 16 parts of that element, the other five parts retained in the body being replaced by poisonous vapours. Imagine the effect of continually breathing such an atmosphere. The burning of ordinary gas inside a room has a most serious effect upon the atmosphere, for one large burner will take as much of the life-sustaining parts of the air as four adults, and replaces it by carbonic impurities most dangerous to human life. The value of electric lighting, from a health point of view, should also be thoroughly explained and impressed upon the people. The effects of impurities arising from manufactures, such as white lead works, chemical works, dye works, match making, and other similar industries, which all assist in reducing the vitalising quality of the atmosphere, are also great. A proper knowledge of these matters by those controlling such industries would enable them to use the best precautions in the interests of themselves, the community at large, and especially those they associate with, as many of these impurities are brought home on their clothes, which would with proper knowledge and care have been left behind.

If dirty air was as visible as dirty water, what a shock most of us would get! Such an illustration would do more for the science of ventilation than either talking or reading. If you offered a man a glass of dirty water to drink you would insult him, but try to keep him out of a place where he will breathe equally dirty air, and possibly he may insult you. I contend, therefore, that very much more could be and should be done in educating those in our schools, and the public generally, on the great importance of obtaining the purest air possible wherever we are.

Take the question of dust alone; how lightly people use the word, and at times with what contempt. We have all seen dust floating in the sun's rays, especially in dark places where narrow rays have penetrated; it takes the form of minute particles, many of which have an organic origin. Indeed, these organic impurities are always found in inhabited rooms, especially in sick rooms, being thrown off from the lungs and skin to a considerable extent. We are given some idea of this by a medical man, who informs us that a family of five persons occupying a room during the day continuously for twelve months would have produced something like 40 lb. of this organic matter in the year. Information of this kind should make us rather welcome the annual spring cleaning, than grumble and growl at the incon-

veniences usually attending it. Dust also contains other matter, such as portions of hair, cotton, and woollen fluff, coal, wood, and various living organisms; arsenic has even been found in the dust of rooms, possibly from the dye of cheap wall papers. Now this dust must be thoroughly cleared away; I mean burnt, not thrown outside the door to be blown in at the windows. As we boil our clothes, so let us burn dust, and destroy all harmful germs that may exist therein.

With regard to the dangers that exist in dust, the wealthy are just as indifferent and ignorant as the poorer classes, perhaps more so; they certainly have more places for accumulating it. The thick carpets and curtains, tops of wardrobes (which seem, as a rule, to be made for the express purpose of collecting dust), hollow moulded cornices and cornice poles, space under beds hidden by hangings, in lumber rooms, closets, and below stairs, and in many other corners I could mention, dust and dirt find secure hiding places. Indeed, some luxurious homes are furnished with no consideration for sanitation, and are practically prepared for the cultivation of disease germs.

If we turn to the homes of our poorer classes, where the sleeping and living room is often in one, the greatest care should be taken to keep such apartments as clear of dust as possible. Often the good wife being anxious to have things looking clean for her husband's return, disturbs the dust about the room by a hasty brush round, without opening doors or windows to allow a circulation through the room, with the result that it is flying about the room at the time of his entering. It is of no use stirring up dust to let it settle down again, it should be scrupulously collected and burnt.

Another source of danger is found in churches and halls by the accumulation of dust in the trenches provided for heating pipes; disease germs must at times find a breeding place amongst the dust below the hot pipes, which cannot be effectually cleansed. It is not unusual to see a person suffering from some lung or throat trouble expectorate down these gratings, with what risk to others can well be imagined by the instructed observer. With proper sanitary knowledge and conscientiousness, these things would not be tolerated for a moment.

Pure water.—We are fortunate in most of our towns in having an efficient and tolerably ample supply of water available, and laid into our homes, supplied at a moderate cost both for dietetic purposes and for cleansing. The position, however, usually given for the storage cistern in the house leaves much to be desired; nor does the average householder ever get an opportunity of seeing if it is clean or otherwise, unless he is called upon in the middle of the night to explore the false roof in order to hammer up a burst pipe. They are put into dark closets or dusty false roofs, where the air is stagnant; and this is the case frequently in really good class property. It has always been a matter of surprise to me that Sanitary Committees, before passing plans, do not insist upon a cistern room being provided, of proper dimensions, and lighted and well ventilated, and protected from dust and other foreign matter. Surely the position of our drinking supply is worthy of as much consideration as the position of our water-closets, and more so than many details which local officials stubbornly stand out for.

The question of filters is another item upon which better knowledge is much needed by the general public. I never go into a house or hotel where I find a filter without making inquiries respecting it; and my experience is that not 10 per cent. of those who use filters ever think that they will become absolutely filthy if not regularly cleaned and re-charged. I have frequently come across the old carbon filter with its charge cemented securely inside, which has been in use for periods varying from five to ten years without ever being cleansed or re-charged.

A little knowledge here would make it quite clear that if a filter is doing any good it must be abstracting the impurities from the water, which are being accumulated in it; otherwise it is letting the impurities pass through, in which case it is of no use at all. How often does the householder run off the water from his cistern which has been standing stagnant during the time he has been away on a holiday? Water bottles are frequently left without changing the water, and many other little domestic matters are neglected chiefly for want of the necessary knowledge of simple sanitary laws.

The water supply to outlying farms and country houses is frequently of very doubtful quality, and is responsible for the spread of fevers to an extent well known to Sanitary Authorities, yet the users of the water are often indifferent as to where it comes from. I remember staying at a farmhouse for some little time, at which I discovered some days after I had taken up my abode, that the main storage tank was simply sunk in the ground about half a mile from the farm, and it was a regular habit of the youngsters to go and have a dip in it during the hot days and sail their toy boats. I need hardly say that I made a somewhat strong protest, with the result that it was built up above ground and properly covered and protected. Both the farmer and his wife, to use their own language, merely expressed the remark that "They had ne'er gi'en it a thought."

(To be continued.)

The following meetings will be held on Wednesday, May 8th, 1901:—General Purposes and Finance Committee at 4 p.m., Election Committee at 5.15 p.m., Council Meeting at 7 p.m.

OBITUARY.

MR. W. SANTO CRIMP.

Our readers will deeply regret to learn of the decease of this well-known expert in sewage disposal. It took place on Sunday week at his residence in Kensington. A few weeks ago the deceased gentleman was at Leeds, when one morning he was seized with a shivering fit. He immediately returned home, but so far from recovering, was obliged to take to his bed. No improvement took place, and on Sunday week he succumbed to pneumonia. Mr. Santo Crimp was born in Devonshire, and was in the forty-ninth year of his age. It was in 1878 that his first important work was undertaken, being in that year appointed Resident Engineer to the Croydon Rural Sanitary Authority, to superintend the drainage of Merton, Morden, Mitcham, and Wallington. Two years later he was appointed Surveyor to the Wimbledon Local Board, a position he held for ten years with honour and credit to himself and considerable advantage to the district. During his period of service at Wimbledon he re-modelled the sewage farm and works, reconstructed a great portion of the main drainage, and constructed and laid out the extensions. He designed the lines on which the present station bridge is being built, and the fire station in High-street is another of his works. He also prepared a scheme to supply Wimbledon with chalk water from Woodmansterne.

In 1890 he became District Engineer under the London County Council, to which body he also rendered distinguished services. It was by his advice that the ends of the settling tanks at the London County Council outfall works were connected, enabling the services of forty men who had previously been engaged in cleaning them out to be dispensed with, while the amount of suspended matter extracted from the sewage was so greatly increased that additional sludge steamers had to be provided. It is consequently not too much to say that the improvement in the state of the Thames is in a great

measure due to the improvement in the treatment of London sewage effected by the advice of Mr. Crimp. He retained his office under the London County Council until 1895, when he resigned in order to enter into partnership with Messrs. E. Brough Taylor and G. Midgley Taylor, under the style of Messrs. Taylor, Son, and Crimp. He was a member of the firm at the time of his death. During his connection with the firm he was consulted by the Authorities of Glasgow, Cardiff, Leeds, and many other important provincial cities and towns, and at the time of his death was carrying out work for many of them.

In 1899 he went to Bombay, having been engaged by the Authorities there to advise as to the drainage of the town, and while in India was requested to advise upon the drainage of some twelve other cities and towns. He was acting as consulting engineer in regard to no fewer than six Bills at present before Parliament. As a member of the Institute of Civil Engineers, a Fellow of the Surveyors' Institute, and a Fellow of the Geological Institute he was greatly respected, while he had also obtained some reputation as an author of technical treatises. His papers on the ventilation of sewers and sludge pressing appear in the "Proceedings" of the Institute of Civil Engineers. They were entirely original, and the results of his research were recognised as so valuable that the methods advocated have since been universally adopted. His book on sewage disposal, though written prior to more recent developments of sewage treatment, is still regarded by many as a standard work on the question, and has gone into the third edition. Mr. Crimp's death, at the zenith of his professional career, will be a serious loss to the engineering world.

National Health Society.

OFFICIAL TRANSACTIONS.

Annual General Meeting. — The annual general meeting of the Society was held on Wednesday, April 24th, at 53, Berners-street. The report of the work for 1900 was read, and showed a considerable increase and advance in the work and influence of the Society. The Chairman, the Rev. Prebendary Ridgeway, drew particular attention to the marked success of the Society's students in obtaining public appointments as Sanitary Inspectors during the past year. Miss Louisa Twining, the veteran member of the Society, spoke of the present insanitary and unsatisfactory arrangements for the removal of dust and house refuse in London streets. Sir C. Thomas Dyke Acland, Bart., was elected Chairman of Council, and after the re-election of other officials, the proceedings closed with votes of thanks to all the hon. officials for their valuable assistance during the year. Amongst those present at the meeting were the Rev. Prebendary Ridgeway, Miss Louisa Twining, Sir C. Thomas Dyke Acland, Dr. Kenwood, Dr. Childs, Col. H. B. Hamilton, Mr. J. J. Vesey, Mr. Malcolm McWharrie, Dr. H. Willingham Gell, Dr. A. T. Schofield, Mrs. H. B. Hamilton, Mr. Lawrence Hall, Miss Christine Hall, &c. &c.

Appointments.—We have much pleasure in announcing the success of Miss Bevan in obtaining the appointment as Sanitary Inspector to the Borough of Camberwell. Miss Bevan was trained by the National Health Society, and passed the examination of the Sanitary Inspectors' Examination Board in January last. It will be remembered that several similar appointments have been gained by the Society's students during the past few months, so that this further success is a matter of great satisfaction to the Society. We have also to congratulate Miss Curwen on her appointment as Assistant Lecturer under the West Riding County Council.

ASSOCIATION OF NATIONAL HEALTH WORKERS.

Special attention is drawn to the very interesting series of lectures organised by the Association of National Health Workers, to be given at 53, Berners-street, during next week. In addition to those lectures mentioned in our last week's columns, Dr. Robert L. Bowles, M.D., F.R.C.P., has most kindly promised to give a lecture on "The Proper Management of the Physical Relations of the Tongue, Mouth, and Throat in Various States of Unconsciousness, such as Drowning, Apoplexy, Epilepsy, Convulsions, Bronchitis, Hæmoptysis, and in Paralysis from Accident, Concussion of the Brain, and Fractured Skull; Stertorous Breathing, Snoring, Opium Poisoning, Anæsthesia, Suffocation from Poisonous Gases, Syncope, &c.," on Thursday, May 9th, at 5.15 p.m. All members of the National Health Society are invited to attend these lectures.

Public Works.

SEWERAGE.

The Urban District Council of Altofts seeks to borrow £7000 for a drainage scheme.

A loan of £10,000 has been contracted for the new sewerage scheme at Lutterworth.

The Bradford-on-Avon Rural District Council is about to carry out the sewerage of Holt.

The Newtown Linsford Council has received sanction to a loan of £1950 for sewerage and sewage disposal.

The Alford Urban District Council has received the sanction of the Local Government Board to the borrowing of £9000 for sewage works.

Sanction has been obtained to the borrowing of £32,962 for the purpose of constructing sewers at Foleshill and Stoke, recently added to the city of Coventry.

The Works Committee of Dundee Town Council has accepted the tender of Mr. Charles Johnstone to construct the new sewer in Wellburn-street, Lochee, at a cost of £118 15s.

The Loughborough Town Council has resolved that application be made to the Local Government Board for sanction to borrow £613 for street making and the sewerage of Meadow Lane.

Lieut.-Colonel C. A. Smith, R.E., one of the Inspectors of the Local Government Board, opened an inquiry at Cotherstone last Thursday relative to the proposal to borrow £2650 for the drainage of the village.

The Totnes Town Council has resolved that, subject to the approval of the plans by the consulting engineer, tenders be invited for a new sewer in Victoria and Ticklemore streets. It was said there was an impression in the town that the sewerage scheme would be a failure, but that view was not shared by the Council.

Colonel W. Langton Coke held an inquiry at West Bridgford recently into an application by the Urban District Council for sanction to borrow £7423 for the purchase of land adjoining their sewage farm for purposes of a refuse destructor, sewage disposal, stabling, &c., and £1100 for works of sewage disposal.

A special meeting of the Borth Rural District Council was held last week to further consider the Local Government Board's letter in reference to the drainage of Borth. The Council directed the Clerk (Mr. Hugh Hughes) to ask the Central Board whether it required a scheme for the drainage of the whole area of Borth.

On Tuesday in last week the flats employed on the construction of Douglas sewer outfall were decorated with flags and bunting in celebration of the laying of the last pipe. The outfall is an important section of the scheme now being carried out for placing the sewering of this important watering-place in a thoroughly modern and scientifically approved condition. This section has been constructed by Messrs. John Aird and Co., London, and has taken over twelve months to build. The outlet is placed several hundred yards seaward of Conister Rock, so that all sewage may be carried out to sea. The full cost has not yet been made up.

Colonel C. H. Luard, R.E., Inspector to the Local Government Board, held an inquiry at Bredbury last week to inquire into the Urban Council's application for power to deviate from the scheme of sewerage sanctioned on the 14th August, 1899, and for which a loan of £7855 was sanctioned, and for sanction to borrow £6480. The object for which the loan is required is for sewers and construction of sewage disposal works at the rifle range, Lower Bredbury. The scheme for which sanction was applied had been reported to the Mersey and Irwell Joint Committee, who considered it an improvement on the scheme sanctioned. There was no opposition.

The Select Committee of the House of Commons, presided over by Mr. Fison, last week resumed consideration of the Cardiff Corporation Bill, which sought to empower the Corporation to construct new intercepting and other sewers. The petitioners were the Penarth Urban District Council, the Glamorgan County Council, the Taff Vale Railway Company, the Barry Railway Company, and the Llandaff and Dinas Powis Rural District Council. Early in the sitting there were signs of agreement, and the Committee adjourned on two occasions to facilitate consultation between counsel. The important point at issue was seen in a desire on behalf of the opponents to place upon the promoters the obligation to provide sewage capacity in the main sewer at the rate of 70 gallons per head of the population from time to time draining into the sewer. The Corporation argued that with such a proposal there was no finality whatever to the scheme. They submitted that they would provide sewage capacity to the extent of 4,500,000 gallons, this to be the final sewage capacity provided under the scheme, and which was calculated at 50 gallons per head of the population estimated at present at 60,000, with a prospective increase of 50 per cent. The Committee decided in favour of the preamble of the Bill upon the terms proposed by the Corporation, but whereas sixty years were asked for the repayment of loans, forty-five were granted. Clauses were introduced into the Bill giving protection to the Local Authorities for their roads and sewers, and permitting them to drain into the proposed new sewer where it passed through their districts on terms to be arranged, or, failing arrangement, as might be settled by arbitration.

WATER.

The Hyde Town Council requires £7500 on loan for additional water mains.

A company is being formed to supply London residents with rain or soft water for the bath at 2d. a gallon.

A waterworks scheme for Cricklade, in the Rural District of Cricklade and Wootton Bassett, is estimated to cost £7000.

The Yeovil (Without) Parish Council has already entered a protest against the increased water charges made by the Borough Council.

Mr. Meade-King held an inquiry recently into the St. Just District Council's application for sanction to a loan of £3483 for the water supply of St. Just Churchtown.

At a recent meeting of the Guildford Town Council it was reported that the Local Government Board had signified its approval of the loan for £1700 for works of water supply.

The Kelso Town Council has engaged Mr. Harry W. Taylor, A.M.I.C.E., of Newcastle-on-Tyne and Birmingham, to report upon the Burgh Waterworks, with a view to their extension.

At the annual meeting of the Brownhills Urban Council it was decided to authorise the South Staffordshire Company to extend their water mains at Norton Canes at a cost of £241 on the usual guarantee.

Notice has been given that the Manchester water rate will be laid at the next meeting of the City Council. It is proposed to levy a domestic water rate of 8d. (yielding £36,000) and a public rate of 1d. (yielding £13,000) the same as last year.

At a committee meeting of Dunoon Commissioners, it was agreed, after an acrimonious discussion lasting two hours, to practically adopt the late Water Committee's recommendation and to have two of Bell's filters laid down as an experiment at a cost of over £300 each.

A novel and excellent proposal is being considered in New York. It is to preserve the fresh water for drinking and cooking purposes exclusively, and to erect a system of stand pipes which will supply every house with an abundance of pure sea water for bathing, and flushing the drains and sewers and street sprinkling.

The St. Helens Water Committee recently had under consideration the special report of the Water Engineer, in which he urges the necessity of providing additional storage accommodation, the cost of the reservoir and connections being £22,700, and the land £1940, a total of £24,640. The Committee decided to have an additional reservoir.

A Local Government Board inquiry has been held at Rochford with reference to the appointment of the Rural District Council for power to borrow £25,000 for works of water supply for the contributory parishes of Hadleigh, Hawkwell, Hockley, Rayleigh, Rochford, South Benfleet special drainage district, including the construction of works in the parish of Thundersley.

The Accrington District Gas and Water Board, instead of raising the price of gas, has increased the water rents for the ensuing quarter. For the poorest class of houses the increase is 4d. per quarter and upwards. In the case of some publicans and beersellers the increase is 25 per cent. There is a great deal of grumbling about the new tax. Accrington, Church, Rishton, Great Harwood, and Clayton-le-Moors are affected by the increased price.

The fight over the Tees Water Bill did not end in the House of Commons Committee-room. A meeting of the riparian owners have decided to carry the opposition to the House of Lords, the General Purposes Committee of the Darlington Corporation passed a resolution to a similar effect, and it is very probable that other bodies who objected to the measure in the Commons will follow suit, notwithstanding the modification to which the Bill was subjected before it emerged from the Committee stage.

At a meeting of the Galston Town Council it was unanimously agreed to accept the offer of Mr. James Steel, contractor, Galston, amounting to £5408 1s. 6d., for the construction of new waterworks for the burgh, and that of Glenfield Company (Limited) Kilmarnock, for valves and other fittings, £79 5s. 6d. There were twelve tenders for the former and ten for the latter. Work is to be completed within twelve months. The supply of water is to be brought from near the same source as the Newmilns water supply, in which Galston at present shares.

A PAPER entitled "Researches on Moorland Waters, Part II.; On the Origin of the Combined Chlorine," by the borough analyst, Mr. W. Ackroyd, has been communicated to the Chemical Society of London, and will be printed in due course in the Society's "Proceedings." It deals with the water of Widdop, and the investigations relate to the fifty odd tons of salt contained in the reservoir, which is traced to the rainfall.

IN connection with the Glenfarg water district, the Finance Committee of the County Council is to recommend at the quarterly meeting that an agreement should be entered into between the trustees of Major-General Kirkland, of Wester Fordle, and the County Council on behalf of the Perth District Committee regarding the right of a supply of water from Lochel Blank Burn for the Glenfarg water district.

THE Wisbech Water Bill came before a Select Committee of the House of Lords on Tuesday in last week. The decision of the Committee was on all points in favour of the Waterworks Company. The Committee were of opinion that the charges for small gardens were not too high, and with respect to the charge for supply other than domestic, they did not see their way to diminish the company's charges, neither did they see any reason against the capital asked for by the company being raised. They were of opinion that the annual value should remain as at present. On Wednesday the Bill was taken *pro formâ*, and certain clauses upon which there was agreement the previous day were inserted.

THE Commissioner for Public Works at Adelaide has received information of the striking of a valuable supply of artesian water in the dry north-east. For some time boring has been proceeding on Yandama Creek, about forty miles east of the southern end of Lake Callabona, and artesian water was reached at a depth of 1566ft. At 1600ft. a strong flow was tapped, the fresh water rising to the surface at the rate of 20,000 gallons a day, and there is every prospect of a largely increased quantity being obtained by sinking a little deeper. The value of the supply is almost incalculable, because the locality was previously one of the driest in the State, and teams frequently were unable to travel for perhaps twelve miles at a time.

THE Commission under the Private Legislation Act met again last week to resume consideration of the Irvine Water Supply Extension Provisional Order. The Commissioners were Sir T. Gibson Carmichael, presiding, Lord Belhaven, and Sir Walter Thorburn, M.P. Mr. Wood was Clerk of Court, and Mr. Dundas, K.C., and Mr. Constable appeared for the promoters, and Mr. Salvesen, K.C., and Mr. Pitman, K.C., for the objectors, Ayr County Council and the Burgh of Saltcoats. Prior to the meeting of the Commission, a conference took place between the objectors and the promoters, the result of which that the objectors agreed to withdraw their opposition, in view of certain concessions by the promoters. Mr. Dundas explained that under the joint arrangement the rights of the traders under the priority clause in the 1881 Order would be conserved, as against traders outside the scope of those coming under the priority clause; that the limits of water supply under the Order should be the burghs of Irvine, Saltcoats, and Kilwinning, and all parts of the parishes of Irvine, Dundonald, Kilwinning, Stevenson, Ardrossan, and Draghorn, to which gravitation would permit the water to rise to. The order was also held to apply to any extensions of the burghs mentioned. It was also provided that the assessment under the Order should be levied in the respective areas in accordance with the amount of the rental. Some evidence was thereafter led with reference to compensation water, after which the Commission found the preamble proved, and the clauses were then adjusted.

IN view of immediately proceeding with the scheme for the augmentation of the Crieff water supply, at a special meeting of the Water Committee of the Town Council, the estimates for the supplying of piping were considered, and out of the four offers, the successful firm was Messrs. R. Laidlaw and Sons, ironfounders, Glasgow, the contract price being £3290 4s. 8d.

SUCCESSFUL artesian well boring has saved the ratepayers of Tunbridge Wells an expenditure of £70,000. The Corporation had to decide whether a reserve water supply should be obtained by the erection of works at Ashdown Forest, Sussex, eighteen miles away, at a cost of £100,000, or an artesian well bored at Pembury, three miles distant, at a cost of £30,000. The last-named project was ultimately decided upon. The wisdom of the choice was proved, when, at the close of a six-days' pumping test, four new wells at Pembury yielded on an average 1,000,000 gallons of water daily. The water is of excellent quality, and as far as can be ascertained the supply is inexhaustible.

A MEETING of the owners and ratepayers of the urban district of Biggleswade was recently held at the Town Hall "to take into consideration and determine upon the expediency of consenting to the said Council promoting in the present Session of Parliament a Bill to constitute a Joint Board consisting of representatives of the Biggleswade Urban and Rural District Councils, and to confer upon such Board all necessary and proper powers in regard to the execution of works for the supply of water to the urban district of Biggleswade and to the whole or parts of the rural district of Biggleswade, together with such further powers as may be incidental thereto, including the raising of the necessary funds, and that the expense of promoting such Bill (so far as the same shall be payable by the Urban District Council) be charged upon the District Fund and General District Rate." The resolution was carried unanimously.

THE St. Helens Water Committee has for a considerable time pursued a settled policy, having for its object the provision of a sufficient number of pumping stations and wells, which were felt to be the first necessity for properly supplying the borough with water. During all this time the Committee has been fully alive to the importance of securing additional reservoirs for the storage of water to ensure a continuous supply in the event of breakdowns of the pumping engines or mains. With the near approach of the completion of the Melling scheme, the Committee is in a position to consider the reservoir question. A special meeting was held in the water engineer's office recently, when the chairman (Councillor T. R. Dixon-Nuttall) laid the matter before the members, and after discussing the pros and cons, it was decided to take steps to construct a reservoir. Plans for a covered reservoir will be prepared. The probable cost is £30,000, but it is expected that this will not increase the water rate by more than one halfpenny.

A MEETING of ratepayers, convened by the Mayor, was held last week at Louth to consider a proposal made by the Highways Committee of the Corporation to purchase the Louth Waterworks Company either by arbitration or by the payment of a sum of £15,000. The Highways Committee, having decided in favour of the purchase, obtained the opinion of Mr. Mansergh, who, having examined the property, recommended that the Council should not offer more than £15,000. The Town Council then offered £13,900, which was declined. The Highways Committee then recommended the Council either to increase its offer to £15,000 or to submit the matter to arbitration, which, Mr. Mansergh estimated, would cost between £2000 and £2500. The company have made arrangements for obtaining a supply of water to supplement their present supply from Welton, and the Corporation, having discussed

the matter in committee, decided to take counsel's opinion upon the legality of such proceeding. The opinion received is against the company.

LIGHTING.

The Chester Gas Bill has passed the Committee of the House of Lords unopposed.

The Birstall District Council's Electric Lighting Order, granted by the Board of Trade, has been confirmed by the Examiners of Standing Orders in the House of Commons.

Mr. Malet, on behalf of the Local Government Board, held an inquiry at the Town Hall, Conway, into the application of the Corporation for power to borrow £800 for gasworks purposes.

Mr. W. J. Dibdin has reported to the Gravesend Town Council the result of a test which he had made of the quality of gas supplied to the local testing station: Illuminating power, 14·8 candles; pressure, 1·3in.; sulphuretted hydrogen, none.

At a recent meeting of the Pinner Parish Council the Clerk read the report of the Board of Trade with reference to the Provisional Order of the Pinner Gas Company, in which it was stated that the Order would be granted, subject to certain modifications.

The Town Surveyor having reported to the Malvern Urban District Council on a scheme for establishment of a refuse destructor in conjunction with an electric lighting installation, a public meeting of ratepayers carried a resolution in favour of the scheme by a considerable majority.

The British Columbia Electric Railway Company, Limited invite subscriptions for an issue of 6400 non-cumulative 5 per cent. preference shares of £10 each, ranking for additional dividend rateably with the ordinary shares after such ordinary shares have received 7 per cent., being the balance of the authorised issue of 20,000 shares.

Last week a Committee of the House of Commons began the consideration of the Mond Gas Bill. The Bill authorises the formation of a company, with a capital of £1,000,000, to supply gas manufactured under patents taken out by Dr. Ludwig Mond for power and heating purposes in the large industrial district 100 square miles in extent to the north-west of Birmingham.

At a recent meeting of the Aberdeen Electric Lighting Committee, the gas manager reported that for the month of March there had been manufactured 53,528,000 cubic feet of gas, as compared with 53,723,000 for the corresponding month last year. The sale of coke had realised during March £858, as against £844 in the corresponding month of 1900. Ammoniacal liquors realised £634, as compared with £892 in March of last year.

The Ardrossan Gas and Water Bill was considered before the Commission under Private Procedure at Ayr on the 24th ult. The Bill seeks power to extend the gas and water schemes already in the hands of the Corporation, at a cost of about £31,000. The only opponents were the Ardrossan Harbour Trustees, who objected to being brought within the rating areas, and whose opposition was confined solely to being included in the rating areas. After evidence for the promoters, led by Mr. A. S. D. Thomson, who appeared for the promoters, Mr. Constable, who appeared for the objectors, stated that he had no evidence to place before the Commissioners. The Commissioners, after some consideration, held that the preamble of the Bill would be held as proved if certain legal rights were conserved to the owners of the harbour of Ardrossan. It was accordingly agreed to frame a clause giving effect to this suggestion, and the preamble of the Bill was then passed.

In the House of Commons, on Friday, the Colwyn Bay and Colwyn Urban District Gas Bill was read a third time. The Arlesey Gas Bill and the London and India Docks (New Works) Bill were read a second time.

At Gloucester last week Mr. Henry Knowles conducted a sale of consolidated ordinary (New) stock (ranking for a maximum dividend of £5 per cent. per annum) in the Gloucester Gaslight Company, at the gas offices. There were 50 lots of £100 each for disposal, but only 21 were sold. The total realised for the 21 lots was £2526 10s.

The lighting of the Imperial Theatre, London, by electricity, both for the stage and front of the house, has been carried out by Messrs. Vaughan and Brown, Limited, who also supplied the gas braziers, fire hydrants, &c., fire-proof curtain, and ventilation. The large tableaux curtain was also fixed by the same firm. The whole of this work has been excellently carried out under the personal supervision of Mr. G. C. Vaughan, A.M.I.E.E.

At the ordinary weekly meeting of the Dublin Port and Docks Board a report was read from the Engineer in reference to a letter calling attention to the advantages of the "intensified gas system." Mr. Griffiths, in the course of his report, stated that the "intensified gas system" simply meant that the gas was compressed mechanically before being burned. Through Mr. Wigham's courtesy he had had an opportunity of inspecting his apparatus at Capel-street. There was no doubt as to the advantages of the system from an illuminating point of view, as anyone who had seen it at work in the Strand, London, could testify.

Much interest locally is being taken in the application of the Elland Gas Company for further powers. The District Council decided to oppose the Bill in Parliament unless certain substantial concessions, including option of purchase, were granted. Negotiations which have been proceeding between the Council and the Gas Company have up to the present failed to produce any satisfactory agreement, and the Council has now decided that an offer of £125,000 be made to the company for the undertaking and all the assets, the company to pay their own debts and liabilities. If this offer is not accepted the Council will persist in its opposition to the Bill.

The new gasworks at Perth were formally inaugurated on Saturday last. The works are beautifully situated on the banks of the river Tay, and with siding accommodation from the adjacent railway every facility is provided for the rapid and ready working of the gas establishment. The conditions of working are greatly improved, and every facility for cleanliness is provided, and the new gasworks as completed are amongst the finest and best-equipped in Scotland. The new works occupy an area of about 4¼ acres. The site is quite away from the city and from the direction of its present extension, and yet near enough for convenience in working. The gasholders which supply the lighting district are midway between the new works and the city. The initial capacity of the works is equal to a make of one million cubic feet of gas per twenty-four hours, and the works are capable of being extended within the boundary walls to at least three times that quantity, while the arrangement is such that these additions can be carried out without change of existing plant. The works have been designed with great care as to their being equipped with the most modern appliances, and as to the possibility of extension as consumption demands without disturbance of existing plant. The offices consist of a handsome suite of rooms—the general office, manager's room, assistant's room, drawing-office, and lavatory. The meter and exhauster houses are tastefully finished with tiled floor and dado. The workmen's rooms attached to the retort-house are well furnished and fitted with baths and lavatories of the best class. The roof of this building is formed by an

iron water tank for water pumped from the river, which supplies the whole works, except for drinking and washing purposes. A large fitting shop, with smithy attached, enables all necessary repairs to be effected on the spot. A weighbridge and office is erected on the railway siding at the junction of the high and low-level railways, so that all materials received and despatched may be weighed and recorded. The works are most complete in every detail.

GENERAL.

The Ludlow Town Council proposes to borrow £7500 for an electric lighting and refuse destructor scheme.

A loan of £9445 has been sanctioned by the Local Government Board for the extension of the Ilford Urban Council's Isolation Hospital.

A Local Government Board inquiry has been held at Hastings with reference to the application of the Town Council to borrow certain sums of money for wood paving, &c.

Last week, after an exciting debate, the Norwich Town Council decided to appoint a lady Sanitary Inspector to visit the homes of the poor and give advice on health matters.

The Baths Committee of the Manchester Corporation has approved of the plans for the baths which are to be built in High-street, Chorlton-on-Medlock, at a total estimated cost of £40,000.

A Local Government Board inquiry was conducted at Gosport recently into an application by the District Council for permission to borrow £3840 for the erection of a number of houses for the working classes of the district.

Mr. M. K. North, one of the Local Government Board's Inspectors, conducted an inquiry at Blackpool into the Corporation's application for sanction to borrow the sum of £3085 for the purposes of private street improvements.

Mr. H. H. Law held an inquiry at the Town Hall, Morley, recently, on behalf of the Local Government Board with respect to an application by the Corporation for sanction to the borrowing of £21,500 for works of street improvement, £18,700 for waterworks purposes, £7035 for purposes of electric lighting, and £3600 for the erection of stables and the purchase of horses, carts, &c.

A Local Government Board Inspector has held an inquiry at Rugby with reference to the Council's application for sanction to borrow £2500 for the completion of the public offices, £820 for the purchase of land for widening West-street, and a further sum of £2500 in order to carry out certain requirements of the Local Government Board in the provision of a new storage reservoir at the river Avon.

The question of erecting a destructor has been again considered by the Moss Side Urban District Council. Mr. Lees, the recently-returned member for east ward, on behalf of his constituents, said he had a mandate to oppose by every possible means the erection of a refuse destructor, but after discussion the recommendation of the Scavenging and Health Committee to consider a tender for carrying out the scheme was approved.

We learn that an effort is about to be made to establish a municipal system of public telephone communication in Liverpool. Encouraged by the success which has attended the experiment in Glasgow, many public men in Liverpool believe that the time has arrived when the city should have an independent telephone service, under the control of the municipality, and thus put an end to the monopoly which has been so long enjoyed by the National Company. The matter will be brought before the next meeting of the City Council, and that body will be asked by resolution to declare in favour of the establishment of a municipal system.

Motor fire engines for use in London are now under consideration. Commander Wells has recommended as a trial car, one manufactured by the Locomobile Company of America, and the Committee have advised the London County Council to purchase such a car for £286.

In Lambeth the Local Committee which has in hand the securing for the public use in perpetuity of forty-three acres of wooded land as an addition to Brockwell Park, has now received nearly the whole of the amount required for the purchase—namely, £66,858. A recent grant of £200 from the Peabody Donation Fund, and a second grant of £500 from the Southwark Corporation, bring the Committee within £500 of the total amount required. More small subscriptions from tenants and landlords in the locality would, it is stated, be appreciated; and it is noted that not a single small subscription has been sent in from the appeal exhibited on a huge board at the Herne-hill gate of the park for some months past.

At the meeting of the Limerick Corporation last week, the Mayor presiding, a lengthy report was read from Sir Acheson MacCullagh, Local Government Medical Inspector, relative to the sanitary condition of Limerick. Sir Acheson MacCullagh states that the streets are kept in a very dirty condition. The scavenging staff appear quite unable to cope with the work. The dirty and insanitary condition of the smaller streets, lanes, and passages was most noticeable, the surface of the roadways being most uneven and littered with ashes, vegetable refuse, and other objectionable matter. Pigs were kept throughout the city in most unsuitable yards and premises. There were a good many houses in the city unfit for human habitation, and he was informed that though magistrates' orders to close these houses had been obtained, the orders had not been enforced. A large majority of the houses in lanes, &c., off the main streets were entirely without sanitary arrangements, and many were overcrowded. The Mayor said the citizens were very heavily taxed at present, and if the suggestions made were carried out it would mean 15s. in the pound on the rates.

Under the guidance of Dr. Watt, Medical Officer for the county of Aberdeen, an inspection of the Gordon Hospital, Ellon, was made recently by the members of the Ellon District Committee. The original hospital was founded some twelve years ago, but quite recently extensions have been effected, consisting of a new block of buildings and a new flat added to the administrative block. The total cost of the original structure was £747, and it is expected that with the recent extensions the capital expenditure will approach £2500. The first visit was paid to the diphtheria department, which is situated in the left wing of the new block, and being self-contained, lies furthest away from the road. The right wing of this building is for typhoid cases, and in each wing there is a nurses' room, used also as a reception room for doubtful cases. The accommodation in this block is for fourteen adults, besides several small cribs for children. The administrative block lies some few yards nearer the road. After inspecting these two blocks, the members of Committee examined the original block, which is now reserved for scarlet fever cases. The accommodation is the same as in the new block, but improved lavatory arrangements have recently been provided. The steam disinfector, mortuary, drying loft, &c., lie in an outhouse to the left of the main buildings. Much interest was taken in the working of the disinfector, the process of which was described by Dr. Watt. The germ-laden clothing, bedding, &c., is put into a wire cage at one end of the machine and thoroughly steamed, after which hot currents of air are introduced to facilitate the drying process. As explained by Dr. Watt, no matter how great the vitality of the germ spores, half an hour in the disinfector would destroy all life.

The work of the Health Department of Birmingham is increasing so rapidly that the establishment in Rotton Park-street, where the dry refuse collected on that side of the city is burned, is no longer adequate to the demands made upon it. Fortunately, the Committee are in possession of a piece of land adjoining the present premises, and they are desirous of utilising this for the erection of a new destructor, together with a range of stabling and the necessary chimney-stack and buildings required in connection with the work carried on by the department. At a meeting of the Health Committee, last week, plans of the buildings were under consideration, but they were not finally approved, inasmuch as a few alterations were suggested. These will be made, and at the next meeting the subject will once more be reviewed, when the scheme will probably be accepted and recommended to the City Council for adoption. The total cost of the extensions and equipment is estimated at about £30,000. The new destructor will be built on the lines of the Montgomery-street establishment.

PERSONAL.

The salary of Mr. W. H. Wells, Sanitary Inspector for Bilston, has been increased to £120 per annum.

The salary of Mr. J. A. Brodie as City Engineer for Liverpool has been increased from £1000 to £1200.

The salary of Mr. A. B. Holmes, Electrical Engineer for Liverpool, has been increased from £1600 to £1800.

Dr. W. E. Robinson has been appointed Medical Officer and Public Vaccinator for the Sonning district of Wokingham.

The City Coroner, Mr. S. F. Langham, will retire on June 25th on a pension of £600 a year, the salary of his office being £1000.

The Local Government Board has sanctioned the re-appointment of Dr. J. Dixon Adams as Medical Officer of Health for the rural district of Yeovil.

Dr. William Collingridge, M.A., M.D., LL.M., has been appointed Medical Officer of Health for the city of London at a salary of £1000 per annum.

Mr. Frank L. Teed, Public Analyst for Islington and Camberwell, has been appointed Public Analyst for the city of London in room of Dr. Sedgwick Saunders, deceased.

Miss G. D. Bevan has been appointed an additional Sanitary Inspector for the Borough of Camberwell. The salary is £125 per annum, rising by yearly increments of £5 to a maximum of £150.

LAW CASES.

Liabilities of a Drainage Board.

In the Irish King's Bench Division No. 1, before the Lord Chief Justice and Mr. Justice Boyd, judgment was given in the case of the King (Parker) *v.* Carrigrohane and Ballincollig Drainage Board, in which the question for decision was whether the Drainage Board could be compelled to pay the respondent, who was prosecutrix, the sum of £189, which included £9 for damages awarded in an action brought by her against the Board for injury caused to her property through the negligence of the defendants in the construction of the works authorised by the Drainage Acts, and £139 for costs of action, and £40 being taxed costs of an unsuccessful appeal by the Board against the judgment in the action. It was contended by the Drainage Board that they had no money in hand, and no power to levy a rate to pay the demand.

Mr. Justice Boyd, in delivering the judgment of the Court, said he was of opinion that the Drainage Board had power to levy a rate for payment of the claim, and should be compelled by mandamus to do so. It seemed absurd that the Legislature should have conferred privileges on the Board without imposing on them corresponding obligations.

The Lord Chief Justice considered it would be very unreasonable to hold that this Board could sue a person and recover from him, and that if they were beaten, costs could not be recovered against them. It was decided in the Court of Appeal that the action lay against them, and it appeared to him to be a necessary corollary to that decision that costs should be enforced. Mr. Justice Barton agreed with the result Mr. Justice Boyd and he arrived at. They would give judgment for the amount claimed and costs for the respondent.

Counsel for the prosecutrix—Messrs. M. J. Bourke, K.C., and Geo. Green (instructed by Mr. Geo. Murphy). For the defendant—Mr. A. M. Sullivan (instructed by Mr. M. Healy).

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2179.—Insufficient Drainage: Proceedings.—"A. S. I." writes:—"There are three houses in the district where I found the sink drainage was not disconnected, but was connected directly to a soak-away cesspool. Some of the drain pipes were broken, and generally the joints were improperly made. The cesspool had an overflow into a ditch. A statutory notice was served to take up existing drains, provide traps, filters, and

THEIR CHARACTERISTICS AND ANALYSES, WITH AN ACCOUNT OF

ARTIFICIAL STONE & ASPHALT

By W. J. DIBDIN, F.I.C., F.C.S., F.S.I., &c. &c.,

Formerly Chemist and Superintending Gas Examiner to the Metropolitan Board of Works and London County Council.

PRESS OPINIONS.

"A very useful little treatise. . . . It deals with the character and chemical composition of the various materials used in making mortars and cements, and the methods and results of their chemical analysis. . . . We recommend this book not only as an excellent text-book for students, but also as a practical treatise for practical men."—*British Architect.*

"There has certainly been need for a book dealing with calcareous structural materials from the builder's and architect's point of view. Questions of the quality of lime and of cement, of the composition of mortar, of the suitability of diluents, such as sand and gravel, come frequently before the members of this trade and profession, who have to pronounce upon to the best of their ability. The author has succeeded in putting together a number of useful statements—especially to be commended is his dissertation on mortar. The section on asphalt, embodying Mr. Clifford Richardson's researches, will be acceptable."—*The Engineer.*

intercepting traps, and cut off any flow from cesspool to ditch. On revisiting the premises I found that the drainage had not been carried out as required by the notice, and that some sinks were blocked up entirely. Will you kindly advise whether the requirements given by notice under Sec. 94 of the Act of 1875 are in order, and whether you would advise proceedings being taken under Sec. 95, as the requirements have not been carried out, but some work done which is quite different to that prescribed, and the drain has been disused."

Answer.—The requirements given in the notice under Sec. 94 were proper and necessary, and they would, in our opinion, be supported by Justices. The Authority may now, on default of compliance with the notice, proceed under Sec. 95 for a summons against the owner. They may in the alternative serve a notice upon the owner under Sec. 23 of the Act of 1875—the houses being without drains sufficient for effectual drainage, and sufficiency in this case includes improper and unsatisfactory—to provide proper drains, and on his default they may carry out the work and charge him with the cost thereof. The advantage of proceeding under the section is that it is not necessary for the Local Authority to prove that a nuisance exists.

2181.—Insufficient Drainage: The Powers of Local Authority.—"Reval" writes:—"In my district, which is rural, I have received complaints of nuisances arising from the drainage of waste from house sink into an open brick channelling. The joints of some are very open and uneven, and allow waste water to stand and stagnate and cause bad smells. Can the Local Authority compel the owner to lay a covered pipe drain properly trapped, &c.? The house in question is a farm house."

Answer.—The house is without a drain sufficient for effectual drainage, and the Local Authority are enabled under Sec. 23 of the Act of 1875 to require the owner to make a covered drain emptying into a covered cesspool or other place which they may direct, the drain to be of such materials and size as on the report of their Surveyor may be necessary. On the owner's default the Local Authority may do the work and recover the cost from him. The waste pipes must be properly disconnected from the drain and discharge over trapped gullies.

2182.—Water Supply: Closing Well: Cost of Providing New Supply.—"Inspector" writes:—"B is the owner of a house. The water used for domestic purposes is found on analysis to be bad. As it would be impossible to provide a new supply for £8 13s. 4d., what course could my Council take in such a case? Is there nothing we can do but close the well?"

Answer.—The Rural Sanitary Authority should proceed under Sec. 70 of the Act of 1875, and obtain power to close the polluted well. They should also serve notice upon the owner under Sec. 3 of the Public Health (Water) Act, 1878, to provide a sufficient supply for the use of the inmates of the houses. If the supply cannot be obtained for £8 13s. 4d., the Rural Authority may apply to the Local Government Board to determine what is a reasonable sum, not exceeding £13 in any case. The owner may object to the notice on any of the grounds mentioned in Sec. 4, and the Sanitary Authority may be required to contribute a part of the expense of providing the supply.

2183.—Testing House Drains by Private Request not Inspector's Duty.—"Inspector" writes:—"Am I as Inspector obliged to go and examine and test the drains of dwelling-houses at the request of the owners or occupiers free of cost simply to satisfy their curiosity? For instance, a mansion is let to a person who, before closing the agreement, wishes to have the drains tested. The Inspector is sent for, and spends the greater part of two days in the work of examining and reporting. Query. Can the Inspector charge for the work, and if so, at what rate?"

Answer.—It is not the Inspector's duty to perform such work at the request of private owners. He is employed by the Sanitary Authority, and not by the former, and when he executes work which should be carried out by a private tradesman, which is distinctly the work of such in the case named, his position is being abused, and he is wrongfully employed. If the Inspector is employed to give the whole of his time to the duties of his office he must not charge any fees without the consent and direction of the Sanitary Authority. The fee may be from 10s. 6d. for a small house to £2 2s. for a mansion.

2184.—Sanitation: Lectures on.—T. G. B. writes:—"Referring to query 2170, April 18th, 'Memo,' who asked for matter for a lecture on 'Sanitation,' would find a lecture entitled 'Breathing and Ventilation,' which is freely illustrated by Mr. (now Dr.) Wm. Daley, Chief Sanitary Inspector of Bootle, crowded with useful information. The lecture was dslivered to the members of the North-Western Association of Sanitary Inspectors, and published at 1s."

Answer.—We are indebted to our correspondent for the information. Copies of this and any other books may be obtained post free at the published price from the office of this Journal, 5, Fetter-lane, London, E.C.

2185.—Death-rate in Thirty-two Great Provincial Towns: Where Obtainable.—"M. O. H." writes:—"Would you kindly give me the birth-rate, death-rate, and zymotic death-rate for the year 1900 in the thirty-two great provincial towns. If you have not these at hand, will you kindly inform me as to where I coold obtain them?"

Answer.—We regret we are unable to give the statistics desired. These, however, we believe, will be furnished the querist on application to the Registrar-General, Somerset House, London, W.C.

NUISANCES AND METHODS OF INSPECTION.[1]

By J. Spottiswoode Cameron, M.B., B.Sc., M.O.H. Leeds.

NUISANCES AND INSANITARY CONDITIONS.

(*Continued from page* 382.)

What these are we shall now proceed to consider, and I shall ask you to imagine that you are going with me over an ordinary dwelling-house. On the slips which I hold in my hand are a series of questions to which I ask the District Inspectors in Leeds to supply me with answers, when they are going through their districts from house to house. The queries are grouped and are printed on ruled paper. They are intended to be pasted into little note-books with lines the same distance apart, and are so arranged that the Inspector can have the queries open while he is writing his answers to them in the book. The answers only are written. The numbers in the column on the left correspond to the columns in the house-to-house book into which the information has to be afterwards transferred. In this latter there is room for ten houses on a folio, and the end of the book has some cross-ruled paper for diagrams and plans. The Inspector is advised to familiarise himself with the questions and to write the answers in his note-book before leaving the house. The questions are not, however, arranged in the order in which the examination would always be most conveniently made.

Cols. House-to-House Queries.

1. Date of previous inspection :
2 and 3. Street | Position in street and aspect :
4. Occupier :
5. Owner's name and address :
6, 7, and 8. Trade in house | No. of rooms | Kind of rooms, cleanliness of | Area of ground floor :
9 and 10. No. of inmates : $\frac{\text{M—5 | 5-15 | 15 +}}{\text{F —5 | 5-15 | 15 +}}$
11. Water supply : From which Corporation tank ?
12. No. rooms in which windows open : Both sashes, one sash, casement.
13. Rooms with chimney | Ditto with chimney open :
14 and 15. Is house back-to-back ? | Is there a through draught ?
18 and 19. W.C. (special queries) | Sink :
20 and 21. Basement drains | Other drains (bath, lavatory, &c.):
22, 23, and 24. Main sewer | Depth, feet | Size, inches | Distance, yards | State if pipe, brick, stone ; shape :
25, 26, and 27. Yard drains | Fall pipes | Eaves spouting | Distance of street gullies, in yards :
28 and 29. Damp walls and cause | Foul smells :
30 and 31. Privy—kind | Condition | Distance, yards | No. of families using it : Ashpit, same details :
32. Result of drain test | Remarks : Distance of street gullies, whether with catchpit or not, &c. Other nuisances.
33. References :

There is another slightly different form for use in cases o zymotic disease. The principal difference lies in the greater detail required as to the work, age, and movements not only of the patient himself, but of the other members of the family. In the corresponding zymotic register there is a space under the column for work or school place, for particulars as to flushing and ashpit cleansing of the said work-place or school.

A few convenient contractions will be found on the back of the zymotic question form.

CONTRACTIONS.

D. means drain of house (as sink pipe, cellar drain, &c.), connected *directly* to street drain or sewer.

T. means that an S or syphon *trap* is interposed.

C. means that the house drain is *cut off*, and opens over a trapped gulley or grid outside the house.

T.C. same with syphon trap inside.

T.V. means that the trap is efficiently *ventilated*.

S. means that the fall pipes or *down-spouts* go directly into the drains.

S.C. that the spouts are disconnected from the drains.

F.V. means that the W.C. soil-pipe goes *full* size above the eaves.

V. 1½ means that a ventilating pipe of 1½in. diameter goes from the trap of soil-pipe above the eaves, and similarly for other sizes.

Memo. Addresses to which members of family may have been sent must be given in full. Extent and efficiency of isolation to be stated. Any conditions dangerous to health not coming under headings to be recorded.

Let us now go in imagination over the house. We shall begin by going downstairs.

In descending the cellar steps, notice would, of course, be taken of the amount of air and light in the passage, and of any smell of coal gas. The flooring of the basement should be carefully examined for signs of damp, should be tapped occasionally for hollowness, and carefully inspected for marks of recent disturbance, and for any ring marks or other evidences of mobility. The illustration (Fig. 1) shows what we once found in Huddersfield in examining a house in this manner. The drainage of a group of houses had been carried to the back, and the sink and bath wastes all carefully disconnected. After all this was done, however, the Corporation brought a new sewer along the front street, and issued orders that all drains should be connected to it. The owner must either reorganise his drainage, or collect it, and bring it under one of the houses. He elected to do the latter, and, having a horror of sewer gas, determined to protect his tenants by an intercepting trap. This he placed in the middle of the keeping cellar floor, and thoughtfully placed a flag over it, by which its whereabouts could be easily ascertained. On removing

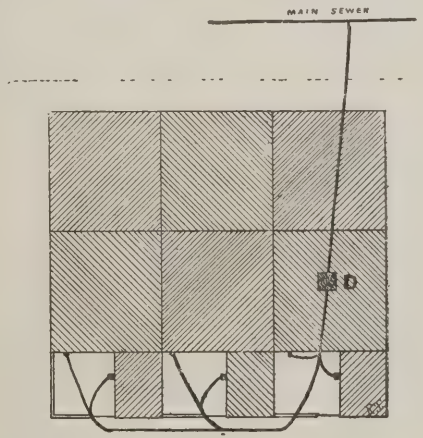

Fig. 1.

[1] A lecture delivered in the Philosophical Hall Leeds, April 13th, 1901. The illustrations to this lecture are from Dr. J. Spottiswoode Cameron's little work, entitled "Is my House Healthy?" published by Mr. R. Jackson, Leeds, and are reproduced in these columns by special permission

the flag, this is what we found, (Fig. 2). Fortunately the days of mason's traps are numbered, but a trap of any kind in this situation would be sufficiently objectionable.

Coal gas is often mistaken for a smell from the sewer. It is not only a nuisance on account of the discomfort it occasions directly, but, more especially now that water gas is being largely added to it at the works, it is a serious source of danger to health. Frequently the nose is a sufficient guide to the leak. Sometimes it is necessary to light the gas jets all over the house, to then turn all the burners off, and last of all the meter, and having

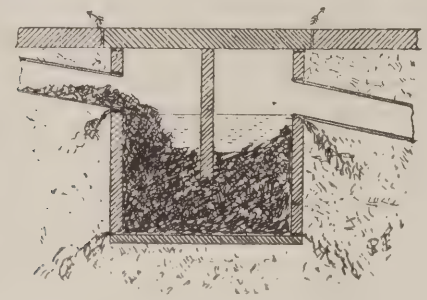

Fig. 2.

done so, to leave the gas pipes thus filled till next day, in order to ascertain by the presence of air in the pipes if there has been any leakage.

The ventilation of the basement is frequently defective. There should be some provision as by a Sherringham ventilator (Fig. 3) for the admission of fresh air from the outside of the house. Too often an attempt at this is made by letting the air in at the cellar window, which is frequently just over the trap in the area that is kept foul by the dish water from the kitchen sink.

It is with some a question of how far dampness of the keeping cellar is a fault and how far it may be regarded as a virtue. There can be no doubt whatever that if the damp is due to sewage impregnation of the subsoil, still more so if it be attributable to leaky drains, that it is an evil to be dealt with. Should the damp be due to a boggy condition of the ground on which

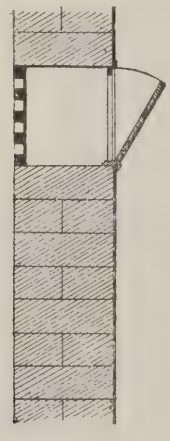

Fig. 3

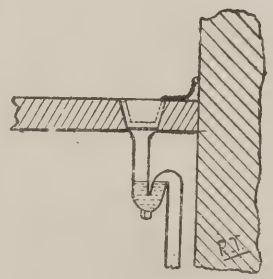

Fig. 4

the house is built, although the moisture be merely the soakage from vegetable matters, if the amount of moisture entering be at all excessive, it calls, in my opinion, for remedy. On the other hand, if the amount of moisture be very slight indeed, and that little from the natural moisture of a clean soil, it may be disregarded. It is different altogether if the damp room is a dwelling room. Measures should in that case be taken to remove the dampness, or the use of the room should be discontinued. It is unnecessary to insist that in curing damp walls it is essential to ascertain the cause. Usually this will have to be postponed to a later stage of the examination.

It may seem a trifling point, but it is important to feel sure in making your survey of the basement that you have covered every portion of the excavated area. No coal cellar, chip-place, wine cellar, must be omitted, and you must have a clear idea when you have finished of the exact amount of the area left solid, and of the means taken to prevent dry rot.

The ground floor is most conveniently examined next. Here, again, an accurate notion of the plan of the house must be obtained, and every inch of floor space explored. Special note must be taken of boarded-in pipe courses and the way they run. Any

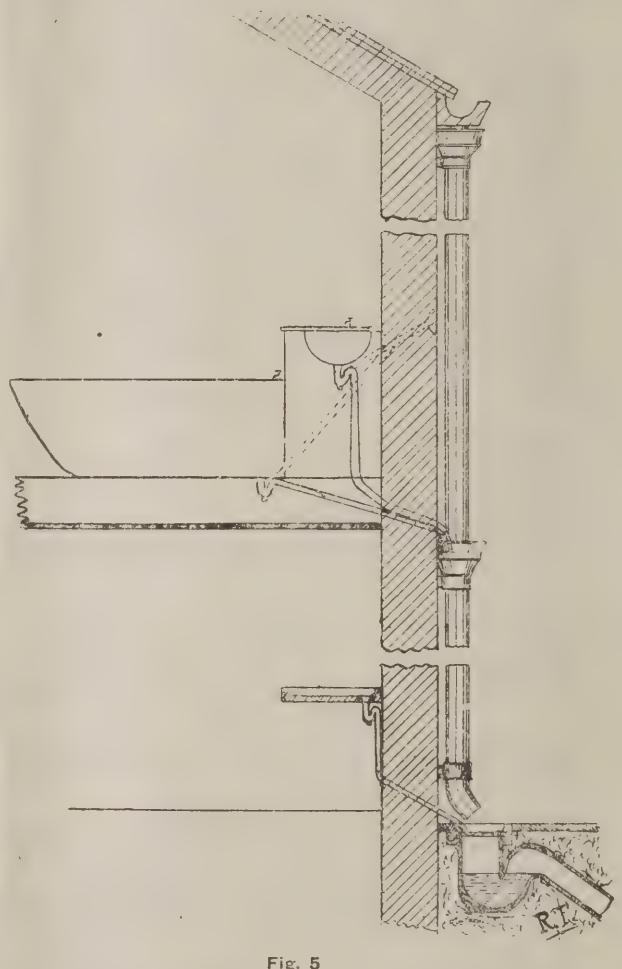

Fig. 5

guess as to what is behind must be afterwards verified at the appropriate time and place. Loose paper, scarred ceilings, will be inquired into. In working over any area, either on the ground floor or in the basement, it is convenient to have some fixed practice as to procedure. Start, for instance, at the foot or head of the cellar stairs, as the case may be, and keeping persistently to the left, leave no opening unexplored and no void space unaccounted for. In this way you may cover the whole ground with some amount of certainty. Important, however, and essential as it is that your inspection should leave no portion of the dwelling unexamined, certain parts will claim special attention. The kitchen and its sink, and the scullery and its wastes are amongst these. The sink, whether in the kitchen, in the scullery, or in the basement, must have its waste taken by the shortest possible route outside

the house and severed in the open air. Inside the house it is on the whole convenient that there should be an S trap to prevent a back current from the gully trap outside. It should be small, because every trap is a nuisance, and the larger the trap the greater the nuisance. The slide shows the usual trap with which you are all familiar (Fig. 4). The usual mode of disconnection is shown in another diagram (Fig. 5). Unfortunately, there still exists in many

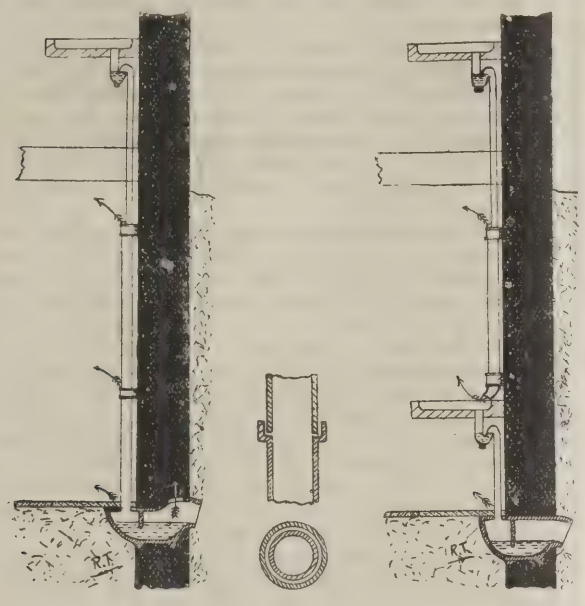

Fig. 6 Fig. 8 Fig. 7

houses, even in Leeds, other and less unwholesome methods of dealing with the sink waste. Two of these by means of "box traps" are shown in the diagrams (Figs. 6 and 7). Not infrequently the evil is aggravated by the employment of pipes of different metals to remove the wastes. But even if the metal used be the same throughout, there will sooner or later be a giving way of the luting of the joints and an escape of the gaseous products of decomposition, as the points shown by the small arrows in the diagrams. That this must be so is evident if we consider that the upper and inner pipe (Fig. 8) must be heated by the passage of hot water down it, and consequently expand before the lower and outer portion of the joint gets at all warm. The intermediate luting is therefore compressed. Exactly the contrary occurs when on a warm day cold water goes down the pipe. Then the inner and upper tube contracts, pulls upon the luting, and these alternate processes in time destroy the joint. As just said, the destruction is all the more rapid if the inner and outer metals have themselves different coefficients of expansion. It is hardly necessary to say that an inspection of the sink drains will include an examination of them in action as well as a careful inspection of the pipe by the eye. The inside trap will be examined and, perhaps, cleaned. The outside gully may, if near, be examined now, or, if difficult to get at, later on when taking the outside of the house.

(*To be continued.*)

In a long report, presented by the Local Government Committee to the London County Council on Tuesday, it was pointed out that in the City there are a large number of hereditaments considerably under-assessed, the total estimated deficiency being at least £690,000.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

THE NEED OF UNIVERSAL EDUCATION ON SANITARY MATTERS.

(*Continued from page* 390.)

Cleanliness of person and surroundings.—This is a branch of sanitary education that is undoubtedly of the first importance, but which receives perhaps the least attention. The regular and thorough cleansing of the skin is absolutely necessary to those who would enjoy perfect health. How people exist without a free use of the bath seems difficult to realise when one considers that the perspiration from the skin is, in its way, as impure as the contents of the slop pail or sink waste, and when this is allowed to remain on the surface of the body it becomes a kind of varnish over the pores of the skin, which effectually clogs part of the drainage system of the body, with serious consequences. The ancient Romans knew this, and were far ahead of even the opening of the twentieth century in their cleanly habits of washing and bathing.

I hope the time is not far distant when regulations will make it compulsory to include a bath in every house, for a daily bath and the regular change of clean clothing are invaluable for everyone, and especially for children. I know, however, that the education of the poorer classes in this important matter has not yet had the desired results, for I have seen baths used in houses for dog kennels and rabbit huts, doing duty also as washing tubs, or full of plants, instead of for bathing, the purpose for which they were provided. Here is a case of giving people a benefit without first educating them as to its proper and necessary use.

Then the question of clothing, looked at from a sanitary point of view, is a most important one. For instance, colour has an effect upon health, and the habit of wearing dark clothing in summer in this country should be discouraged.

Surely one can mourn the loss of one's friends without putting on deep black clothes, for black in summer absorbs the heat to a greater extent than any other colour, nor is it warmest in winter, for it gives off heat more readily than lighter shades. Its only point is that it will store up a large amount of dirt and dust without showing it, and consequently we don't grieve about the dirt, and like to assume it is not there.

Then we have the dreadful habit recently adopted by ladies of letting the trains of their skirts act as pavement sweepers. Looked at from a sanitary point of view, and without any reference to fashion or custom, it is difficult to imagine a more dirty or offensive habit than the trailing of their skirts in the nameless abominations of the streets. How any decent-minded woman tolerates and obeys such a fashion is altogether beyond man's comprehension; surely there is need of further education here. If mothers really knew what risks they place themselves and their children in, I do not think such a state of things could exist. How many colds and fevers are brought on by inefficient clothing. The wealthy adopt a somewhat scanty apparel in ball-rooms and theatres where draughts abound, and at times a very doubtful atmosphere also, for fashion's sake, whilst our poorer people lay themselves open to similar dangers through poverty, often through no fault of their own.

Men also become the slaves of fashion, and during summer, in dry weather, turn the bottom of their trousers up, and make dust and dirt collectors of them. This is as hygienically ridiculous as it looks absurd. The most important item with respect to dress is that it should be kept as clean as possible, especially under-clothing, which is absolutely necessary to that perfect

health which science and common sense might ensure. As sanitary experts, therefore, our duty dictates that we should advocate ample provision for washing purposes, especially in the homes of our artisan classes, whose heavy manual work makes a frequent change of underclothing advisable. A good bath and change of clothing are often as valuable and refreshing as a few hours' sleep.

Infection.—I now come to another important point, which want of time makes it necessary to touch upon very briefly, namely, "The spread of infectious fevers." The carelessness with which many people expose themselves and those about them, to this risk is astounding, and must be largely due to ignorance, especially when we find people trying to hide infectious cases from the Sanitary Authorities, to escape the trouble of disinfection and its consequent inconvenience in their homes—an inconvenience which cannot be compared with the probable danger to themselves, their friends, and the whole district. That our poorer classes willingly assist one another in times of sickness and trouble is a characteristic we must all admire; indeed, one wonders what would happen to a household with slender means if this noble, charitable feeling did not exist. At the same time, it is one of the chief causes of the spread of diseases. Frequently before the nature of the sickness is known many kind and sympathetic neighbours are around the patient, and take away and spread infection before the officials have any chance of isolation, and these afterwards have the greatest difficulty in tracing where contact begins and ends. Proper knowledge would suggest the greatest caution, and assist materially in preventing the spread of fevers in such a manner. Then we have the carelessness of those who themselves suffer from infectious troubles; take the case of consumption as an example. It is a common occurrence for people so suffering to spit about in public, down gratings, over hot-water pipes, in railway carriages, and other equally objectionable places. This is a habit which is dangerous to others, for the germs of consumption become dry, mix with the dust, and are blown about, spreading infection all round.

In their own interests, also, consumptives should be careful to select residences with dry, well-drained subsoils, with concrete below the floors, and to have the fullest ventilation possible. Rats spread fever through the sewers, and should be treated with suspicion wherever found; they can lay on sewer gas to a house by their tracks as effectually as can an open pipe. Water traps are provided to the drains as a security against sewer gas, but the average householder, who knows more about mouse-traps, does not consider that during dry weather the water evaporates, if not supplied by some fitting in regular use, making the trap worse than useless, though he would willingly protect himself by filling it with water, did he know the necessity. People would not drink dirty water if they could get it clear by going to a tap, neither would they breathe dirty air if, by filling the water seals, they could avoid it. Flies are doubtful inhabitants, and their ability to spread disease is a question open to discussion. They do not like cleanliness, and generally do not visit a house run on sound sanitary principles.

The question of cremation, as against our present system of burial, is one that the nation must give careful consideration to in the immediate future. I am aware that sentiment enters largely into this question, and will make it most difficult to tackle. Cremation was largely practised by the ancient Greeks and Romans, and there is undoubtedly a feeling amongst the educated classes for its reintroduction under proper safeguards against abuse. In dealing with infectious bodies, both in the house, the church, and the ground, it must be admitted that there is the greatest risk, especially in town cemeteries in thickly populated districts, where both air and water are liable to contamination, whilst the traditional Irish custom of "waking the dead", is positively dangerous. Cremation promptly carried out effectually removes these risks, and should have the earnest consideration of this Institute. Indeed, these are subjects far-reaching and important, upon which there is great need of universal sanitary knowledge.

Good food.—The question of food is also a very important one, but I fear I am wearying you with illustrations to which any of you can add from your own experience. It is, moreover, more a question for the medical man than for the Sanitary Engineer; but the question of providing cool, well-ventilated pantries away from all chance of poisonous gases requires the careful consideration of the architect and the householder. I must pass on to the more difficult question of how the people are to be educated to so realise their individual responsibilities to the community at large that they will act every day so as to assist in the stamping out of preventable disease.

The following methods are worthy of consideration: First, sanitation and hygiene must take a very much more prominent place in the subjects taught in our schools; indeed, as I stated before, it is every whit as important as reading, writing, and arithmetic, if not more so, and the teachers should be carefully selected and impressed with its importance, and grants paid only on those students whose passes include this subject. This would lay a foundation for future improvement on a universal scale. Secondly, some effort should be made to reach the householder, for it is a question that comes home to all. This is much more difficult, but I believe might be done through those Authorities who have charge of the health of the people.

The time has arrived for the creation of a separate department of health—a "Government Board of Health"—upon which the medical and sanitary professions should be well represented, and which should be presided over by a Minister of Health. This would ensure a uniform practice on sanitary matters throughout the nation.

Local committees might be thoroughly reorganised and placed directly under the control of this Government Board of Health. This would remove them from the fear of local influences, which, at times, no doubt unintentionally, seriously hampers such Authorities in conscientiously carrying out their duties. Such a Committee might consist of the Medical Officer of Health, Borough Surveyor, the Engineer to the Water and Gasworks, Chief Sanitary Inspector, Chairman of Sanitary Committee of the Council, &c.

Free and popular lectures for the people on "Domestic Sanitation," and "The Natural Laws of Health" might be given in a simple and interesting form, especially to the artisan classes, whose limited means and residences in thickly populated districts make it so desirable for them to have a broad knowledge of such matters. I am deeply interested in this question of education, which must be considered in conjunction with that enormous problem, "The Housing of the Working Classes," if success in the latter is to be obtained. Although I fear I have not handled this subject in the efficient manner it deserves, I trust it will secure the careful consideration of the members of this Institute, and be dealt with more fully by those whose experience and ability best qualify them to move in the matter.

The Chairman, Mr. E. R. Palmer, having briefly spoken of the pleasure of seeing and hearing Mr. Bland, who had come such a long distance to give his paper, a cordial vote of thanks was awarded the author on the proposal of Mr. J. Farley, seconded by Mr. H. M. Dove, and supported by Messrs. T. M. Taylor and E. Durant Cecil, the last of whom referred to the good work already done voluntarily and gratuitously by the National Health Society.

BUILDING TRADES EXHIBITION.

[Third Notice.]

A lattice-girder roof covered with "Red Hand" felt formed the stand of Messrs. D. Anderson and Son, of London and Belfast. Within were samples of tarred felts, and inodorous felt for roofing and lining. On a raised bench were a small model of the circular wooden lattice girder felted roof; and by its side another model showing the various applications of silicate cotton or slag wool for sound and fireproofing buildings and insulating cold stores. Specimens were shown of silicate pipe cloth for covering steam pipes; hair fabric for covering hot and cold-water pipes, and brine and ammonia pipes; dry-hair felt in sheets and lengths; and plasterers' hair. The arrangements left nothing to be desired.

Golden anchor suspended from a beam was an attraction to any one who desired to inspect the "salt" glaze ware of Mr. James Woodward of Swadlincote. And here were arranged in excellent order the sanitary specialities for which his woodwork is well-known. Drain pipes with Esmy's patent excentric shoulder, and connections, manhole chamber, and fittings in white glazed ware, and garden edgings, interspersed with terra-cotta flower vases, chimney-pots, and bricks in a variety of colours made a very effective display.

Uralite is a fireproof and non-conductive material composed of asbestos fibre and mineral substances, and is a powerful non-conductor of heat, cold, and electricity. It is waterproof and unaffected by hot or cold water, atmospheric influences, and gases. Hence the British Uralite Company, Limited, settled temporary at Islington in a hut constructed of this material in order to show the building world the uses to which Uralite may be applied. In the hut we saw how Uralite can be veneered for panelling interiors, and how it can be painted, grained, and polished for house building purposes. Builders might find Uralite useful as a lining for walls and partitions in hospitals, asylums, and workhouses. For temporary erections Uralite will prove invaluable.

A very neat two-roomed "week-end" bungalow, composed of Connah-Wright's patent dovetailed corrugated metal sheeting, is the object-lesson presented by the Fireproof Partition Syndicate, of Adelphi. The features of the patent are seen at a glance. The sheets are formed into dovetailed grooves, which form a double key for any plastic material, and make the partition solid, as well as fire, sound, damp, and vermin-proof. Roofs are also made with this patent sheeting, the tiles being embedded in plaster. The partitions are only 2in. thick, and this is a great saving in a large building; while the fire risks and insurance are minimised. Fireproof floors are constructed on a similar principle. This patent is well worth the consideration of experts.

The floor space of the very artistic apartment of the Mosaic Manufacturing Co. (of Pentonville) is covered with Roman marble mosaic and parquetry. Within are examples of Venetian marble mosaic for public buildings, and of parquetry. Specimens are forward of Venetian marble mosaic with curved skirting and slabs for wall lining, and bits of Roman marble mosaic, showing considerable variety in treatment. This section appeals to the artistic taste of architects and decorators.

"Thezzotile" is domiciled in a nice room and in a special position to display the merits of the sanitary decorations furnished by the London Artistic Tablet Company. The wall and ceiling coverings are of enamelled zinc, which is damp proof and a germ killer; while the other wall decorations we saw were on enamelled metal. At all events, "Thezzotile" had a very attractive and withal cleanly appearance.

Patent earth closets for country districts are greatly favoured by the Local Authorities and owners of large works. We were glad to see that Moule's Patent Earth Closet Company were in the hall with models of all their excellent specialities. These closets should appeal to Sanitary Inspectors and public health officers as excellent appliances in districts where water is deficient. Indeed, the appliances of the company are well worth the attention of every village councillor.

Brass and copper work for engineers are the specialities of Wm. Hepton and Son, of Leeds; and they have registered their corrugated copper cylinders free from all loading, with bright polished top.

Architects and carpenters will appreciate the models of the new system of stairs patented by Mr. T. F. Wilkinson. In the new style the angle is designed to combine easier risers with wider treads than can be arranged on the ordinary system. The cottager will now obtain as easy a means of getting upstairs as his rich neighbour. In the model the hand-rails guide the passenger in the centre of the staircase, so that he places his left foot on the left-hand steps, and his right foot on the right-hand steps. There is one more riser on the left-hand side—looking upwards—than on the right-hand side, so that both the ascent and the descent begin with the left foot, as a soldier does in marching. This is a great improvement, and will prevent many accidents, cottage stairs being so steep and uncanny.

Drain-testing is of frequent occurrence, and the City of London Fireworks and Public Decoration Company (of 11, Poultry, E.C.) hold special patents for smoke-cases or rockets for that purpose. These smoke-cases are now in use by the London School Board, and the principal Corporations, District Councils, Sanitary Authorities, plumbers, &c. Many sanitary engineers speak well of them.

A useful sanitary appliance for removing obstructions in closet traps, drains, soil-pipes, and baths is Mr. A. T. Cooper's suction and vacuum pump. This appliance is used where pipes and drains are not blocked to keep them properly cleansed once a month, and for freeing pipes of obnoxious smells. It may be utilised for sudden flushing of drains, and for working on the outlets of any angle required.

The Patent Vulcanite Roofing and Asphalt Company exhibit specimens of their roofing, to which we referred at length at the last Exhibition. The models were much admired, and indeed they attracted as much attention as on the occasion referred to.

A most useful sanitary invention is the cone placed on top of the air-shaft of drains, as described by Mr. Wallace Cadman, of "Crossmyloof," Retreat-road, Westcliffe-on-Sea, Essex. When a wind pressure of 45 lb. to the inch is blowing, it often happens that the zinc or wire tops are blown off. Mr. Cadman's coned perforated covering is of cast iron, and has a tapered socket, and fits into the pipe. Consequently it never blows off, and will prevent nest-building in the pipe and increase the up-draught. Residents living in houses whose pipes are protected with this covering are perfectly secure against sewer gas entering through blockage of the ventilating pipe. Messrs. Thomas Holcroft and Sons, Limited, Wolverhampton, have undertaken the manufacture of the coned perforated covering.

Our readers are familiar with the properties of granite silicon plaster as prepared by the Granite Silicon Plaster Company. This speciality competes with ordinary lime and hair, and, though more expensive, is cheaper than cement plasters. It is favoured very largely by his Majesty's War and Post-office Departments, and is evidently in great demand. One feature is quick setting, the plaster never cracks, sets hard, and dries quickly. Builders should note these points.

The adamantine clinkers of Messrs. Towers and Williamson make an admirable solid sanitary pavement.

They are suitable for stables, coach-houses, yards, kennels, &c. The clinkers were used in the paving of the Royal Mews at Windsor, Sandringham, and Bagshot.

The Kingsland Steam Joinery Works sent several specimens of their manufactures, including closet seats, lavatory fittings, and bath taps, &c.

Aspinall's Enamel, of New Cross, was represented, a neat villa model, entirely decorated with the specialities of the firm.

Jetley's Wood Structures, Limited, had a grand model on exhibition, indicating the utility of their reversible patent structure wood paving. This paving when brought to the street in slabs, tightly joined together by special machinery, and fitted so that no single block can move, and the street cannot go into holes. The blocks are chamfered, and have a beautiful appearance, giving a foothold for horses and preventing slipping. The laying of a street with this new paving, which looks like tiles, takes only a quarter of the time necessary under the old system.

Models showing the application of asphalted roofing, felt, and slag work were exhibited by Messrs. McNeill and Co., of Bunhill-row, and it was a most attractive exhibit.

Bonsor and Co., of Brixton, exhibited a model, with hot and cold water laid on to illustrate the working of the patent "Century" expansion astragal. The firm had on the walls specimens of their patent "Century" lead sockets for rain-water, soil, waste, and ventilating pipes. These were made in various designs, and with ends suitable for soldered, expansion, or slip joints.

Messrs. Oates and Green, of Halifax, made good use of their space to make an effective display of their wares. These comprised bricks of all colours, washtubs, closets, lavatories, sanitary horse-mangers, and sanitary specialities for schools, factories, barracks, and public institutions.

The National Opalite Glazed Brick and Tile Syndicate had the same old diamond-shape office they exhibited two years ago. We understand the company have covered about seventeen acres with opalite tiles in the space of four years. This tile is a great favourite in artistic circles, and always possesses an increased reflection.

Messrs. H. J. and C. Mayor exhibited many specimens of their roofing and ventilated ridge tiles; and Candy and Co. made the most of their display of bricks, terra-cotta blocks, and sanitary stoneware pipes and fittings.

Messrs. James Blezard and Sons, of Padiham, had a show of builders' air grates, hot-water pipes, fittings, and boilers, also specimens of school furniture. The rainproof ventilator is not only the latest, but the leading builders' air brick. It is neat in appearance, and is made to set level on either brick or stone walls.

Special bricks for sewer-work were shown by Messrs. Geo. Tucker and Sons, of Loughborough, who had also in front some excellent specimens of terra-cotta bricks in red and buff, as well as red paving and roofing tiles.

The Somerset Trading Company had a small roof covered with their patent interlocking tiles, which are easily laid without nails, and may be utilised in exposed positions, as they are proof against rain and snow drift. Many bricks and tiles of various shapes and uses were displayed on this small but neat stand.

Shanks and Co. occupied the same bay as in previous years, and exhibited thereon their sanitary specialities.

Ripolin, Limited, had a grand display, showing the application of Ripolin to various materials. The firm exhibited a canvas which had been decorated with Ripolin, which requires no varnish, and also applied to a plaster freize. Doors and panels were treated with Ripolin and liquid gold, and the varied shades of the paints were well brought out on the panels. The stand was very neatly arranged. On one side was a table with many specimens of work and imitation mosaic, and on the other a small office entirely decorated with Ripolin. The firm received two gold medals at the Paris Exhibition.

The Rainwell patent lavatory basin was exhibited by W. F. Mason, Limited, of Manchester. It appears to be well adapted for hospitals, hotels, clubs, &c. The Rainwell requires no plug, washer, chain, lead trap, or overflow pipe, and, of course, the labour and expense involved by the old style is saved.

The Thames Bank Iron Company had a big show in their bay. There were boilers for warming purposes, and also for hot-water services to baths. Then we observed specimens of sanitary pipes and connections, manhole covers and frames, radiators and hot-water materials, rain-water pipes and connections, &c. All these goods were very well arranged, and afforded the visitor ample opportunity for examination.

Mr. H. Hart (of Stepney) had forwarded a nice assortment of his specialities. Every description of drain cleansing machines and tools were there; also brushes, tubes, flues, and pipes. Specimens of his patent spring lock joint were on view.

The Banks Fireproof Construction Syndicate, Limited, occupied some space with several models showing the patent fireproof floor, ceiling, and partitions. With Banks' patent ventilated floor, a current of air is continually passing between ceiling and joist, and is quite sound and fireproof. To prove the strength of the helical metal lathing (which is the only lathing made out of steel wire), about three tons of pig iron were placed on the top it. Specimens of the fireproof corrugated helical lathing and cement were on view, also fireproof partition, with samples of girder, column, and stanchion casing. The models of lift and staircase enclosures are very neat.

Enamels are used for baths and decorations about the house, and Messrs. James Price and Son, of Euston-road, offer "Chez Lui" for both purposes. They also supply metallic enamels and stains, decorators' varnishes, ready-mixed paints, dry colours, &c. The arrangement of the colours and their effect was somewhat attractive.

(*To be continued.*)

The Halifax Board of Guardians last week considered the proposal of the Halifax Corporation to erect a refuse destructor on a site close to St. Luke's Hospital, the buildings which have recently been erected by the Board of Guardians at a cost of nearly £100,000. In the opinion of the Hospital Committee, the destructor would be greatly detrimental to the interests of the inmates of the hospital, and would be a grave danger to the sick, and the Committee recommended the Board to take immediate measures to ensure the proposal being reconsidered, with a view to the destructor being placed in some more remote district. Mr. Balme, in proposing that the minute be referred back, contended that not the slightest smell would arise. Mr. H. Skelton seconded. A refuse destructor had been wanted in Halifax for years, and he could not see that it would be detrimental to the new hospital. Several members spoke in favour of the recommendation of the Committee, holding that if there were any likelihood of anything detrimental to St. Luke's Hospital, another site should be found. The amendment was defeated by a large majority, and a further resolution was agreed to, setting forth the objections to the refuse destructor being placed on the site proposed by the Corporation, with the addition:—"The Board, at the same time giving notice to the Corporation that if the destructor is placed near the hospital, they will have to take steps to protect the interests of the sick as they may deem advisable."

THE SUPERVISION OF DAIRIES, &c.

By James Robert Kaye, County Medical Officer, West Riding of Yorkshire.

The first requirement of Local Authorities aiming at the proper sanitary supervision of cowsheds is the adoption of Regulations under Article 13 of the above Order (see the Model regulations recently issued by the Local Government Board). Experience has proved that those "Models," owing to their necessary general character for the whole country, do not afford that practical assistance to Sanitary Authorities and their officials which is desirable. Absence of reasonable uniformity of action in this matter is conspicuous throughout the West Riding, and this is doubtless due to the want of more definite principles.

An attempt to overcome these difficulties has induced the West Riding Sanitary Committee to authorise the preparation of the following suggestions, which may be regarded only as supplementary to the Model Regulations, not binding in law, and merely indicating what the Sanitary Authority should aim at in promoting the sanitation of cowsheds and the healthiness of the cattle housed therein.

(1) *New buildings, or premises proposed to be newly occupied as cowsheds.*—Under Article 7 (2) of the Order the Sanitary Authority are entitled to one month's notice in writing before any such premises are newly occupied as cowsheds. Before passing the plans for any new cowshed the Authority should see that the materials proposed to be used, and the details of construction, are in accordance with the building bye-laws of the district.

Construction.—The walls should be covered internally to a height of 4ft. 6in. with a smooth impervious material, so as to provide an easily washable surface. The roof should be externally covered with slate or tiles (not corrugated iron, because of the difficulty in regulating temperature, &c.). Gutters or spouts should be provided to carry the rain water to a fall pipe, which should not discharge into the midden but into the surface drainage system so as to avoid dampness of walls and foundations. In places where other water supply is not convenient the rain water might be conducted into a cistern, and used for cleansing the manure channel, floor, &c.

The distance of the cowshed from dwelling-houses, schools, workshops, or public buildings should not be less than 25ft. The cowshed should have two sides at least free from obstruction, so as to admit of free lighting and ventilation. The building should be not less than 8ft. high internally at the eaves. The width or distance between the front and back main walls should be sufficient to allow for a feeding passage between the wall and manger, a trough manger and hayrack, stall, a manure trench, and a cleansing passage. For example, 3ft. 3in. to 4ft. for the passage between the wall and manger; 2ft. for the trough manger and brickwork; 5ft. 9in to 6ft. for the stall; 2ft. to 2ft. 6in. for the manure trench, which should be 3in. deep and carried from one end of the shed to the other; 5ft. to 5ft. 6in. for the cleansing passage.

Where a double row of stalls is wanted, the section might be the duplicate of the above with the exception that the raised passage in the centre for general use might remain at 5ft. 6in. in width. The width of each stall should be about 4ft. for a single cow, and from 6ft. 3in. to 7ft. for a double stall.

The Local Government Board have advised that those cowsheds where the animals are only taken out for drinking purposes cannot be interpreted as coming under Part I. of the Model Regulations, and therefore are not exempt from the requirements of Part II. as to cubic space.

Lighting.—Light should penetrate every nook and corner. To obtain this every cowshed should be provided with windows, or lights in the roof. Three square feet of window space per cow is suggested as a good working average.

Ventilation.—The windows should be so constructed that one-half will open inwards so as to admit air and deflect it upwards above the animals. It is well to provide a number of permanent openings in the walls, so designed that the external aperture is four or five times smaller than the internal orifice. These are placed at about 7ft. above the floor, and the air which enters by such cone-shaped openings becomes readily diffused. Another simple method is to place 2in. tile pipes in the wall near the eaves with 2in. of rise from the outside inwards. Outlets for the egress of foul air should be provided in the roof—or, if there is a loft or ceiling a chimney is desirable. Louvre ventilators may be employed, or the ridge may be elevated and provided with outlets at proper intervals. Roughly speaking, 30 to 40 square inches of inlet area per animal is advisable, while the outlets should be at least equal to the inlets, or, preferably, a little more. The external door should be divided crosswise, so that the top half may be left open when desired. Increased cubic space is of little value without proper ventilation.

Flooring.—The floor of a cowshed should not in any part be below the surface of the ground. It should be properly laid and graded so as to take away all liquids falling upon it. Concrete covered with cement properly furrowed is perhaps the best flooring, because no filth can accumulate in the joints as in ordinary paving. If flags or setts are used they should be laid on a bed of concrete and jointed with cement.

Drainage.—The floor of the standing should have a fall of 2in. or 3in. from the manger to the manure channel, whilst the floor of the channel itself should have a fall outwards of at least ½in. in cross section and a fall longitudinally of ½in. per single stall, so as to drain away the liquids; the floor itself should have a similar fall. The channel should discharge on to a trapped gully outside the cowshed leading to a liquid-manure tank. No covered drain should exist inside the cowshed.

Midden.—A proper middenstead should be provided in accordance with the bye-laws as to prevention of nuisances. Its walls should be made of hard impervious material, and the roof should be supported by means of piers, thereby providing for adequate ventilation and the exclusion of rain. The flooring should also be impervious.

Yard.—The yard and approaches to the cowshed should be properly formed, graded, and paved, to take away the surface water, which should not discharge into the midden.

Manger.—A half-round salt-glazed trough, rising 12in. or 15in. above the floor, is much superior to a wooden tub. A hay-rack immediately over this trough obviates the placing of fodder on the floor. Neither the foddering passage nor any part of the cowshed should be used for the storage of foods. A proper food store should be provided.

Water.—Where the water supply is not derived from a public source, great attention should be given to its protection.

General.—No poultry or pigs should be kept in any part of the cowshed, and it is desirable also that horses and calves should be excluded.

A thermometer in the cowshed is useful.

(2) *Existing cowsheds.*—There are no doubt some buildings used as cowsheds which were not originally constructed for that purpose, and which cannot, except by reconstruction, be made to satisfy even the most elementary hygienic requirements. On the other hand, there are a great number of existing cowsheds which, although not fulfilling all the conditions set forth above, may yet be rendered workable by providing them with

abundance of light, efficient ventilation, impervious flooring, and an adequate supply of water. These essentials can be secured, and should be insisted upon by the Sanitary Authority.

(3) *Register.*—A register should be kept by every Sanitary Authority in which to record the results of periodical inspections. No cowshed should be used for housing a greater number of cows than is specified on the register. Amongst other information locally desirable, the following items are suggested:—(1) Name and address of person registered; (2) situation of premises; (3) owner of premises; (4) number of sheds with size—length, width, height, and cubic space per cow; (5) number of cows in each shed; (6) flooring—material and condition of; (7) walls, material—rough or smooth; (8) water supply—source, position; (9) lighting—number and size of windows or other lights; (10) ventilation—number and size of permanent openings, number and size of openings capable of regulation; (11) midden—distance from cowshed, open or covered, disposal of liquid manure; (12) yard—formation, paving drainage; (13) cleanliness—general condition of floors, walls, midden, yard; (14) general drainage system; (15) disposal of drainage.

LEAD POISONING AND SERVICE PIPES.

The following report bearing upon the prevalence of lead poisoning from water supplies in the district has been presented to the Halifax Town Council by Dr. J. T. Neech, Medical Officer of Health:—

On February 1st of this year I received a communication from Mr. Paskin, the Waterworks Engineer, saying, that it had been reported to him that lead poisoning was frequent in Northowram. I had already had cases reported to me from Southowram Ward, consequently I put myself in communication with all the medical men who practice in Northowram, and also visited the district myself. From the replies I received, and from what I saw myself, I came to the conclusion that the reports were true. One doctor said, lead poisoning had been endemic in Northowram for several years, and another that he thought that three people out of every four would have the blue line round their gums, which is indicative of the presence of lead in the system.

The cause of the plumbo-solvent power of water is the presence of certain peaty acids in solution in the water, and in order to judge of its action on lead, it is of no use to obtain samples of the water from the service pipes and estimate the amount of lead therein, because these pipes hold only a small quantity of water, they may have recently been emptied, or the person in taking a sample throws away that which contains the lead in rinsing out the bottle. The only way, then, to obtain any definite and reliable information as to the plumbo-solvent power of any given water is to immerse lead or lead piping therein for a given period, and then estimate the amount of lead dissolved by the water during that period. This is what has been done in the following experiments:—Half-inch lead piping has been used, and was immersed for a period of one hour. All the calculations are in parts per 100,000.

Through Mr. Paskin, samples of the reservoir water were taken, and the average result of several analyses showed—acidity, 1·01; lead dissolved, ·56.

I also procured several samples of water, as supplied to the Northowram and Southowram Wards, and the average results of the analyses of these samples gave:—

Acidity.	Lead dissolved.
·7	·18

Whenever the acidity of a moorland water reaches ·5, its plumbo-solvent action begins to reach the point of danger to health, and as the acidity rises beyond ·5, the danger increases proportionately. A water, then, giving the above results is dangerous to health, and the foregoing figures are the average of several estimations, in which the acidity varied between ·63 and ·78, and the lead dissolved, between ·15 and ·20, hence the water at times is even more dangerous, and this danger does not exist merely in theory only, but is practically demonstrated among the inhabitants of Northowram. It is true this same water supplies Southowram Ward, and other parts of the Borough, in which there is not much lead poisoning at present, but this is accounted for by the use of longer lead service piping in the Northowram district.

I had several consultations with Mr. Paskin on this subject, and he informed me that the water at Ogden was treated with chalk before distribution. This accounts for the difference in the acidity, and the lead dissolved by the water from the reservoir, and that distributed to the consumers, as shown by comparing the foregoing figures.

I visited the Ogden reservoir and inspected the methods in use there for treating the water. The water, I find, passes through a filter for the purpose of removing all suspended matter therefrom before entering the mains. The chalk is put at intervals into an iron tank, which is divided into two compartments, and is mixed with water in one of the compartments, which water is supplied through perforated piping under pressure. This serves to keep the chalk suspended in the water. The water with the chalk in suspension is then carried by a pipe and mixed with the water flowing from the reservoir, a few feet before it enters the filter.

Chalk, which is carbonate of lime, is quite insoluble in water, hence it is quickly removed therefrom again by the filter, and is therefore not in contact with the water sufficiently long to reduce the acidity below the dangerous point. Had the water in the reservoir a good quantity of carbonic acid in solution the chalk would have been more soluble therein, and probably would have had the desired effect.

These being the facts of the case, I came to the conclusion that it was necessary to supply an alkali that was more or less soluble, in order that it might pass through the filter and neutralise the acidity of the water. Lime is soluble in water in quantities varying from 80 to 90 grains per gallon. I made some experiments with it, and chalk and the two substances combined seemed to give the best results. Hence I decided to add lime with the chalk that was already being put in.

Mr. Paskin had the other compartment of the iron tank at Ogden fitted up according to my request, and on February 28th last we went there together and started the lime process. Consequently since the above date, lime water holding in solution about 23 lb. of lime (about ·75 grain to the gallon) has been discharged into the mains with the chalk solution in suspension in the twenty-four hours.

I have since had several samples of the water as supplied to the consumers taken on different occasions from Northowram, Southowram, and Claremont, and the average result of the analyses thereof gave:—

Acidity.	Lead dissolved.
·31	·037

I am of opinion that these results are highly satisfactory, and if the water be maintained at this standard there will, I think, be no danger of further lead poisoning. The analyses were performed by Mr. Akroyd, the Public Analyst.

The first lady medical practitioner to receive the decoration of the Red Cross in the present reign is Dr. Lillie Savile, whose eminent services under fire at Pekin will be fresh in the public remembrance.

National Health Society.

OFFICIAL TRANSACTIONS.

Examination for the Diploma.—On Tuesday last an examination on "Human Anatomy and Physiology" (for the diploma of the Society) was held at 53, Berners-street, W., by D'Arcy Power, F.R.C.S. The following ladies were successful in reaching the required standard:—Miss E. Olliff, Miss G. D. Bevan, Miss G. Looker, Miss L. Spiller, Miss I. Cox, Mrs. Carol Kelsey, Miss Hall Hall. The first five mentioned of these ladies have now completed their training for the diploma, having satisfied the examiners in all the required subjects.

Elementary Examinations in Oxford.—We have received a most satisfactory report of the result of the examination recently held in Oxford after Miss Hall's work in the county. The examiner says:—"This is on the whole the best class of candidates that I have yet examined. In some cases the written work was of a very high order. There were only one or two who barely passed. They were all successful, and I think much credit is due to the teacher in procuring such average excellency. The practical work was also good."

ASSOCIATION OF NATIONAL HEALTH WORKERS.

The annual course of lectures organised by the Association of National Health Workers, and given in the rooms of the National Health Society, commenced on Monday evening, May 6th. Mrs. Latter (*née* Miss de Pledge), late matron of Chelsea Infirmary, lectured on "Nursing as a Profession for Educated Women." Mrs. Latter weighed carefully the advantages and disadvantages of nursing as a profession, and discussed the different merits of general hospital and Poor Law infirmary training, the methods adopted by different hospitals of admitting probationers for training, the various scales of remuneration to nurses during their training, registration of nurses, necessity of a three years' training, &c. &c. The contrast drawn between the position of a nurse fifty years ago and her status, work, and efficiency at the present time was particularly striking.

On Tuesday afternoon at 3 p.m., Arthur Newsholme, Esq., M.D. (Lond.), D.P.H., Medical Officer of Health for Brighton, lectured on "The Methods of Preventing the Spread of Disease in Connection with Social Life." This lecture was exceedingly practical and useful.

At 5.30 p.m., on the same afternoon, Miss Alice Busk lectured on "Women as Sanitary Inspectors." As it is hoped that these lectures will be fully reported later, they will not be further summarised in this column.

Pudsey.—The annual report issued by Dr. W. L. Hunter, Medical Officer for Pudsey, gives the population of the borough as 14,909. The birth-rate for the year has been 25·3 per thousand, and the death-rate 14·9. A rapid decrease in the death-rate has been going on since 1880; but this has been more particularly noticeable in the zymotic and phthisis death-rates. There has been at the same time, however, an equally steady decline in the birth-rate, from 46·31 in 1837 to 25·3 in 1900. The Doctor compliments the Council on the good work they have done in recent years, and recommends more energy in scavenging, in clearing away insanitary dwellings, in the improvement of private streets, in the adoption of the water-carriage system, and in the provision of public baths and a public slaughter-house. The report is illustrated, and contains interesting statistics as to mortality and population since 1837.

LAW CASES.

Trade Refuse in Sewers.

An important appeal came before the Master of the Rolls, Lord Justice Vaughan Williams, and Lord Justice Romer last week in the Court of Appeal. It was the case of the Attorney-General on the relation of the Sevenoaks Rural District Council and the Sevenoaks Rural District Council *v.* Whitmore, and was an appeal from a judgment of Mr. Justice Mathew. The relators and plaintiffs were the Local Sanitary Authority for the parish of Edenbridge, and the defendants, Messrs. T. and H. Whitmore, were the owners of a tannery in that parish.

The plaintiffs claimed an injunction to restrain the defendants from causing or permitting the effluents from their tannery to flow into the sewers of the plaintiffs, on the ground that such effluents were of so offensive and dangerous a character that they caused the effluent flowing from the plaintiffs' sewage farm into the river Eden to be a nuisance to, and injurious to the health of, the inhabitants of the parish of Edenbridge and the persons living near the river Eden. The plaintiffs further contended that the tannery effluents contained free alkalinity to an extent which rendered them a liquid which would "prejudicially affect the application to land" of the sewage matter conveyed along their sewers, within the meaning of Section 7 of the Rivers Pollution Act, 1876 (39 and 40 Vict., c. 75), and that consequently they were not compelled to receive such effluents into their sewers. The defendants contended that the plaintiffs were bound to continue the admission into their sewers of the effluents from the tannery, and that the nuisance, if any, was caused by the inefficient state and unskilful management of the sewage farm: and they alleged that the tannery effluents were as capable of being dealt with by bacterial treatment as ordinary sewage, if the sewage farm were properly managed. It appeared that in 1875, when the Local Authority constructed a system of sewers leading to settling tanks and thence into the river Eden, the defendants had received a notice requiring them to connect their tannery with the sewers of the Local Authority, which they had done. In 1886 the present system of sewerage was constructed; and, before connecting themselves with the new system, the defendants, at the request and under the supervision of the Sanitary Authority, erected settling tanks upon their own premises. Upon the completion of this work the Sanitary Authority agreed to admit, and admitted, the tannery effluents into their sewers. Dr. Voelcker and Mr. Thudichum were called on behalf of the plaintiffs, and stated that, in their opinion, the tannery effluent contained alkalinity to so great a degree that a liquid resulted which prejudicially affected the application to land of the sewage matter conveyed by the plaintiffs' sewers. Mr. Strachan, Mr. Frank Scudder, and Mr. Santo Crimp, who were witnesses for the defendants, were of opinion that the effluent of the tannery, in which no chemicals other than vegetable acids and lime were used, in no way prejudicially affected the application of the sewage to land, inasmuch as a considerable quantity of the free alkalinity was reduced by carbonic acid from household sewage in the plaintiffs' sewers and the settling tanks at the sewage farm. They also considered that, owing to the sewage farm being on a clay soil and under-drained, the sewage matter found its way through the cracks in the soil into the under-drains, unaffected by the bacteria on the surface, and so passed in its crude state into the river. The action was tried before Mr. Justice Mathew, sitting with Mr. Baldwin Latham, C.E., as assessor. The learned Judge gave judgment for the defendants. The plaintiffs appealed.

Mr. Witt, K.C., and Mr. Morton Smith, appeared

for the plaintiffs; Mr. Dickens, K.C., Mr. G. F. Hohler and Mr. C. M. Pitman, for the defendants.

The Court, without calling upon counsel for the defendants, dismissed the appeal.

The Master of the Rolls said he had come to the conclusion after reading the whole of the evidence that it was impossible to say that the judgment of Mr. Justice Mathew was wrong. The real cause of action in this case was founded on Section 7 of the Rivers Pollution Act, 1876. That section conferred a benefit on persons carrying on trade—namely, a right to drain into the public sewers. It enacted that "every sanitary or other Local Authority having sewers under their control shall give facilities for enabling manufacturers within their district to carry the liquids proceeding from their factories or manufacturing processes into such sewers. That was a statutory right given to manufacturers. But it was subject to a limitation. The section proceeded, "Provided that this section shall not extend to compel any Sanitary or other Local Authority to admit into their sewers any liquid which would prejudicially affect such sewers or the disposal by sale, application to land, or otherwise, of the sewage matter conveyed along such sewers." Here the plaintiffs, who were a Local Authority, said that the defendants, who carried on the trade of tanners, although they had a *primâ facie* right to drain the liquids coming from their tannery into the public sewers, yet ought not to be allowed to do so because those liquids were injurious to the application to land of the sewage matter conveyed along the sewers. They said that the effluent from the tannery was such that when it came on to their sewage farm it killed the microbes which otherwise would have got rid of the impurities in the sewage. The whole issue was whether that was true. There was a large body of evidence given at the trial on one side and on the other, and that evidence was very complicated; the expert witnesses who were called not only giving evidence quite inconsistent with one another, but some of them giving evidence in cross-examination which was quite inconsistent with what they said in examination in chief. The defendants' point was that the cause of the microbes being killed was not the effluent of their tannery, but the method which the plaintiffs adopted of managing and working their sewage farm. Mr. Justice Mathew considered that point, and thought that it was made out, and he gave judgment for the defendants. There was no ground whatever for interfering with his decision.

The Lords Justices delivered judgment to the same effect.—*The Times.*

Liabilities of an "Owner" to abate Nuisances.

In the King's Bench Division, of the High Court of Justice, the Lord Chief Justice of England and Mr. Justice Lawrence had before them the case of Broadbent *v.* Shepherd. An appeal by way of special case from the decision of justices for the West Riding of Yorkshire, on a complaint laid by the appellant, on behalf of the Castleford Urban District Council, against the respondent, as the statutory "owner" of certain premises in the district, and alleging failure on the part of the respondent to comply with a notice served on him under Sec. 94 of the Public Health Act, 1875, requiring him to abate certain nuisances on the said premises.

The complaint originally came on before the justices on June 27th, 1900, when it appeared that the nuisance existed and was due to structural defects, but that the respondent was a mere rent collector or agent for the real owners of the premises. The justices were of opinion that though the respondent was "owner" of the premises within the definition of that term in Sec. 4 of the Public Health Act, 1875, it was not the intention of the Act to create two ownerships under Sec. 94, and that the definition of "owner" did not apply to the interpretation of that section; and they therefore dismissed the complaint. On the application of the appellant, they, however, stated a special case on the point for the determination of the High Court. On November 15th, 1900, the High Court ordered that the decision of the justices should be reversed, and remitted the case to the justices with an intimation that a rent collector or agent is an "owner" for the purposes of Sec. 94 of the Public Health Act, 1875. On December 5th, 1900, the complaint, having been reinstated in accordance with the decision of the High Court, again came on for hearing. It then appeared that the respondent had, since the last hearing, resigned the agency of the property. The justices were urged by the appellant to make an order on the respondent to abate the nuisance. They, however, were advised that they had no power to make an order on the respondent, on the ground that such an order can only be made on a person who is an "owner" of the premises when the order is made. They accordingly dismissed the complaint, subject to the present case.

Mr. Macmorran, K.C., and Mr. Scholefield appeared for the appellant; the respondent was not represented.

The Court allowed the appeal.

The Lord Chief Justice said that when the case was originally before the Court, consisting of Mr. Justice Kennedy and himself, the Court had held that the justices ought to have made the order, because the person against whom it was sought was "owner" of the premises within the definition. He would assume that that order would have been an order to abate the nuisance within a given number of days. What had happened was that at some time after the first hearing before the justices the agent had ceased to be agent. If the sole object of the order sought were to obtain a personal remedy against the indivdual, though even in that case he would not express the opinion that an order could not he made, different considerations would arise. In that case it might be said that the order would be a mere empty order and ought not to be made. But when Secs. 96, 98, and 104, were looked at it appeared that one object of the order, among others, was to found the right of the Local Authority to enter the premises, do the work, and recover the expenses from the person responsible. The justices had originally jurisdiction, as the Court had decided, to make the order on the agent; and, in his Lordship's opinion, when the case went back to them they should have made the order they ought to have made in the first instance, unless, as was not the case, that order would have been wholly nugatory. The case must be remitted to the justices accordingly.

Mr. Justice Lawrence concurred.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

The post of City Engineer to the Corporation of Cape Town, South Africa, which is again vacant, and for which applications had to be sent by May 2nd is, I find, being considerably sought after by English engineers. The salary is £1000 per annum, which, on the face of it, appears tempting, but it should be borne in mind that owing to the high cost of living, house rents, &c., this amount is not nearly equal in value to a similar salary in England. I think it is due to candidates for the office that they should be aware of the fact that the conditions under which the City Engineer of Cape Town holds his appointment are the reverse of being satisfactory or bearable. The members of the Corporation are mostly of Dutch descent, and are, I regret to say, intolerant and highly inconsiderate to officials, and their views of their own powers and the

functions of the Engineer are singular in the extreme. Few engineers can endure the strain of worry and disagreeable work under the Cape Town Municipality, and in evidence of this it should be observed that the appointment is vacant at intervals of every two or three years.

At this period of the year, the members of Local Authorities influenced by the requirements of their constituents or the advent of summer are infected with a zeal for the establishment or enlargement of public baths and discuss the question at Council meetings until the season—when the British youth yearns for swimming— is over, when it is adjourned until the succeeding season comes round. Occasionally, of course, the result of the controversy is that public baths are erected, when the Surveyor is required to prepare plans for such buildings, and superintend their erection. It must be said that the average Councillor is rarely an enthusiast for public baths, owing to the fact, which is indisputable, that such baths are never self-supporting, but the cost of their maintenance always becomes a charge on the rates. Of course it is argued that they are beneficial from a sanitary point of view. To some extent this is true, but not to the degree which is generally advocated. Moreover, if Local Authorities are to be made responsible for the cost of maintenance of every *quasi* sanitary measure, the end will never be in sight. Inasmuch, however, as the practice of providing such baths at the expense of the rates has been established now in a considerable number of towns, it has to be generally followed in all urban districts.

For the information of surveyors and architects, I may state that the literature on the subject of public baths is exceedingly small. There is only one independent volume published, which is Allsop's "Public Baths and Wash-houses," price 7s. 6d. It is sensibly written, and contains valuable suggestions which ought to be fully considered by every architect who has to design such buildings. It does not, however, as might be expected at the price, contain many plans, and those which are given are applicable to large towns only.

One of the cheapest public baths for small towns which I remember to have seen is that built a few years ago at Market Harborough by the District Council from the designs and under the superintendence of their excellent Surveyor, Mr. Harold G. Coales. The area of the bath is 75ft. by 25ft., and four slipper baths are also provided, the total cost only reaching about £2300. I commend this building as a model to surveyors who have to design baths for any town with a population under 20,000.

The difficulties of providing cheap housing accommodation for the rural population is nowhere more keenly felt than in the southern and eastern counties of England; and it appears that in Essex especially, brick-built houses, if constructed according to the requirements of the Model Bye-laws as to new buildings could not be let to tenants able to pay such a rent as would yield an average rate of interest to the building owner, so low are the incomes of the wage-earning class. Cottage building is in consequence at a standstill in those districts in which the Model Bye-laws are in force and gross overcrowding exists in old properties.

The Rural District Councils are endeavouring to meet the difficulty by obtaining the approval of the Local Government Board to building bye-laws which shall permit the erection of cottages built of timber framing, and a draft of such bye-laws has been sent to me. I believe that Messrs. Dewhirst and Keywood, the Surveyors to the Chelmsford Rural and the Maldon Rural District Councils respectively, are jointly responsible for the preparation of the proposed bye-laws, and I may here observe that they are to be congratulated on the care and discrimination which they have exercised in the work.

The most important clauses introduced are those having reference, of course, to dwellings built of timber framing. These are classed as "practically exempted buildings," and are to be exempt from the operation of the clauses relating to thickness of walls, mortar, incombustible materials, height of storeys, party walls, &c. These clauses provide that "Any building not exceeding in area 700 square feet and not exceeding 20ft. in height, measured from the top of the footings to half the vertical height of the roof, built of timber framing not less than 4in. by 3in., properly put together and resting on brick footings not less than 12in. out of the ground, and similar in every respect to the footings required for a 9in. external wall, the timber framing of such building to be covered externally with weather boarding, lath and plaster, expanded metal and plaster, tiles, or corrugated iron, and covered internally with lath and plaster," and "any building not exceeding an area 700 square feet and not exceeding 20ft. in height, measured from the top of the footings to half the vertical height of the roof, the external walls of which so far as the first storey shall be of brick, stone, or other hard and incombustible materials, properly bonded and solidly put together, and not less than 9in. in thickness, the second storey of which is constructed of timber framing, covered with weather boarding," &c., as in the previous clause.

With these clauses are provisos that the term "building," as used above, shall not comprise more than two dwelling-houses, and shall be distant at least 15ft. from any adjoining lands or premises, and also that in every case where the building comprises two dwelling-houses the party wall shall be of brick or stone not less than 9in. thick throughout, the party wall shall project 1in. beyond the face of the external walls, and no timber or woodwork shall be placed within 4½in. of the centre of such party wall.

These clauses, it will be seen, are a radical departure from the present "models," and it remains to be seen whether the Local Government Board will approve them. One would suggest that the distance of 15ft. should be extended so as to prohibit such buildings being erected within 15ft. of any street, and it appears to me that the party wall of such building which has to be constructed of brick or stone may be put together as "dry walling," that is, without mortar or cement, as such buildings are proposed to be exempted from the operation of Clauses 12 and 13, which apply to mortar, &c. This is doubtless an inadvertence which should be corrected before final approval. It is also undesirable to prescribe the materials in the manner suggested, as there are several other methods of covering the timber framing, and doubtless many others will be forthcoming which may be superior to those suggested, but which could be prohibited under the bye-laws as drafted. Inasmuch, too, as both steel and iron framing are being introduced for walls of houses, partitions, &c., which is much superior to timber framing, provision should be made for the alternative use of such material.

I hope to be able to advert to the subject in the next issue. There are numerous rural surveyors who are deeply interested in the alteration of such bye-laws, and to those I may state that Mr. Dewhirst, Surveyor to the Rural District Council, Chelmsford, or Mr. Keywood, of Maldon, will, on application, forward a copy of the draft bye-laws.

Senex.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

A LESSON TO RAILWAY COMPANIES.

IN rejecting the London and North-Western Railway Company's Bill last week, the House of Commons read a severe lesson, not only to it, but to all other railway companies concerned in the execution of railway works involving the displacement of population. The companies will now perhaps understand that Parliament expects that its intentions with regard to re-housing, and not merely the strict letter of the law, will be complied with. The course adopted was a very unusual one, and may no doubt cause temporary inconvenience to certain localities, but the effect of the lesson will be most salutary. The question arose over a proposal in the Bill before the House to take power to acquire land in Hammersmith for purposes of extension. At once Mr. Hay, the member for Shoreditch, Hoxton, brought up the evasion by the company of their obligations to re-house the people displaced by their operations under former measures; and though he was not allowed by the Speaker to enter into the past misdeeds of the company, as not being germane to the present Bill, he had the feeling of a very large section of the House with him in proposing the rejection of the Bill as a mark of disapproval of the company's conduct. The company, it was made clear by Mr. Ritchie, has been in conflict with the Home-office as to their re-housing obligations. As Mr. Macnamara aptly reminded the House, Mr. Ritchie had just been forced to threaten the company with a writ for £16,000 for its persistent evasion of these obligations. The contention of the company is that in providing new dwellings for those cleared away for railway purposes, it is not bound to provide dwellings suitable to the class disturbed. Mr. Ritchie therefore suggested that a Committee might be appointed to consider the model clause relating to the housing of the working classes, in order to increase its stringency. The proposal met with unanimous approval, and obtained the assent of the promoters of the railway company's Bill. The promoters also acquiesced in Mr. Ritchie's suggestion that the obnoxious Hammersmith clauses should be withdrawn, but even this concession was not sufficient to allay the deep feeling of dissatisfaction in the House with the company's past record. The member for Battersea, as might have been expected, was characteristically caustic. "The Home Secretary," said Mr. Burns, "seems to have been wrestling with wild beasts at Ephesus." ("At Euston," interpolated Mr. T. W. Russell.) The directors, he said, had defied the Home Secretary. "Not I," interrupted Colonel Lockwood. Mr. Burns's retort was prompt. Precisely, he said, Colonel Lockwood was a soldier and understood strategy, but the House was only interested in one kind of strategical movement on the company's part, and that was a movement to the rear. On a division the Bill was rejected by a small majority. The action of the House could not be defended as logical. The Bill itself, when lightened of the objectionable clauses, was not intended to be condemned. The vote was simply intended as "a protest against the domineering of the great railway companies," who in the plenitude of their power think they can disregard the intentions of Parliament with regard to the housing of the working classes.

Child Labour in Dundee.

MR. ROBSON'S Half-Timers Act is to be followed by a measure having a similar object for Scotland. The Government took up the question of raising the age in Lord Balfour's Education Bill last year, which had unfortunately, owing to lack of parliamentary

time, to be dropped; and now Mr. Pirie brings forward a private member's Bill with the same end in view. Mr. Pirie's Bill—which was read a second time last week—is full of defects and anomalies; but the broad principle on which it is based, that the school age should be raised, obtained the hearty support of both sides of the House. It is, indeed, unexceptionable. The Lord Advocate explained, in the course of the debate, that the position of Scotland and of England on the half-timer question was quite different. Except in Dundee and Paisley, the system had practically disappeared, and it was fast dying a natural death. But in Dundee, the most important centre of the half-time system in Scotland, where the children are employed in the jute mills and factories, the condition of things appears to be particularly bad. Mr. Tennant quoted from the report of Mr. Wilson, the Inspector of Factories, who came to the definite conclusion that these children in Dundee were perhaps more diminutive than were to be found in any part of the country. They lost flesh and colour. They put on little weight, and grew very slowly. And the worst of it is that in going into the mills at this early age they have not even the advantage of learning a trade; for at the age of fourteen or fifteen they leave the factory, and go to swell the ranks of casual labour; and at sixteen or seventeen they often have no employment at all. It was a most sombre picture that Mr. Tennant drew, unrelieved by a ray of light. He stated that the situation in Dundee was so bad at present that it had attracted the attention of the manufacturers, the Medical Officer of Health, and the Town Council, who, he understood, were going to take the question in hand. The state of things has also other consequences equally disastrous. Mr. Tennant explained that the result of the children leaving the mills sapped of their best vital power and without having learned a trade was that the number of unemployed men in Dundee living on their wives had become a byword; and, further, that there was a large amount of mortality among women in Dundee owing to this fact, that their husbands could not or would not work, and that the burden of the work consequently fell on their shoulders. The situation he characterised to be almost beyond the dreams of degeneracy, full of gravity and danger to the State. Such, then, are some of the results of the half-timer system where it has been in full force. The system is doomed, and the sooner it is helped to its grave the better.

Re-vaccination in Glasgow.

Some interesting figures in connection with small-pox epidemic in Glasgow were furnished at a meeting of the Town Council last week. The vaccination obstructionists—happily a very insignificant minority—have been most persistent in their efforts to throw discredit on the measures adopted by the Health Department. One of them, Mr. Shaw Maxwell, has been pressing for returns to show the number of patients admitted to hospital who had been vaccinated, and at the meeting referred to he drew attention, with an air of triumph, to these returns. They showed that of the admissions during the past month 119 had been vaccinated, 6 were unvaccinated, 4 were doubtful, and 19 had been re-vaccinated. He referred to these figures as disproving a recent statement of the Lord Provost, made on the authority of the Medical Officer, and previously quoted in these columns, that there had been absolutely not a single case of small-pox where the patient had been re-vaccinated, whereas the returns showed that there had been at least 19 such cases. The Lord Provost had no difficulty in at once putting him right. In every one of those 19 cases re-vaccination had taken place within the period of incubation, and therefore the figures bore out exactly and literally the Medical Officer's former assurances. Mr. Dick, Convener of the Health Committee, mentioned the interesting fact that they had actually re-vaccinated 302,000 persons since January 1st, and he said he had been congratulated on all hands that the city of Glasgow was in a position no other community in the kingdom was in. The record is certainly a very creditable one.

Quiet Work at Bradford.

We congratulate the Bradford Sanitary Association on the issue of its nineteenth annual report. Like kindred organisations it does its work quietly, but none the less effectively. In the year reported upon special attention has been given to one particular phase of the food question. "Our object," says the report, "is to improve the food of the people. Food is that necessity of life which is paramount to all others. It is absorbed in three forms; that is, we take solid food, liquid food, and air food. Poison may enter into any one of our three foods, and terminate our existence more or less summarily; reason would say, it matters not which. Yet such is our unreason that the death of a few unlucky beer-drinkers, to be counted by units, who have loved their cup too well and have imbibed deadly poison with it, and whose lives are but as a few drops in the tide of death, creates greater consternation than the perennial flood which, day by day and year by year, carries down its thousands of victims from the poisoned air food we consume. On a fair computation, not more than one householder in a hundred regards the purity or impurity of this kind of food as of the least personal importance, and even of this select few three-fourths cannot carry their scruples beyond the four walls of their own dwelling; the air of their places of business is indifferent to them. It is this air food we wish to improve. We wish to rivet the attention of our neighbours not only on the penalty of disease and death we pay for poisoning it, but on the lack of refinement it involves. Until we are as careful about our air food as we are about our bread and water, we cannot claim to be much superior in cleanliness to the humblest creature that lives in the open air." How true this is every health-worker knows. The utter carelessness of many to the purity of their surroundings,

is the greatest difficulty met with on every hand and when such are persuaded of the necessity of fresh air in the home and the workshop, all other advance becomes easy.

The Women's Memorial.

We suppose it is inevitable that a number of appeals must be issued for the establishment of memorials to our late beloved Queen. The Lord Mayor, of course, would desire that all should give their support to the great national tribute, on behalf of which he appealed a few weeks ago. But there are those who would rather support a movement for the alleviation of suffering than the erection of an immense monumental structure. To such the proposals made at the meeting held last week at the residence of the Marquis of Londonderry should come with irresistible force. No better work has ever been done than that which the late Queen inaugurated when she handed over the women's jubilee offering for the establishment of the Jubilee Institute of Nurses. How greatly this institute has prospered may be gathered from one fact alone—that last year its nurses paid no less than four million visits to the sick poor in all parts of the kingdom. But its good effect is not confined to its own work. Other institutes have been established, and the country is fast being covered with a great network of nursing organisations, which is doing more than anything else to prevent suffering and give help to the helpless. We know of no better means to commemorate the life of Victoria the Good than the strengthening of this beneficent work. Most branches are able to collect enough funds for the carrying on of their operations, but in scattered rural districts this is impossible, and the "endowment fund" it is proposed to raise will enable the Central Council to help such cases. We heartily commend the project to the women of Great Britain.

Sanitary Affairs Dominant.

We have often been struck at the great contrast in the treatment of sanitary affairs between the home and colonial and Indian papers. The contrast, perhaps, is most remarkable as regards the "big London dailies." The ordinary administrative routine of the metropolis receives but little notice in their pages. Of course, if there is anything like the housing question, out of which political capital can be made, notice is taken of it, and it is run for all it is worth —from the party point of view. If abstract theories on water supply, or sensational statements of the shortcomings of the water companies, are thought likely to influence a few votes, then these also are given prominence. But for a London daily to give three or four columns to a report of the proceedings of the London County Council or one of the metropolitan boroughs—why, such a thing is unknown. And yet the sanitary administration of the county is of more vital import to the inhabitants than the columns of simple nothings which go so largely to fill up the paper every day. Fancy the editor writing a leader on the proceedings of the Sanitary Authority! But in many of our Colonies this is just what does take place. The editors know full well that healthy conditions of life are the greatest problems before their readers, and every phase of administrative life is closely watched and duly commented upon. The effect of this cannot be over-estimated. Officers, Councillors, Aldermen, and all in authority, soon realise that their conduct of affairs is being closely watched, and only good can be the result. If the boroughs of London are ever to equal the provincial cities in enterprise and efficiency, the Press will have to take its share in bringing them up to the standard, and the great daily that is prepared to devote a considerable portion of its space to "bread-and-butter politics" will be the leader in the march of progress.

A Great Reservoir.

Last week a large company assembled at the invitation of the Southwark and Vauxhall Water Company to inspect the new works at Hampton and Sunbury, and to take part in cutting the first sod of an immense new reservoir at Walton-on-Thames. The Riverdale engine-house at Hampton was first visited, and great admiration was expressed at the three sets of magnificent expansion engines, which have recently been erected. Each engine is capable of pumping nine million gallons per day to a height of 280ft. They were designed by Mr. J. W. Restlar, the company's engineer, and made by the North-Eastern Marine Engineering Company. In striking contrast were the old Cornish engines, which are still doing duty. After inspecting the filter beds, the company went on to Walton, where a new storage reservoir is to be constructed by Messrs. John Aird and Co. When completed it will hold 1076 million gallons, and be one of the largest in the kingdom. The first sod was cut by the chairman of the company, Sir Henry Knight, who, at the subsequent luncheon, gave some interesting particulars of the company's operations. It supplies an area of forty square miles, with an estimated population of 837,207 in 124,770 houses. Last year the maximum quantity of water supplied on any day was 38 million gallons. To meet this demand there were filter beds sufficient to deal with 58½ million gallons, and pumping power capable of raising 78 million gallons per day. As to storage, the existing reservoirs were capable of holding 400 million gallons, and when the new reservoir was completed they would have no less than 1512 millions of unfiltered water and 71 millions of gallons of filtered water, making in all 1583 millions of gallons. Thus the company would have a storage sufficient for 56 days' supply without taking a drop of water from the Thames. Considering the magnitude of the works in hand by the other water companies, it was but natural that Sir Henry should "point a moral and adorn a tale." With the companies so fully alive to the needs of Londoners, why the necessity for the County Council to talk of spending millions in getting a water supply from Wales! Perhaps not, but if the County Council had never had its "tall

talk," there are many who think that the companies would have gone on in the old way and demonstrated their inability to realise that they had a duty to perform as well as "a dividend to pay." That something was needed is proved by the fact of Sir Henry Knight's own company quadrupling its storage capacity.

CORRESPONDENCE.

(*To the Editor of* The Sanitary Record.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

THE PLUMBERS' COMPANY AND THE REGISTRATION OF PLUMBERS.

Sir,—In reference to the correspondence on the above subject in your columns, can the Plumbers' Company, their solicitors, or anyone else, enlighten me as to the objects of the present registration movement?

At a recent meeting in Bury, if newspaper reports can be trusted, the following resolution was passed:—

"That this meeting approves of the present voluntary system of registration of plumbers *in the interest of the public health, and recommends that all plumbers' work in the district be done by registered plumbers.*"

The portion in italics is excellent on the face of it, but what guarantee has the public as to the efficiency of the registered plumber? That he earns the standard rate of wages of his district?

At the meeting at which the above resolution was passed, I understand that the secretary mentioned that under the old registration movement at least 50 per cent. of the candidates failed in the examination entitling them to registration—presumably on account of inefficiency. These 50 per cent. are now to be registered because they are master plumbers, or because they earn the standard rate of wages, and are to carry out work in the interest (?) of the public health!

According to a report of the Bury meeting, the Chairman stated that "it was insisted upon that chemists should pass theoretical and practical examinations, and that they should be in every way competent, but when it came to the plumber, who had the lives of all of them in his hands . . . they did not take the slightest notice . . . ." What would the chairman and a great many other people say if the chemists' examinations were dropped, and any man considered qualified because his master chose to pay him the usual rate of salary?

Apparently, the Plumbers' Company has gone back to its original procedure of registering anybody and everybody—a practice which the Company itself condemned, and to remedy which it instituted the examinations now discarded.

Personally, I should say, either register men who can be guaranteed efficient and upon whom the public can place confidence, or do not "recommend that work be done by registered plumbers in the interests of the public health," which latter, under present circumstances, is, to say the least of it, a farce.—Yours truly,

Examinations.

The Public Health Committee of the London County Council has received a report from Dr. Hamer concerning the outbreaks of enteric fever last September in Southwark (where there were 100 cases), in Lambeth (where there were about fifty cases), and in Kensal Town (where there were about thirty cases). In Dr. Hamer's opinion there are grounds for the suspicion that in Southwark and Lambeth the disease resulted from the consumption of fried fish received from particular shops.

Sanitary Inspectors' Associations.

LONDON.

The Council of the Sanitary Inspectors' Association have pleasure in announcing that the summer meeting and congress usually held in the provinces will this year take place in London, and it is understood that the City Corporation have kindly placed exceptional facilities at the disposal of the Association. An early announcement will be made of the date and particulars of the arrangements.

An ordinary meeting of the members of the Sanitary Inspectors' Association was held on Saturday last at the Carpenters' Hall, London Wall, E.C. Mr. W. H. Grigg (Fulham), the chairman of the Council, presided, and those present included Messrs. W. W. West, I. Young, McNair, Nurcombe, Warwick, T. G. Dee, Jordan, Morley, Henley, S. C. Legg, Dawes, Pettit, Wilkinson, Nessfield, E. Tidman, C.E., the hon. secretary, &c.

Mr. J. S. Dunn, fomerly of Poplar, but now Sanitary Inspector in Bulawayo, South Africa, forwarded a paper on "Sanitation in South Africa," and this was read by Mr. O. C. Hills. The author remarked that although his paper was entitled "Sanitation in South Africa," after hearing it, he was afraid they would be of the unanimous opinion that South Africa generally is a country without sanitation. In many respects the colonists were pioneers, and were carrying civilisation far into the interior of the Dark Continent, but they could not yet claim to be pioneers in public health administration. Owing to the disturbed state of the country on account of the war, it had been impossible to obtain all the statistical information which was desirable, and he was forced, therefore, to confine himself to the two towns with which he was intimately acquainted, viz., Cape Town and Bulawayo. As the first named was the oldest town of any importance, and the last named the youngest, a comparison between the two would not be without interest. Extracts from the Blue-book on the health of the colony in 1899 would cause them to open their eyes with astonishment at the very primitive methods still in vogue in many colonial villages. Cape Town and its suburbs had a population of about 165,000, and was charmingly situated. Two distinct schemes of drainage were now approaching completion, one for sewage and the other for storm water. The separate system was necessary owing to the excessive rainfall during a few consecutive months of the year. The ventilation of the sewers was effected by cast iron pipes, carried up the houses from the sewer side of the interceptor. Seapoint, an adjoining suburb, had adopted the water-carriage system, and the only other towns which had done so were Durban (the most advanced town in South Africa), Pietermaritsburg, and Port Elizabeth. Cape Town's water supply was from springs on table mountains, and extensive reservoir accommodation had been provided and was being increased, so that there should be an abundance of water for flushing purposes in addition to that for domestic use. The water was of good quality. Scavenging was done departmentally, all garbage and dirt being collected daily. Although the sanitary condition of Cape Town was yearly improving it would be some time before it could be favourably compared with a town of similar size and importance at home. Roads and gutters require much attention; the subsoil was in places frightfully polluted with slop and kitchen water; much slum property existed, and as house rent was high overcrowding was prevalent. The Malay community were dirty in their habits, and their customs and religious practices required thought and tact to

enable them to be dealt with successfully. Bulawayo was 1360 miles inland and 4000ft. above sea level; it was the capital of Matabeleland; the township was just six years old. Practically no attempt had been made to construct proper roads. Bulawayo was the nucleus of a large and flourishing city. Its present population was about 4000, the town was laid out in geometrical lines, the avenues being at right angles to the streets; the former were 100ft. wide and the latter 125ft. There were 1450 building plots, averaging 140ft. by 100ft., and these had sanitary lanes at the back for rubbish and night-soil wagons to pass along and perform their various functions. A park separates the towns from the suburbs, and here the stands or building plots were 300ft. by 200ft. with roads back and front. The pail system was in vogue for the removal of night-soil, and the work was performed nightly—an advantage which no other South African town enjoyed to the author's knowledge. The work was carried out departmentally, clean disinfected buckets being provided twice a week. The night-soil was conveyed to the municipal depositing site about three miles from the town, emptied into trenches, which were then prepared for tree planting. Rubbish, slop water, and dead horses were removed by the Council, but the system did not work quite happily. Large and offensive accumulations were not an unknown factor. The removal of slop water was the burning question in Bulawayo, as it is in the majority of South African towns. The town only had surface drainage, and the usual way of disposing of slop water was by scattering it over the building plots. Thus the subsoil was being polluted wholesale, and the purity of the well water was endangered. There was the waterworks company, but, owing to the fluctuating quantity of the water available, its variable quality, and high tariff, the demands on the company were not great. Moreover, 350 wells had been sunk in the township, and their use would not be abandoned for trifling reasons. It was regrettable that more care was not exercised in selecting their positions and in their construction, so as to guard against pollution. There was every opportunity offered for the entry of surface water and foreign matters at the mouth of the wells, and contamination by percolation from closets, dustbins, stables, washing water, &c., was easily accomplished. The Council recognised the necessity of obtaining a wholesome and abundant supply, and the matter was receiving earnest attention. In the meantime all doubtful well waters are being carefully analysed. With the exception of typhoid fever there was remarkably little infectious disease. It was well that it was so, because an outbreak would find the town very unprepared. The lazaretto was unfurnished, dilapidated, and without means of disinfection. Notification was compulsory, but there the law as regards infectious disease practically ended. At present they were preparing for the importation of the bubonic plague. There was, fortunately, no slum property. The slaughter site was unsatisfactory in the extreme, and the bye-laws were very incomplete. These matters would probably be rectified in the dim future, and the Council was negotiating for a loan for general improvements. Mr. Dunn then gave a number of quotations from the reports of district surgeons in various parts of Cape Colony, showing the dreadfully insanitary condition of their districts and the supineness of the Authorities in making proper provision; and in concluding he quoted the leading article which appeared in THE SANITARY RECORD of 28th December last, showing the excellent opportunities for municipal engineers and health officers in South Africa when the war is over.

On the motion of Mr. WEST, a hearty vote of thanks was accorded to Mr. Dunn for his paper, and to Mr. Hills for its delivery, and in the course of the brief discussion which followed, the hope was expressed that the facts related by Mr. Dunn as to the insanitary condition of many South African towns would be brought to the notice of the various Governments concerned.

Mr. HILLS acknowledged the compliment.

Mr. WARWICK (West Ham) then opened a discussion with an address showing the difficulties connected with the protection of food supplies in many towns and boroughs, and further consideration of the matter was postponed.

The usual vote of thanks to the chairman closed the proceedings.

NATIONAL UNION.

THE quarterly meeting of the members of the National Union of Sanitary Inspectors was held at the Shirehall, Stafford. Mr. W. Bland, of Urmston, presided.

Messrs. J. Arthur Jones, Wrexham; J. T. Lord, Bolton; E. J. Elcock, Sheffield; and W. V. Macdonald, Frimley, Surrey, were elected members of the Union.

The HON. SECRETARY (Mr. Spears) said that one of the Bills dealing with the superannuation of public officers would come before Parliament on May 9th, and as far as possible members were requested to place themselves in communication with the local members of Parliament with the view of securing their vote for the measure.

On the motion of Mr. WORRALL, seconded by Mr. EVANS, it was decided to petition Parliament in favour of the Public Officers' Superannuation Bill.

In answer to a question, the CHAIRMAN said the Council of the Union had instructions to take action with regard to the other Superannuation Bill which was also before Parliament.

The motion was carried.

The quarterly meeting of the Midland Centre of the Union was held subsequently, Mr. W. H. Coney, of Wednesbury, presiding.

It was decided to hold the next meeting at Tamworth.

Mr. F. T. POULSON, of Stafford, read a paper, in the course of which he said he had been asked to say something about the projected union of the National Association with that of the Incorporated Association, and with the further view of the inclusion of all other outstanding associations and members so as to form all Sanitary Inspectors into one united body. The time appeared ripe for this, and he thought that as the first steps had been taken, the union of the two first-named associations would probably soon be accomplished. At a meeting of representatives of the two associations at Liverpool, on April 13th, the following points were raised as a basis of general agreement before the union could take place:—(1) That all unattached members of the associations should be allocated to district branches; and (2) that branches should elect their own representatives on the Executive. When they were branches of the Incorporated Association the difficulty was in obtaining adequate consideration of the work and position of the provincial inspectorate, the chief factor being the overwhelming voting power of the metropolitan members. This preponderating influence made itself very obnoxious at times, and actions were taken, of which the provincial inspectorate generally did not approve. However, many of the old difficulties had been removed, and whilst they were ready and willing to continue on a satisfactory and equitable basis they recollected that they belonged to an Association which had proved that the ideas and reforms they asked for were workable, for they had worked on the lines laid down, and found that their Association had never looked back. However, while there were many advantages in unity, they were not going to sell their birthright for a mess of pottage.

One of the principal advantages of the union would undoubtedly be the taking of the necessary steps to

obtain the settlement of the question of superannuation. There was no doubt that they ought to be in the same position as poor-law officials. There was one feature of all appointments, such as those of Sanitary Inspectors, which should particularly weigh with the powers that be, and that was the mutability of the *personnel* of the appointing Councils. It was easy to imagine an officer devoting his best days to the service of an Authority and giving every satisfaction, yet in course of time, and owing to changes which succeeding elections produced, a Council was elected who "knew not Joseph," and who might think a younger man preferable. The appointment might be advertised, and the officer might not get elected, and consequently be placed in an awkward and humiliating position. This was a strong plea for security of tenure as well as for superannuation. The dressing up of Inspectors in uniform, which might be a cross between that of a railway porter and the advertising uniform of well-known soap or tea firms, was not calculated to enhance their self-respect. It was said to be necessary to keep the officers in order, and so that they might be easily noticed and spoken to in connection with sanitation, but it also caused much extra trouble and annoyance to the public. A uniform acted badly when places of business had to be visited in connection with infectious diseases, calling public attention to the fact, and possibly injuring the tradesman. He was inclined to think that men should have the confidence of their superior officers and be trusted, and they would be more likely to live up to that trust, and when they felt that they were recognised as effective units in the sanitary army they were at once put on a higher mental and social plane to that which they stood as mere uniformed numerals. There was as much need for a revision of the methods of training men for warfare in the sanitary army as had been proved to be the case in the fighting army in the South African campaign, and the Inspectors as the rank and file must keep themselves ready to act at any moment, in whatever capacity or duty they might be called upon in the face of some attacking force, as plague or epidemic, carrying out the ideas of the Medical Officers and the instructions of the Authorities fearlessly and well, so that they might feel that they had tried to do their duty.

The CHAIRMAN said the paper was an interesting one. There was no question on which they were more in favour of than that of amalgamation, and he hoped they would be banded together in one strong body, and thus enabled to obtain that to which they considered they were entitled—fixity of tenure and superannuation. He moved a vote of thanks to Mr. Poulson for his paper.

Mr. BLAND seconded the motion; and Mr. LOWRY and Mr. SPEARS continued the discussion in regard to the proposed amalgamation and superannuation.

The motion was carried, and Mr. POULSON briefly replied.

This was the whole of the business. The members afterwards had tea at the Dolphin Hotel.

SOUTH WALES AND MONMOUTHSHIRE.

THE first meeting of the session was held at Abersychan, Mon., on April 27th. There was an excellent attendance of members.

The Council met at 12.30 p.m. under the presidency of Mr. John T. Owen, Chief Inspector, Merthyr, vice-chairman of the Council.

The secretary read the correspondence between himself and Mr. John Terry, Bury, Lancs, in the matter of Unity, and after a careful discussion Mr. J. Preece James, Tenby, chairman of the Council, and Mr. J. Towy Thomas, hon. secretary, were elected as representatives to attend conferences to further this aim. In case of their failure to attend Messrs. J. T. Owen and Jas. P. Jones, Gelligaer, vice-chairman, to take their place.

At 1.30 p.m. the members and visitors sat to an admirably served luncheon at the White Hart Hotel, generously provided by the members of the Abersychan Urban District Council. Mr. W. B. Mitchell, J.P., presided, and was supported by Mr. A. A. Williams, J.P., Panteg; Dr. Herbert Jones, M.O.H., Hereford (late Rhondda); Dr. Mulligan, M.O.H., Abersychan; Councillors J. Daniel Jones, W. Barrett, A. H. Bailey, Jno. Morgan, members of the Abersychan Urban District Council; Mr. W. Lloyd Marks, hon. treasurer; Mr. J. Towy Thomas, hon. secretary; and representatives from Newport, Cardiff, Rhondda, Blaenavon, Rhymney, Panteg, Llantarnam, Pontypridd, Pontypool, Caerphilly, Gelligaer, Aberdare, &c. &c.

Mr. W. R. JAMES, Chief Sanitary Inspector, Abersychan, read an admirable paper on "Needed Reforms in Sanitary Administration from an Inspector's Point of View," for which he was enthusiastically thanked. Discussion upon the same was deferred until the next meeting.

The SECRETARY reported upon the action taken in reference to the Superannuation and Tenure of Office Bill, and that encouraging letters had been received from Col. Morgan, M.P., South Monmouth; Mr. R. McKenna, M.P., North Monmouth; Mr. J. Lloyd Morgan, M.P., West Carmarthen; Mr. S. T. Evans, M.P., Mid Glamorgan, promising to give the Bill their best attention.

The secretary was thanked for the immediate action he had taken in the matter.

The usual vote of thanks terminated a unique meeting in the annals of the Association.

The arrangements by Mr. W. R. James were perfect, and the people of Abersychan may well be proud of their able and deservedly popular Sanitary Inspector.

Public Works.

SEWERAGE.

THE Local Government Board has sanctioned the borrowing by the Brighton Town Council of £8400 for works of sewerage.

THE Newhaven Urban District Council intends to apply for a 5 per cent. increase to the sewerage loan of £884 in respect of contingencies.

A SCHEME for dealing with the whole of the sewage of the town and county asylum of Sleaford has been discussed by the District Council, but no action was ordered.

THE Local Government Board has given formal permission to the Bideford District Council to borrow £2500 for carrying out the East-the-Water drainage scheme.

SANCTION has been received to the borrowing of £13,000 for purposes of sewerage and sewage disposal at Pembury, Tonbridge. The question of a water supply for Brenchley is under consideration.

THE Local Government Board has sanctioned a loan of £3900 for the Ongar sewerage scheme. The Board apportioned the cost on the basis of population; High Ongar would contribute £1029, and Chipping Ongar £2571.

THE Bill, confirming a Provisional Order made by the Local Government Board, empowering the Urban Sanitary Authority of the Borough of Leicester to compulsorily acquire land for the disposal of sewage, passed the Chairman of Ways and Means last week, and was sent for third reading in the House of Commons.

A Local Government Board inquiry has been held by Colonel J. T. Marsh, R.E., at Sherrington, as to the application for a loan for works of main sewerage and sewage disposal, per plans by Messrs. D. Balfour and Son. of London and Newcastle. The scheme comprises the laying of 3½ miles of main sewers, with manholes and flushing arrangements, also the construction of bacteria tanks and the laying out of the land, the effluent from which will discharge into the river Ouse.

Col. J. T. Marsh, R.E., on behalf of the Local Government Board, held an inquiry at Hallaton last week as to the application by the Rural District Council to borrow £2000 for the purposes of sewerage and sewage disposal. It is proposed to acquire six acres of land for irrigation purposes. There was some opposition to the scheme from a minority of those present on the ground of expense, a less costly scheme being advocated. Evidence having been taken, the Inspector was shown over the ground.

Extraordinary difficulties are still being experienced in connection with Fulshaw sewerage works, Wilmslow. Further steps have just been taken to protect houses in one district, where a sewer has been laid at a great depth. The sewer here has been open for months, and has caused considerable trouble. House property has had to come down, and a heavy claim sent in to the Council. It is feared that other claims will be heard of. The scheme is likely to be a most expensive one, and is causing great uneasiness.

The plans and estimates prepared by Mr. S. I. Adams for the extension of the Chadwell St. Mary and Little Thurrock sewer have been again considered by the Ossett District Council. The Clerk said Chadwell Parish Council did not want the work carried out; they thought it was unfair to the ratepayers. The letter was referred back to the Committee to report upon. The plans and estimates prepared by Mr. R. T. Stewart for the extension of the Little Thurrock sewer to the northern portion of the parish were adopted; and it was resolved to apply to the Local Government Board for sanction to borrow £2750 to carry out the work.

A quarterly meeting of the Lincoln Town Council was held last Monday. Formal sanction from the Local Government Board having been received to the proposed loan of £50,000 for the purposes of sewerage and sewage disposal, the Health Committee recommends that the Finance Committee be asked to take steps to obtain the said loan. It also recommends that Mr. Everard be empowered to proceed with his scheme as modified, including the preparation of quantities, and inviting tenders for the work in such manner as he shall think fit. The Finance Committee has resolved that the Council request the Town Clerk to communicate with the Public Works Loan Commissioners and with three or four mortgage brokers inviting tenders as to the terms upon which the sum of £50,000 can be borrowed for a term of thirty years.

At a meeting of the Skipton Urban District Council, last week, a communication was read from the West Riding Rivers Board complaining of the discharge of insufficiently-purified sewage into the river Aire from the Council's sewage farm, and pressing for effective measures to be adopted forthwith. The Board, further, gave the Council notice that if by the 1st of July next they were unable to show that some steps had been taken in the matter the Rivers Board would have to exercise their further powers. The Chairman (Mr. J. B. Dewshurst) said that to tell them (the Council) that they had done so little was more than the Rivers Board had any right to say. The Skipton Council was the first to do anything in the nature of sewage purification worthy of the name so far as the vicinity of the Aire was concerned. The letter was referred to the Farm Committee.

Mr. W. O. E. Meade-King, M.I.C.E., one of the Local Government Board Inspectors, held an inquiry last week at Colchester regarding an application by the Town Council for sanction to borrow £19,000 for sewerage works and sewage disposal.

The Market Drayton Rural District Council has accepted Mr. T. Healey's tender of £1065 for the construction of the filter for the Little Drayton sewerage scheme. This brings the total cost of the scheme up to about £3600, and the Clerk stated that it would be necessary to apply for power to borrow £710 in addition to the amount sanctioned by the Local Government Board.

The Local Government Board has written the Grays Urban District Council stating that, after considering the report of its Inspector on the application for sanction to borrow £1500 for sewage disposal works, it did not think sufficient reason had been shown for abandoning the scheme of chemical precipitation and artificial filtration, and therefore it could not sanction the proposed loan. The Surveyor said the fact was the Local Government Board would not let them save £100 a year, but wanted to make them expend more money.

The Town Clerk of Bridlington has received notification of the consent of the Local Government Board to borrow £5960 for the purposes of main drainage. The scheme of drainage has been prepared by Mr. E. R. Matthews, C.E., and has been passed without amendment by the department. The work will be proceeded with at the close of the season. It was anticipated that some difficulty would arise owing to the railway company objecting to allow the drain to pass under the railway crossing unless £10 were paid to the company, but apparently the fears of several of the Councillors have proved to have been groundless.

Major-General H. D. Crozier held a Local Government Board inquiry at the Town Hall, Wolverhampton, recently into the application of the Wolverhampton Corporation for a renewal of the certificate granted in May, 1899, sanctioning the means used by the Corporation for rendering harmless the effluent from their sewage works and land flowing into Pendeford Brook and its tributaries. At the conclusion of the inquiry the Commissioner said the fact that nobody opposed the application was most satisfactory. He congratulated the Sewerage Committee on the success which had attended its efforts.

Mr. James Murray, C.E., Master of Works, and County Sanitary Inspector for Paisley, in the course of his tenth annual report for the Second or Lower District of the county, deals at some length with the water supply and drainage. The reservoir on the Brueacre Burn, Inverkip, capable of impounding about two million gallons, will he expects be entirely finished by the month of May. The high-level filters and clean water tank at Kilmalcolm have now been completed at a cost of about £2500. Bishopton drainage scheme has been completed at a cost of £1800. The features of importance in connection with the scheme are that the sewage is purified by bacterial treatment, the sewers are ventilated not by street gratings but by ventilating shafts at the end of the sewers, and at the extreme end of the village a flushing tank has been provided. At Kilmalcolm the Committee is negotiating for ground for the purification works, estimated to cost £4500. Mr. Copland, C.E., reported on the drainage of Lochwinnoch, estimating the cost of drainage and purification works at £3000, which would be equal to an assessment of 9d. per £. Owing to some little difference arising with the proprietor of the ground in which the purification works are to be constructed, the Committee deemed it expedient not to go further meantime. This is to be much regretted, as it will retard the progress of the work.

WATER.

The Water Bill promoted by the Kettering Urban District Council to secure an additional water supply for the town was before a Committee of the House of Commons last week.

The balance sheet presented to the special meeting of the Bolton Corporation Waterworks Committee showed a profit on the year's working of £14,543 6s. 4d., £14,000 of which it was decided should be transferred to the borough fund for the relief of the rates.

The Ripon Rural District Council has decided to support the action of the West Riding Rivers Board in their application to Parliament for power to look after the compensation water gauges of the Leeds, Harrogate, and Ripon Corporations in the water schemes they are now undertaking, the chairman being deputed to give evidence before the Parliamentary Committee.

The Local Government Bill for confirming the Buxton Urban Council Provisional Order, which seeks to empower the Buxton Council to increase its borrowing power for the purpose of the water undertaking by £15,000—making the total borrowing power £45,000—last week came before Mr. J. W. Lowther's Committee as an unopposed measure. Formal evidence in proof of the preamble was given, after which the Bill was ordered to be reported for third reading to the House of Commons.

Considerable complaint has recently been made concerning the water supply to the Ben Rhydding portion of the Ilkley urban district, and at the meeting of the Ilkley Urban District Council last week it was reported that samples of the water had been submitted to the examination of analysts, who had pronounced the water free from sewage or other objectionable contamination, and, in their opinion, suitable in every respect for drinking purposes. These reports were considered highly satisfactory.

The Louth Waterworks Company has, we understand, lost its opportunity. The Corporation was anxious to imitate the example of the Spalding Urban Council, and to acquire the right of water supply for the town. It offered the Waterworks Company £14,000 for their undertaking, but this was declined. A largely attended town meeting has unanimously determined that no further steps should be taken. The Waterworks Company will therefore have to continue its existence and its work, and also its risks, for property of this kind in a declining borough is not likely to increase in value.

Since the defeat in the Committee-room of the House of Commons of the Derwent Valley Water Board efforts have been and are being made, says the Leicester correspondent of a Sheffield paper, to overcome the difficulty with reference to obtaining stone. The delay necessitated by the throwing out of part of the Bill has led to some bitterness of feeling in view of the urgency with which water was required in ample quantity by Leicester, and the members representing that town have had thrown upon them a heavy responsibility, inasmuch as with dry summers, pending the construction of the works, Leicester will be in great danger of another water famine. It is stated that these very grave responsibilities will probably have a determining influence over the course to be finally adopted. Leicester cannot afford, in view of their very heavy financial responsibility, under the Derwent Valley plan, to enter upon another scheme of water supply. The enforcement of these considerations has had much to do with the course which is now being pursued, of making a thorough and systematic investigation of the whole of the district, with the view of ascertaining what other stone is available of a suitable character for the work required, and it is expected that in a short time a report of the result of the inquiries will be laid before the Board.

At the annual meeting of the Howden Rural District Council a discussion ensued in regard to the water supply question in Howdenshire. The chairman then informed the Council that he had seen Mr. Bickersteth, clerk to the East Riding County Council, which body had passed a resolution empowering the Sanitary Committee to employ an expert to the amount of £200 to deal with the best way of supplying the Howdenshire district with water. No further action was taken in the matter.

There has been a complete failure to agree on the part of the Urban District Council of New Mills and the Rural District Council of Hayfield, with the promoters of the Stockport Corporation Water Bill, which seeks to impound all the waters of Kinder, from which district both the Derbyshire Authorities have water schemes prepared. At the recent conference in London of all the parties concerned the promoters of the Bill insisted on a price per thousand gallons which the Derbyshire Authorities considered very excessive, and as a consequence the opposition will be proceeded with before the House of Commons Committee.

The water question must be immediately faced in Ross. Owing to the pressure brought upon them by the Urban Council, most of the landlords are now fitting up their tenants' houses with water-closets. The Town Clerk informed a recent meeting that he had received a number of applications for water for flushing purposes, and that the meeting should seriously consider whether they were in a position to grant the application. He said that if they made many connections for flushing purposes there would be a very serious depletion in the summer months for drinking purposes. He said that nothing could operate more strongly in favour of providing a water supply than the giving of much water for sanitary uses.

At a special meeting of the Wellington Urban Council held recently, the agreement respecting the proposed transfer of the Council's right to supply Hadley and Ketley with water to the East Shropshire Water Company was considered. The Council was given to understand that in drawing up the agreement the present consumers at Ketley (customers of the Council) had had their interests safeguarded, and the company would not have the power to charge them at a higher rate than the Council did at present. With regard to Hadley, which is not supplied at present, the Council considered it was not justified in undertaking a scheme to convey water to that neighbourhood on account of the cost, and the refusal of the large companies there to negotiate as to the terms on which water should be supplied them from the mains until they were actually laid. The East Shropshire Water Company, it was furthermore believed, could supply these localities more expeditiously than the County Council by the scheme they have under consideration. Ultimately the Council's seal was affixed to the agreement.

LIGHTING.

In the House of Lords the Honley Urban District Council Gas Bill has been read a second time.

The Local Government Board has sanctioned the borrowing by the Brighton Town Council of £6400 for fifteen years for electric lighting.

At a recent meeting of the Wigan Town Council the chairman of the Gas Committee stated that the net profit of the gas undertaking for the past year amounted to £11,000.

The Limerick Town Council has received sanction to the borrowing of £22,000 for the purpose of carrying out the scheme for providing electric light for Limerick. The loan will be issued in four instalments, and is repayable in twenty-five years.

At a meeting of Dumfries Town Council last week, there was submitted a favourable report by Mr. Ritchie, Edinburgh, on a proposal to establish a station for generating electricity by water power on the Cargen Burn, about two and a-half miles above the town. Consideration was deferred.

Petitions on behalf of the following in favour of the Derbyshire and Nottinghamshire Electric Power Bill have been deposited in the Private Bill Office of the House of Commons:—(1) Digby Colliery Company, (2) Warsop Urban District Council, (3) Blackwell Rural District Council, and (4) Skegby Rural District Council.

The Alfreton Gas Bill, which has already passed through the House of Lords, came last week before the Examiners of the House of Commons for proof of compliance with the further Standing Orders. There was no opposition at this stage, and the necessary formal proofs having been given, the Examiners decided that the further Orders had been duly complied with. The Bill will accordingly, in the usual course, be reported for second reading.

The Colwyn Bay and Colwyn Urban District Gas Bill, which has already passed through the House of Commons, came last week before the Examiners of the House of Lords for proof of compliance with further Standing Orders. There was no opposition at this stage, and the necessary formal proofs having been given, the Examiners decided that the further Orders had been duly complied with. The Bill will accordingly, in the usual course, be reported for second reading.

Tollington Park has developed a desire for electric light, and the statutory number of private consumers have banded themselves together and planted a requisition for the supply of the electric energy ground out at Eden-grove by the Lighting Committee of the Borough Council. The mains will cost £3500 to lay down. But the Council has no option but to comply with the requisition. New Court Chapel is going to be switched on, and it is also said that St. Mark's Church will adopt electric light, as well as a number of the well-to-do private residents.

The Otley Gas Bill, the main purpose of which is to convert the Otley Gas Company from a limited into a Parliamentary concern, having been submitted to the Local Government Board, was approved by that department conditionally on a few alterations being made. These did not affect the purpose of the measure, and were acceded to by the promoters, who recently appeared before the Chairman of Committees of the House of Lords (Earl Morley) to ask that the Bill might be advanced. Messrs. Sherwood and Co., Parliamentary agents, appeared for the promoters, and called Mr. F. T. Hunter, solicitor, of Bradford, to show that locally statutory requirements, &c., has been attended to. His Lordship ordered the Bill to be reported, with amendments, for third reading.

The new Swindon Gas Bill came before Lord Morley in Parliament as an unopposed measure last week. Its object is to confer further powers on the New Swindon Gas Company, to enable it to consolidate the existing ordinary capital and convert it into new stock with a uniform dividend of 5 per cent. Owing to the rapidly increasing demand for gas in the company's limits of supply, power is also taken to raise additional capital, which shall be sufficient to produce, including the premiums, £60,000. This new stock is to be offered by auction or tender before being sold to existing shareholders. Power to borrow on mortgage to the extent of £15,000 is also taken under the Bill. The directors are also empowered to declare interim dividends. Mr. W. H. Ludgate, chairman of the company, proved the preamble, and the Bill was ordered to be reported to the House for third reading.

The Enfield Gas Company are inviting, by advertisement, tenders for a new issue of £5000 Consolidated Stock, particulars of which may be obtained at their offices. In view of the great and growing increase of the company's business, and the very successful operations of last year in particular, notwithstanding the great rise in coal, this proposal will doubtless attract the notice of investors.

Last week the Select Committee of the House of Commons, of which Colonel Welby is chairman, further considered the Bill under which power is sought to incorporate a company to supply Mond gas to an area of about 135 miles in South Staffordshire. The case for the promoters having been concluded, evidence was called on behalf of the Birmingham Corporation, in regard to a portion of whose district of gas supply the new company seek powers. Mr. Orford Smith, Town Clerk of Birmingham, said the Corporation viewed the proposal of the Bill as being essentially an experiment, and, having purchased the statutory right to supply coal gas, thought it very hard that this competing scheme should be established until it had been proved Mond gas could be distributed satisfactorily and was suitable for manufacturing purposes. Mr. Corbet Woodall, a gas engineer of wide experience, said he did not think the advantages of the scheme were such to justify its application in a large area. For an undertaking which was admittedly experimental the scale was greater than was necessary; the object was to establish directly or indirectly a monopoly. The capital expenditure proposed would be too small, especially as regarded the distribution plant. Mains worth £650,000 rather than £361,000 suggested would be needed; and although the promoters made no provision for storage, he held that large gasholders would be necessary. Further, these should be regulated as to pressure, constant supply, and composition of the gas. The Committee adjourned.

GENERAL.

The Swansea Town Council has resolved to spend £425 in providing sanitary conveniences on the sands and at Treboeth.

The London County Council has agreed to lend the Battersea Borough Council £3230 for the provision of a disinfecting station.

Dr. Wheaton, Local Government Inspector, held an inquiry at Repton into the proposal of Repton District Council to borrow £6000 for isolation hospital.

An inquiry has been held into the application of the Clacton Urban District Council to borrow £21,000 for the laying out of the East Cliffs, and the construction of a shelter, hall, and other conveniences.

At a recent meeting of the Ilford Urban District Council a letter was read from the Local Government Board enclosing its formal sanction to the Council's application to borrow £9445 for alterations to the isolation hospital.

The Local Government Board has issued a circular of measures to be taken to prevent the introduction of plague. On the arrival of a vessel on which there has been any plague all rats on board should be destroyed. Rats, when destroyed on shipboard, should not be handled, but at once cremated.

At a committee meeting of the Coal Smoke Abatement Society, held at 14, Buckingham Gate on Wednesday, May 1st, 83 smoke nuisances were reported by the society's Inspector. Instructions were given that the reports should be forwarded to the Borough Councils of Hammersmith, Chiswick, Fulham, Barnes, Kensington, Acton, Shoreditch, Holborn, Willesden, Brentford, Port of London, Battersea, City of Westminster, in whose districts the nuisances occurred.

The Health Committee of the York City Council has rejected a scheme to supply sterilised milk and feeding bottles similar to that in vogue in St. Helens.

The Merchant Taylors' Company have voted 100 guineas in aid of the re-building fund of the Royal Hospital for Children and Women, Waterloo Bridge-road, in memory of Queen Victoria, and the Clothworkers' Company £100 for its maintenance.

With the close of the first half of 1901 the London County Council will be in a position to give notice to the South London Tramways Company of intention to purchase the 4¾ miles of lines in York-road, North-street, St. John's-hill, Lavender-hill, Wandsworth-road, Falcon-road, Queen's-road, and Victoria-road.

Major Tulloch held an inquiry at Darlaston recently on behalf of the Local Government Board with reference to applications by the District Council for permission to borrow £1400 for the extension of pleasure grounds, £335 for a steam fire-engine, and £200 for electrically equipping and wiring the Town Hall buildings.

The small-pox epidemic, which was revived in Dundee by the Maxwelltown outbreak, is spreading with alarming rapidity in that district, and last week three new cases were admitted to the hospital. The first patient—a woman 20 years of age—was removed from a dwelling in James-street, immediately over the house in which the woman from Govan lodged, and in which the outbreak originated. In connection with this case seven contacts have been removed to the reception-house. There are now nine persons in the hospital, and twenty contacts in the reception-house.

Notices have been issued by the Eccles Corporation to the owners of property and tenants of the houses on the alleged insanitary area of Eccles, bounded by Church-street, James-street, and Barton-lane, that it is the intention of the Council to present to the Local Government Board a petition, in pursuance of the Housing of the Working Classes Act, 1890, praying that an order may be made confirming an improvement scheme, whereby it is proposed to take compulsorily the lands described in the schedule attached to the scheme. A map of the area has been prepared by Mr. Picton, the Borough Engineer.

At the first meeting of the newly-constituted Darlington Rural District Council, a letter was read from the Local Government Board complaining that it had not received the Medical Officer's report, and intimating that the grant-in-aid would be forfeited if the report were withheld. The Clerk reported that he had received the report from the officer, but without any explanation. It was reported by the Surveyor that there had been a case of typhoid fever in the district. It was remarked that the Surveyor was in this matter supplying the place of the Medical Officer. A resolution was passed, on the motion of Mr. Elwon, seconded by Miss Scurfield, that the Medical Officer be asked to resign.

Three weeks ago the Local Government Board gave notice to the Dunfermline Town Council that if steps were not taken within a fortnight to have the colliery houses belonging to the burgh put into a sanitary condition, proceedings would be adopted under the Public Health Act. At a special meeting of the Council in committee last week, terms were adopted which had been agreed to by the West of Fife Coal Company, the lessees of the houses, under which the town will put in thorough repair and provide washing-houses, drainage, and sanitary conveniences for the whole of the houses included in the lease, with the exception of twenty-three houses which have been condemned, and the company will, during the remainder of the lease, pay to the town interest at the rate of 6 per cent. on the capital outlay, and be relieved of the proportion of rent for the twenty-three houses.

The Liverpool City Council has decided to entertain the Association of Cleansing Superintendents of Great Britain when they visit the city next month.

A Local Government Board inquiry has been held at Whitley into three applications by the Whitley and Monkseaton Urban District Council for sanction to borrow £1945 for improvements, £1587 for works of public street improvements and the formation of a new road, and £800 for the erection of public conveniences on the Whitley links.

A return has been issued showing, with reference to the cases of lead poisoning reported during the years 1899 and 1900, in the earthenware and china industry:—(*a*) The severity of the attack; (*b*) the number (if any) of previous attacks; and (*c*) the main symptoms referable to lead poisoning. There were eight fatal cases last year, as compared with sixteen in 1899.

The new baths which are being erected in Sommerton-road, Govan, are rapidly approaching completion, and one at least may be opened in the course of next month. Work on the baths was begun in August, 1899, and the whole will be finished well within contract time. There are two swimming baths, each 75ft. by 35ft., one 7ft. 6in. to 3ft. 6in. in depth, and the other 3ft. 6in. to 2ft. 6in. The smaller of the two will be open first. The deeper has a gallery providing accommodation for 400 to 500 spectators. The baths are provided with every approved appliance for heating and circulating the water, and there are besides a number of slipper baths for ladies and gentlemen. The entire buildings cover an area of 3940 yards, and the cost will be £25,000.

A Local Government Board inquiry has been held at Northwich relative to the decision of the four Mid-Cheshire Local Authorities to object to an order of the County Council constituting the Northwich, Winsford, and Middlewich urban districts into a united district for the provision and maintenance of an infectious diseases hospital. Mr. Algernon Fletcher opened the case for the Rural Council. He said their main objection to combination was that the Authority had been, was still, and would continue to be, desirous of making due provision for the wants of its own district. He contended that the Act was never intended to force combination upon an unwilling people. He urged that combination was impossible, inasmuch as there was no permanency in erections in the Northwich and Winsford areas. Mr. Colt Williams, for the County Council, argued that the County Council had been in no way coercive, and had given each Authority ample time to make proper provision. Taking each of the existing hospitals, the accommodation was altogether inadequate. Expert evidence was then given.

At its meeting on Tuesday the London County Council arranged for another issue of £2,000,000 London County Stock. It is interesting, says the *Westminster Gazette*, to note that the fixed-price principle which was adopted as an experiment at the time of the last issue, and proved so successful, is to be again put into force. In June last year the County Council offered £5,000,000 in three per cents. at 97½, and it may be remembered that there was such a rush for prospectuses that the supply at the Bank of England momentarily failed. The amount was applied for some five times over, and the quotation immediately rose to 1⅜ premium. The price at which the new issue will be made is awaited with lively expectation, the quotation for the existing issue being 99½, before the new issue was expected, although it has fallen to-day. That the applications will be large, despite the issue of Consols, on which the first instalment falls due at the end of next week, is almost certain, as the security is for all practical purposes as sound as Consols, and the yield even at par, is much better.

PERSONAL.

Dr. Boyd, of Southampton, has been appointed Medical Officer of Health for South Shields.

Mr. J. S. Hendey, of West Bromwich, has been appointed Borough Surveyor for Cannock Chase.

Mr. H. W. Smith has been appointed Resident Engineer for Leigh, at a salary of three guineas per week.

Mr. T. Latham, of St. Leonards-on-Sea, has been appointed Inspector of Weights and Measures for East Riding.

Mr. W. Parsons, of Leamington Spa, has been appointed Sanitary Inspector for Stroud, at a salary of £120 per annum.

The Local Government Board has sanctioned the appointment of Dr. James Eaton as Medical Officer of Health for Grantham.

Dr. C. Matthews has been appointed Medical Officer for the Atherington district of Barnstaple, in room of Dr. Anderson, resigned.

The Local Government Board has sanctioned the permanent appointment of Dr. A. B. Vise, as Medical Officer for the Holbeach South District.

Mr. J. E. Fothergill, of Arnold, Notts, has been appointed Surveyor and Inspector of Nuisances for the urban district of Brentwood at a salary of £150 per annum.

Messrs. G. F. Clark, of Southampton, and G. J. Gregory, of Portsmouth, have been appointed Sanitary Inspectors of Holborn borough, at salaries of £130 per annum.

Mr. T. F. Strutt, who for sixteen years was senior and Chief Sanitary Inspector to the late Strand Board of Works, has been appointed Chief Sanitary Inspector for the City of Westminster.

The Southwark Borough Council has received a letter from the Local Government Board sanctioning the payment to Mr. G. Millson, as Medical Officer of Health, of a salary at the rate of £750 per annum from November 28th, 1900.

Dr. George Turner has been appointed by Sir Alfred Milner Medical Officer of Health for the Transvaal. Dr. Turner, who prior to the outbreak of the war filled a similar position in Cape Colony, has been provisionally acting as Medical Officer for the Transvaal, and his services have been recognised by Lord Roberts.

Mr. Burnage, who has served his articles with Mr. Molineux, Superintendent Surveyor to the Ulverston Rural Council, and has been acting recently as temporary Surveyor for Low Furness, for which post he was an applicant, has been appointed Assistant Surveyor to the Warrington Rural Council, being selected out of sixty-six applicants.

Darlaston. — The annual report of Dr. Sydney Partridge, Medical Officer of Health for Darlaston, has been issued, and records a birth-rate of 38·19, and a death-rate of 24·24 per 1000 of the population. There were 193 deaths of children under five, and although this was 17 fewer than in the previous year the percentage was 5·92 of the total, the excessive mortality having been attributed chiefly to injudicious feeding and insanitary conditions. There had been about 88 cases of neuritis due to the presence of arsenic in beer, men being more frequently attacked than women. There had been no deaths from the disease, and no fresh cases had occurred since 1st December.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2186.—Water Containing Chlorides: Filter for, Required.—"Inspector" writes:—"A well about a mile from the seacoast yields a water containing an excess of salt. Is there any reliable filter that will reduce the excess of chloride?"

Answer.—There is no ordinary household or domestic filter to our knowledge which can be depended on to reverse the sodium chloride in the water.

2187. — Private Street, Making Up: Procedure.—"Surveyor" writes:—"About two years ago A opened a new street in the town of B, first obtaining the approval of the Rural District Council in whose area B was at the time. Recently B has been formed into an urban district. A undertook, when submitting his plans, to form the new street and cover it with 9in. of ballast, and 3in. of metalling. This metalling has not, however, been carried out, and some of the houses are now ready for occupation. *Query.*—Can the Urban District Council of B now refuse to grant certificates of occupation to the house owners until A properly metals the road? If not, how can A be compelled to do the work? I may say that the Urban Council is prepared to take over the street as soon as it is properly done."

Answer.—The Council cannot withhold certificates of occupation of houses on the grounds stated. The Urban Council may enforce the making up of the street, under Sec. 150 of the Public Health Act, 1875, and we advise that when the road has many houses built upon it that this procedure be followed. The Council are not enabled to take over the road until it has been sewered, levelled, paved, metalled, and made good to their satisfaction.

2188.—Connecting Drains into adjacent Authority's Sewers: Rate of Contribution.—"Surveyor" writes:—"Could you oblige me with information as to the amount charged to owners outside a drainage district wishing to connect to another Authority's sewers under Sec. 22 of the Public Health Act, 1875? Or what do you consider a fair basis to work on?"

Answer.—What appears to be a very general and reasonable payment is an annual payment at the rate of 6d or 8d. in the £ on the rateable value of the premises to be drained.

2189.—Child in Filthy Condition: Power of Medical Officer of Health.—"M. O. H." writes:—"A child attends an elementary school in this district, and the mistress finds her head in a filthy condition from vermin. She sends her home, and the matter was laid before the School Attendance Committee, who refer it to the Rural District Council as Sanitary Authority. They request me as Medical Officer of Health to inquire into the matter and report on it. Is this any part of my duty as Medical Officer of Health, and if so what can I do, and under what Act of Parliament?"

Answer.—The Medical Officer of Health can visit the house where the child resides, and if, as is probable, it is in a filthy condition, he may issue a certificate under Sec. 120 of the Act of 1875, or if the Infectious Diseases Prevention Act, 1890, is in force in the district, under Sec. 5 of that Act for the cleansing and disinfecting of the house. He may advise the parents or guardians as to the necessity for keeping the child in a cleanly condition, but there is no statutory power to compel such cleansing of the child.

2190.—Fish Unfit for Food: Condemnation when not Offered for Sale.—"G. H. P." writes:—"A, a London wholesale dealer, sells to B, a country retailer, a case of fish guaranteed to be good. B, upon his arrival in the country, opens the case, and finds the contents unsound, and unfit for food. He thereupon places the same in his cart and takes it to the local Inspector of Nuisances, who at once condemns the fish as unfit for food. It will be noted that B had not deposited the fish in any place for sale, had not prepared it for sale, nor did he, upon seeing its condition, intend it for the food of man, and it would appear that by applying to the local Inspector he does so simply to protect himself from loss and any liability. Will you kindly say (1) Who was responsible under Sec. 116 of the Act of 1875, A or B? (2) Is the act of seizure under the same section compulsory or optional? (3) What would be the correct action of the Inspector in this case?"

Answer.—(1) The vendor A if he sold, as it would appear was the case, the fish for human consumption, was the person liable. Unless the Local Authority have adopted Part III. of the Public Health Acts Amendment Act, 1890 (see Section 28

thereof) the Inspector was not obliged to act, as the fish was not intended, being in B's hands, for human food. (2) Seizure of diseased meat is optional, but an Inspector would probably deserve censure if he neglected to discharge his duty in such cases. (3) The action of the Inspector in seizing the meat was, subject to Answer 1, justifiable. It must be observed, however, that a justice must condemn the food. It is not the province of an Inspector.

2191. — Appointment of Sanitary Inspector: Is a Licensed Victualler Qualified?—"G. P." writes:—"I enclose cutting from newspaper relating to a Local Authority which had appointed a licensed victualler as Sanitary Inspector. The Local Government Board, however, informed the Authority that such a person could not hold the appointment. Will you please advise whether it is intended to mean that an Inspector must not keep a public house while holding office, or does it mean that he must not previous to appointment have been a licensed victualler? I wish to add that I find the 'Notes and Queries' column gives a great amount of useful information."

Answer.—The refusal of the Local Government Board to sanction the appointment of a licensed victualler to the office of Inspector of Nuisances in the case named may be taken to mean that no person who is a licensed victualler can carry on such a business and act at the same time as an Inspector of Nuisances. Any Local Authority who expects such a tradesman to be capable of discharging his duties impartially, and with a proper regard to the sanitary administration of the district, manifests an ignorance which is not creditable.

2192. — Factory Inspectorships' Examinations, &c. — "E. H. F." writes: "Will you kindly inform me if there is in existence any examination board which grants certificates for proficiency to act as Factory and Workshop Inspectors? Please also advise where all necessary information respecting the same and the appointment of Factory Inspectors may be obtained."

Answer.—The querist will find all information respecting the examinations and qualifications for Factory Inspectors in our replies to queries 994 and 1485 in our issues of March 18th, 1898, and May 26th, 1899, to which he should refer.

Death-rates in Urban Districts in 1900.—Dr. Cecil Moore, M.O.H., City of Hereford, writes:—"Referring to Query 2185 in your issue of the 2nd inst., your correspondent will find in the *British Medical Journal* for February 23rd, 1901, page 494, an article on "English Urban Mortality in 1900," which is specially reported, and will be found interesting."

Answer.—We are much obliged to Dr. Moore for the valued information. We may add that the mortality rates in thirty-two great provincial towns in the kingdom in 1900 was furnished in our reply to Query 2117 in our issue of March 14th. The birth-rate in these towns for 1900 was 29·9; death-rate, 20·0; and death-rate from the principal zymotic diseases, 2·69 per 1000 living.

PUBLIC LIGHTING BY GAS & ELECTRICITY

By W. J. Dibdin, F.I.C., F.C.S.,
Late Chemist and Superintending Gas Examiner to the Metropolitan Board of Works and the London County Council.

(*Continued from page* 264.)

CHAPTER XVIII.—DISTRIBUTION OF LIGHT.

The methods of distributing artificial light, whether for open spaces or for indoor illumination, must be very carefully considered. In too many instances a single powerful electric light or gas burner is placed in a position from whence its rays spread out in such a manner that the illumination obtained at the most distant point is considered sufficient for the purpose required. Such a system is, in principle, most wasteful, as in order to secure a sufficient degree of illumination of light at a few points, an enormous excess is wasted at the majority of the others, whilst the strain on the eyes of the individual whenever the direct rays from the powerful light source impinge upon them is most taxing.

The wonderful accommodating power of the diaphragm of the eye largely mitigates this evil, truly; but an evil it is, and one which is increasing. There can be no doubt whatever that the work of the professional oculist has been not a little enhanced by the ill-considered systems of artificial illumination so much in vogue during the past two or three generations. Many people now-a-days practically spend all their lives, especially during the winter months, working by artificial light. Every time the direct rays from a light source impinge directly upon the retina, the iris, or "pupil," of the eye instantly closes until the intensity of the rays passing through it is reduced to bearable limits. As soon as the direct rays cease to enter the eye, the pupil expands in order that sufficient light from the less illuminated object in view can act upon the optic nerve, as otherwise the object viewed would be invisible, or nearly so. This constant action of the pupil, or "guardian angel" of the eye as it might be termed, combined with that in the optic nerve, and the crystalline lens, becomes most fatiguing, and in time unquestionably affects the power of vision.

The dazzling effect, as it is commonly called, of intense light, is perhaps most noticeable in a street or country road on a dark night, when the ordinary gas flame has been replaced by an incandescent burner. As the observer approaches the light the illumination is clearly perceptible up to the point at which the lamp-post stands, but beyond that all is utter darkness, by reason of the contrast. If the observer's eyes are shielded from the direct rays, the illumination of the immediate background will at once be seen to be fairly good. It was this effect, enormously intensified, which made it necessary to enclose electric arc lamps in opal or ground glass globes. It is not necessary to dwell on the point further at present, but it is eminently desirable that it should be clearly indicated, with a view to ensuring its avoidance to the utmost extent possible.

The first object to be kept in mind when designing an installation is that the place to be illuminated should have as far as possible all parts equally brilliant, without undue shadowing in any part. For this reason powerful arc lights should be reserved for large interiors and open spaces. For small interiors the incandescent lights are at the present time most suitable. Many persons prefer the lights arranged round the room against the walls. It is, of course, largely a matter of taste; but, for the reasons above referred to, it is decidedly bad for the eyesight that the lighted source should be placed in a position from which the direct rays impinge upon the eyes. Apart from this by no means unimportant consideration, it is very much open to question whether it is always so effective as it is often claimed to be.

For instance, take the case of an ordinary sitting-room. In many instances pictures are hung upon the walls. What will be the effect on these when the light is held by a bracket on the wall about 12in. or 18in. in front or on one side of the picture? Again, if one decides to read comfortably, the reader's back should be turned towards the light. If this is on a small bracket the reader should sit facing, or near to, the middle of the room, a position not always desirable. The older method of having the lights in a sitting-room as near the ceiling as possible, and fairly distributed, is by far the best. If sufficient lighting power by this method cannot be obtained, then by all means use a small single light source as close as possible to the object to be illuminated. But this is not the general illumination which is the object under consideration.

The method of diffused top-lighting is well exemplified in the case of many of our public rooms, in which the incandescent lights are distributed all over the ceiling, with the result that they do not distress the eyesight of the observer, whilst a thoroughly uniform illumination is secured in all parts of the room.

The system adopted in certain halls, such as that arranged by Mr. Sugg at Reading, in which the lights are placed round the top of the walls behind glass screens, so that the direct rays are invisible, is excellent. Another instance of the same kind is that at the Houses of Parliament, in which the gas lights are placed over glass screens in the ceiling, with the result that a perfectly even illumination is maintained.

One objection raised to these methods is that the expense is greater than would be the case if the lights were visible. This raises a point of economy which, although desirable and necessary in many instances, does not, and should not, carry all before it. Where the comfort and convenience of large numbers of people are concerned for many hours at a time, undue economy in regard to effective illumination will often entail eventually such serious results in respect to eyesight that it often really becomes the worst form of extravagance.

The first point, therefore, which must be considered is, that the lighting arrangements must be thoroughly equal to the requirements of the case. This brings us to the consideration of the most desirable working power of light at the immediate point of observation.

Many years ago Mr. Sugg suggested that the standard of artificial illumination should be the degree of illumination afforded by one standard candle placed at one foot distance from the surface to be illuminated. Sir William Preece subsequently proposed at the Paris Electrical Congress in 1889, the "lux," by which term he indicated the illumination afforded by a Carcel lamp acting at a distance of one metre. As the Carcel lamp is equal to 9·5 English standard candles, and the metre is equal to 3·2809ft., and the illumination is inversely to the square of the distance, it follows that the quantity of light received upon a standard surface in the case of the lux would be practically the same as in the instance proposed by Mr. Sugg. Strictly, a candle-foot is 0·882 of a lux or Carcel-metre, and a lux is 1·133 candle-foot. We may, therefore, adopt the "candle-foot" degree of intensity as a useful guide. For the purpose of working out the required intensity of a series of lights for illuminating a given area, Mr. Sugg has compiled the table given on the next page.*

"*Illuminating effect* is the distance from the surface to be illuminated, at which the standard candle must be placed to give the same amount of light as that supplied by a given light at a given distance. This may be found by dividing the distance of the light by the square root of its intensity — see table. Thus a

* Abstracted from the "Gas Engineers' Pocket Almanac." W. Sugg and Co.

50-candle light at a distance of 15ft. would give an effect equal to that of one candle at a distance of 2·12ft., as $\frac{15}{7\cdot07} = 2\cdot12$.

"*Illuminating value* is the strength expressed in candles of the light which would be required at a foot distance to produce the effect of the given light at its given distance. This is found by dividing the intensity by the square of the distance." Thus it may be desired to ascertain the strength of the light which would be required at a foot distance from a given object to produce the effect of a sixteen candle lamp placed 6ft. from that object. The answer is $\frac{16}{6^2} = 0\cdot44$, which is the "candle-foot," or "illuminating value" of the light obtained under the conditions given.

Table of Square Roots for the Calculation of Illuminating Effect.

No.	Square root.	No.	Square root.
1	1·0000	17	4·1231
2	1·1442	18	4·2426
3	1·7320	19	4·3589
4	2·0000	20	4·4721
5	2·2360	25	5·0000
6	2·4492	30	5·4772
7	2·6457	35	5·9161
8	2·8284	40	6·3245
9	3·0000	45	6·7082
10	3·1623	50	7·0711
11	3·3166	100	10·0000
12	3·4641	200	14·1421
13	3·6055	300	17·3205
14	3·7416	400	20·0000
15	3·8730	500	22·3607
16	4·0000		

If it is required to ascertain the candle-power of a lamp which should be placed at a given distance from the object to be illuminated, in order that the degree of illumination shall be equal to that which would be afforded by one candle at a foot distance, any number in the above table may be read as *candle-power of the lamp required*, and its square-root as the *distance in feet at which the lamp is to be placed*. Thus, let it be required to illuminate an object to the extent of a "candle-foot" by means of a lamp which must be placed 9ft. distance: As $9^2 = 81$ = the illuminating power of the lamp required.

The origin of the expression "candle-foot" is related by Mr. Sugg to be as follows† :—"The only case in which he had been able to feel satisfied with lighting requirements was that of the Grand Committee-room of the House of Commons. A piece of paper was given to him with some pencil marks upon it, and his instructions were that a sufficient amount of light should be given to enable a man with ordinary eyes to read what was on the paper. He had only to get half a dozen men to read the paper, and see at what distance he held it from a standard candle. Then the problem was solved, the light required being one candle-foot."

In the opinion of Mr. Trotter the candle-foot is a very convenient and "comfortable" illumination. It is for most people the best illumination for reading, and is to be found on most well-lighted dining tables and billiard tables. More than 2 candle-feet is seldom attained in artificial illumination.

The importance of reflection in the distribution of light must not be overlooked, as by its judicious utilisation greatly enhanced results may be obtained, whilst in some cases the use of reflected light only has been found to give the most satisfactory results, where, for instance, operations of a delicate nature, such as fine wheelwork and other mechanician's work, have to be performed. Mr. G. Kapp has described‡ the following method of utilising only reflected rays in the case of a factory in Berlin, where great difficulty had been experienced in finding a suitable light. The ordinary arc lamp would not do because it cast too strong a shadow, and, in turning arbors and axles, and milling toothed wheels, a uniformly diffused light was required. Glow lamps, which might have fulfilled this condition, were too much exposed to breakages from chips flying about and carelessness of workmen. The solution which the manager of the shop found was to put arc-lights into big funnel-shaped covers, whitewashed inside, and to hang them up 8ft. from the floor. The ceilings were kept white-washed, and the effect of the lighting was excellent. The arc could not be seen, being entirely hidden by the funnels, but the room was filled with a very soft diffused light. Another similar instance is that quoted by Mr. G. F. Deacon, who referred to the public library in Liverpool, the Picton Reading-room, as one of the best illuminated rooms in the kingdom.

It was a circular room, 100ft. in diameter, with a domed ceiling. For the purpose of illuminating the tables and floors he put in the centre of the room three arc lights back to back. Under them he put an opal chalice 12ft. in diameter, resting on an ornamental vase. He then whitewashed the dome, and the effect was excellent. The absolute amount of light was nearly uniform over the whole surface of the tables.

The degree to which white surfaces reflect light is not generally so well understood as it should be. According to Mr. Trotter, good paper, plaster of Paris, and even whitewash, have a reflecting power equal to that of ordinary looking glass, viz., about 85 per cent.

It has been held that outdoor illumination commences to be useful only when it is comparable to moonlight.

The following determinations of the intensity of moonlight are on record, viz.:—

Authority.	Moonlight = 1 candle at feet distance.	
Plummer*	8·72	Average = 7·77
Dibdin†...	7·20	
Dibdin†...	6·33	
Dibdin†...	8·60	
Trotter,‡ average	8·00	

* "Monthly Notices," Roy. Ast. Soc., vol. xxxvi.
† "Proceedings," Roy. Soc., vol. li.
‡ Inst. C.E., see *ante*.

Taking this average of one candle at 7·77ft. distance, moonlight is therefore equal to 0·017, or, say, one-sixtieth of a foot-candle.

It will be understood that these determinations apply to full moon, but at different zenithal distances. The point in all its phases is a complex one, but the above general results will be sufficient for our present purposes.

The degree of illumination of certain public interiors may be gathered from the following tabulated results of observations by General Festing, Mr. A. P. Trotter, and others :—

NUISANCES AND METHODS OF INSPECTION.[1]

By J. Spottiswoode Cameron, M.B., B.Sc., M.O.H. Leeds.

NUISANCES AND INSANITARY CONDITIONS.

(*Continued from page* 401.)

The water-closet, if inside the house, is often placed on the landing between the flights of stairs. The pan itself must, of course, be looked at, and the joint of the trap felt over with the finger. Any smell about the apartment should have been noticed on entering. The woodwork must be examined for fungi, the riser removed, and the space behind scrutinised for leakage or accumulations. The flushing rim of the pan should also receive attention. I have found it foul with excrementitious matters in a perfectly clean house where the basin itself was carefully attended to.

The efficiency of the flush will be examined, and before the inspection of the house is completed it will probably be convenient to put a smell test down the pan. If this is done carefully, it is possible to arrange it so that the smell shall not be generated until the substance used is past the trap. If there be any leakage of the joints of the pan, the smell of the test will be quickly discovered in the closet itself. If there be a

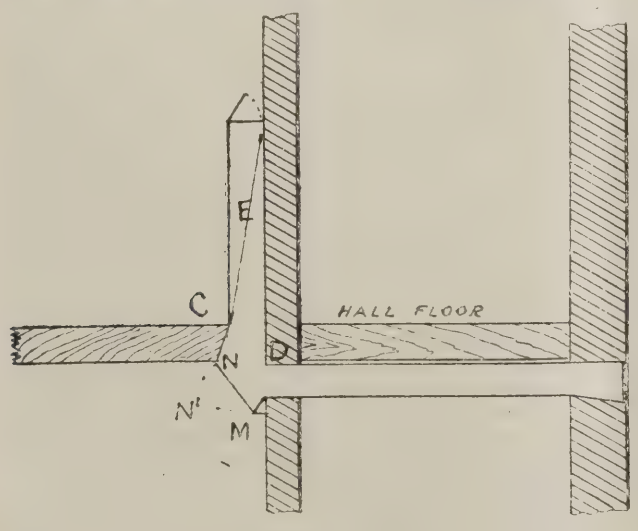

Fig. 9

leakage in the drains elsewhere in the dwelling, the smell may not be detected for perhaps as long a period as half an hour. It is convenient therefore to set the test going before completing the inspection. To the choice of strain tests I shall refer later.

The closet itself should, of course, be against the outer wall, should have a good large window—the ordinary water-closet window is ridiculously small—and this window should be made to open. There should also be some permanent means of ventilation, preferably at two points above and below, and if possible from different sides of the building. This can sometimes be obtained, as shown in the diagram, (Fig. 9), where the air is brought underneath the flooring of the passage. It is preferable, of course, to have a sort of ante-room leading to the closet, with its own window and its own ventilation. This is generally insisted upon in hospitals (Fig. 10).

I find a little difficulty in getting from our assistant inspectors the exact situation of the water-closet when it is inside the house. This, as you know, is fortunately an exception in cottage houses. The size of the soil-pipe is on the form already shown you, but I have found it desirable in the small number of cases where the closet is inside the house, to ask for further information in the form of answers to the following queries:—

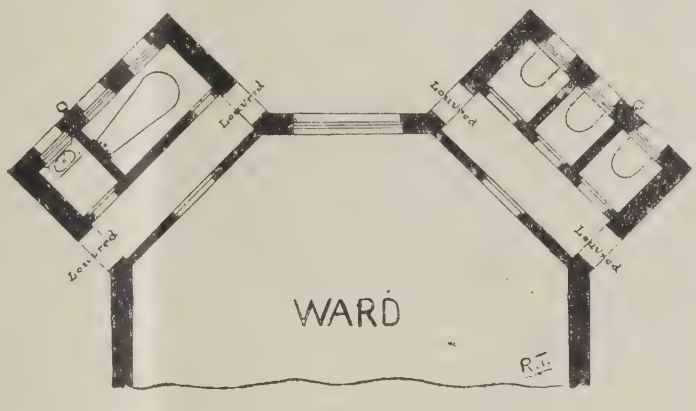

Fig. 10

Inside Water-closets.
(Special queries.)

The Inspector is required in filling in the information about houses containing inside water-closets to state in each case:

(*a*) Where the water-closet is situated:

(*b*) How the apartment is ventilated (size and position of ventilator):

(*c*) How it is lighted (size of window, nature of sash):—

(*d*) The relation of the door of the apartment to bedrooms, &c.:

(*e*) Whether the soil-pipe is entirely inside the house, or, if only partly, how much is inside:

(*f*) Where the joint between the basin and the soil-pipe is:

(*g*) What is the kind of basin:

(*h*) Whether there is a syphon flush:

(*i*) And to give any further information of a similar kind.

A

B

The pan of the water-closet should have as little wood-work around it as possible. A riser is a disadvantage. On the whole, probably the best kind of pan is the wash-down so shaped that the basin descends vertically behind, and that the water in the trap lies for a few inches in the basin. It is of the greatest importance in cottage houses that the whole contents of the closet cistern should be discharged without the necessity of holding back the valve. There are various syphon arrangements by which this can be effected. The extra cost to the owner is soon returned in the saving of stoppages.

The soil-pipe should go outside the house as quickly

[1] A lecture delivered in the Philosophical Hall, Leeds, April 13th, 1901. The illustrations to this lecture are from Dr. J. Spottiswoode Cameron's little work, entitled "Is my House Healthy?" published by Mr. R. Jackson, Leeds, and are reproduced in these columns by special permission

as possible, and should be continued its full bore above the roof of the house. It, of course, should not be used as a fall-pipe, as in the diagram (Fig. 12), still less should it open near a window (Fig. 13).

The disconnection of the bath and lavatory wastes should be, as shown in diagram (Fig. 5), managed in a similar way to that of the kitchen sink. It may be necessary to have a fall-pipe head, especially if roof water is to be carried down, as shown in the diagram

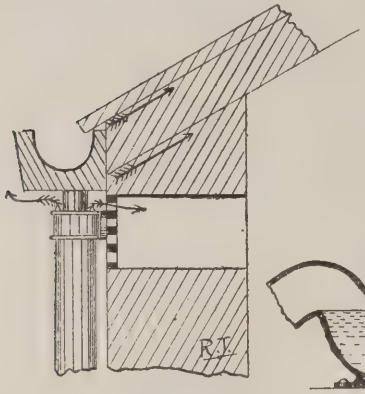

Fig. 12

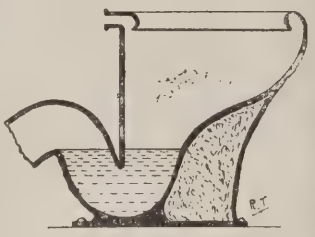

Fig. 11

A common fault consists in carrying a lead waste-pipe outside the house and into a larger iron fall-pipe reaching down to the ground. The fault consists in sealing the upper end of this iron portion of the waste, thereby making a dead end immediately outside the S trap. The larger pipe, fouled with suds, is never thoroughly ventilated. If the upper end is left open, protected if need be by wires, a current of air is sent down the pipe every time the basin is used.

Fig. 13

In glancing through the bedrooms it is well to look not only for evidence of damp, but to inquire, should the papers be of a particularly brilliant character, whether any of the family have suffered from sore eyes or symptoms of peripheral neuritis, and, if necessary, have a specimen of the wallpaper analysed for arsenic. The practice of putting the new over the top of the old paper is very unwholesome, and, if your visit is on account of illness, must be kept in mind.

(To be continued.)

ASSOCIATION OF CLEANSING SUPERINTENDENTS.

MEETING AT SHEFFIELD.

The quarterly meeting of the Association of Cleansing Superintendents of Great Britain was held in Sheffield, in which city the Association was inaugurated three years ago. Since that time it has made considerable progress, and is now a flourishing institution. The president is Mr. M'Taggart, of Bradford, and members attended representing Leeds, Leicester, Nottingham, Burton, Salford, Rochdale, Huddersfield, Buxton, Liverpool, Widnes, Withington, Stockport, Chesterfield, Burnley, Warrington, Ashton-under-Lyne, and other places.

Considerable interest was manifested by the visitors in a number of plans of the new destructor in course of erection at Penistone-road, which had been pinned up for their inspection in the Council Chamber. When all the company had arrived, the party, numbering 46 in all, left in conveyances for the Brightside baths. Councillor Chas. Hobson, Councillor Gent, and Councillor Nowill accompanied the visitors, whilst Mr. James Jackson, the Sheffield Cleansing Superintendent, acted as guide. The Brightside baths are the ones most recently erected by the Corporation, and are, consequently, quite up to date. Accompanied by Mr. George Hope, the manager, the visitors were shown round the fine swimming bath, which was generally admired, the slipper baths, and the basement where the washing is done and where the water is heated. The large cistern, it was explained, was capable, under forced pressure, of heating 3000 gallons of water per hour.

The conveyances next took the party to the Lumley-street destructor, this being the most interesting visit of the morning. Proceeding along the wide approach road, the party, conducted by Mr. Jackson and Mr. Arden (the engineer at the destructor), were first shown the tipping platform, which is 37½ft. wide, and runs the whole length of the building, 154ft. The cells were then inspected. The three large fans, each running at over 1000 revolutions per minute, were in motion, and these accelerating the pull of the chimney, a great draught of air was produced, and the burning powers of the cells appeared to be tremendous. The cells are sixteen in number, and are guaranteed by the builders, Messrs. Goddard, Massey, and Warner, Limited, of Nottingham, to burn ten tons of refuse each per twenty-four hours. This gives a total of 160 tons per day for the whole destructor, or something near a third of the total refuse of the city. The cells are 6ft. by 6ft. square, the arches all turned with headers throughout, and the fire-bars are of the straight fixed type. There is also a mattress chamber, which is so constructed as to enable mattresses to be deposited into the fire without undue handling. After the cells, the engine-room was visited. The horizontal single-cylinder condensing steam engine for driving the main shaft, &c., capable of exerting 70 brake horse-power when working non-condensing, and the single-acting double-cylinder high-speed engine used for lighting purposes were both inspected. This latter engine is coupled direct with a Crompton continuous-current dynamo, and is capable of giving an output at 100 volts. No gas is used on the premises at all, everything being illuminated by the electric light produced from the burning of the refuse, without the aid of coal or coke. Finally the party were shown the mortar mills. Fifty tons of clinker are formed every day in the cells, and for dealing with this two mortar mills, a concrete flag-making plant, and a clinker-breaking and screening plant have been erected. The clinker is brought direct from the cells in side-tipping hopper wagons. The destructor is worked with a minimum of nuisance. The flues and arches do good work in creating such intense heats that all offensive

odours are completely destroyed in the burning of the refuse, and in addition a large dust-catcher, made by means of a specially long flue chamber, passes round the steam boilers and under ground for a considerable distance. The visitors from other towns took a great interest in everything in connection with the destructor, and satisfaction and even admiration were expressed freely in regard to the economical but thoroughly effective manner in which the work is carried out.

After photographs had been taken of the party the conveyances were again brought into requisition, and a start made for Kelham Island, to go over the Corporation tramways power station there. The visitors were met by Mr. A. L. C. Fell, M.I.E.E., general manager of the Corporation tramways, who, together with Mr. Yerbury, the assistant electrical engineer at the station, and Mr. A. H. Lowe, the mechanical engineer, conducted the party over the premises. Dr. Manton also joined the group here. The great generating engines attracted much attention, whilst interest was shown in the ammeters, which measure the amount of power being used by the cars running on the various sections of the tramways. The difference between the steadiness of the indicator of the ammeter for the Tinsley section and the fluctuations, amounting to as much as 100 ampères at a time, in that for the Walkley section, excited a good deal of surprise, and gave those present a fair demonstration of the hilliness of the Walkley route. A visit was also made to the basement, where, after much subterranean dodging of pipes, cylinders, &c., more boilers were shown, and also the cables along which the electric power is carried to the trolley wires.

Leaving the power station, the party next proceeded to the Westminster Hotel, where lunch was served.

After luncheon the quarterly meeting of the Association took place in the ante-room of the Council Chamber at the Town Hall. Mr. J. M'Taggart (Bradford) presided. The minutes of the previous meeting were read by the Hon. Secretary (Mr. W. Brockeman), and were unanimously adopted. It was announced that the date of the annual meeting had been fixed for from June 26th to June 29th, and that it was to be held in the city of Liverpool. It was resolved that the following five gentlemen should be asked to read papers at this annual meeting:—Messrs. Brockeman, M'Coll, Plant, Holt, and Smith.

Mr. Jackson proposed that Mr. J. C. Davidson and Mr. B. Brammer, both of Sheffield, should be elected as associate members of the Association. This was carried.

Mr. Jackson proposed that at the annual meeting Mr. M'Arthur, of Dundee, should be proposed as president of the Association for the ensuing twelve months.

Mr. Darley (Leeds) said that he thought this rather a strange request, as Mr. Jackson was himself in the running for the presidency. Did he understand that Mr. Jackson waived his claim to the position for next year?

Mr. Jackson said this was so. The annual meeting next year was to be held in Scotland, and he thought it more appropriate that Mr. M'Arthur should be the president on that occasion.

Mr. Downey, the treasurer, asked whether the banking account might be transferred from the Sheffield and Hallamshire Bank to the Yorkshire Penny Bank.

He was authorised to do this.

This concluded the business.

The delegates then adjourned to the Council Chamber for the purpose of hearing a paper read by Mr. James Jackson, Superintendent of the Cleansing Department of the Sheffield Corporation, on the subject of "Cleansing Work in Sheffield."

Mr. Jackson commenced by referring to the rapid growth of the city during the past ten years. The present area of the city was 19,651 acres, and this in October would be augmented to 23,266 acres, which he believed would be larger than that of any other provincial city. Further, the city contained 80,500 houses, and of this number no fewer than 9000 had been erected during the past four years. The number of loads of house refuse removed was 158,000, and this was increasing by about 8000 loads per annum. The work of the cleansing department in Sheffield practically never ceased, the whole of the machine street sweeping and removal of house refuse being carried out at night, while streets were hand swept and watered during the daytime. Cleansing work in all towns depended entirely upon local conditions, and he knew of no town where the conditions were more marked than they were in this city. Sheffield was built "without back streets," the result being that in almost every case refuse had to be brought a considerable distance before it could be put into the cart. In thousands of cases, too, steps had to be contended with. The only cities which could be compared with Sheffield were those built on the flat system, like Glasgow and Edinburgh. Nearly three-quarters of the ashpits of the city were on the privy-midden system, and the work of collection was consequently often carried out under most unpleasant conditions. The Corporation, however, were converting old middens at the rate of about 235 per annum, and all new houses were compelled to adopt the water-carriage and dry ashpit system. The advantages and drawbacks of the portable bin system were next dealt with by the speaker. He said that he was thoroughly in favour of the system for the majority of the large towns, and the present system of working in Sheffield being decidedly wrong, the sooner steps were taken to put it on a proper basis the better. The bins could not be introduced into this city to be as cheap as the fixed dry ashpit system; but from a sanitary point of view the difference in cost was over-weighed. He was sorry to say that the means of disposal in Sheffield were very limited. They had two tips, one siding for loading wagons for farmers, and one destructor. The Council had decided on the erection of another destructor at Penistone-road, and a commencement had already been made with the building of this. A third site had also been purchased for the erection of a six-cell destructor at Crookes. They at present collected about 500 tons of refuse daily in the city, and when the two proposed destructors were completed, he thought it probable that they would still have 150 loads per night going to tips, and it would be necessary to erect two more destructors. Mr. Jackson proceeded to give some particulars in regard to the working of the Lumley-street destructor, and then spoke briefly on the street cleansing of the city. Sheffield had about 320 miles of paved streets, he said, and with the exception of two small districts at the west end of the city, they were all cleansed by the Cleansing Department. He believed that they had a greater length, both of macadam roads and of wood paving than any other town—two extremes which made the work of street cleansing very difficult. The wood pavement had to be watched with the greatest care, while the large amount of *débris* to be carted from macadam roads during heavy seasons was sufficient to upset any system of street cleansing, particularly if a few main roads were in a bad condition. The department employed 605 men and 258 horses, and as showing the busy traffic which prevailed in some of our streets, he said that from records taken, as many as 6000 vehicles had passed certain points within eight hours. Like the disposal of house refuse, an ever-increasing difficulty was found in procuring easy places for the disposal of sweepings. Until quite recently they had been favoured with a tip not far from the centre of the city, but this was now closed, and his committee had had to purchase about fourteen acres of land for the purpose, at a cost of £6200. The

new tip was a distance of two miles from the city. In conclusion, he said that many Authorities owned and worked their own tramways, and no better way could be adopted than by using this means of haulage. It was necessary that sweepings should be taken as quickly as possible from the streets, and, seeing that most tramways were practically free from midnight until about six a.m., advantage should be taken of so ready and quick a means of transit. If the traction was electric it was necessary to keep the boilers working the whole of the night, and a little extra fuel would take the load of sweepings. Convenient loading shoots throughout the cleansing area would be needful, the refuse being tipped direct from the wagons into the trucks. Municipal progress had made rapid strides during recent years, and it was pleasant to notice a disposition on every hand to give more attention to what was regarded as the most important part of the work of a Local Authority.

The usual votes of thanks terminated the proceedings.

BUILDING TRADES EXHIBITION.

[Fourth Notice.]

The utilisation of the refuse of towns for practical purposes has been admirably solved by Meldrum Brothers, of Manchester. There is no reason why any township should not have its own electric installation and obtain the power from its own dung heap. At Hereford the sewage farm is now worked entirely with power from refuse, and the saving in coal alone is £450 per annum. Messrs. Meldrum have erected an electric installation at Darwen and also a refuse destructor, which supplies the power to light the town. Messrs. Meldrum had a model of the Darwen installation of their patent regenerative refuse destructor at the Building Trades Exhibition. It appears that alongside the electricity works, so as to make the steam main as short as possible, is the refuse-destructor plant. The slope in the site of the ground was specially useful in planning this installation, as it made unnecessary the construction of an inclined approach. The front of the refuse destructor was, for the sake of appearance, built of brick, but the rest of the building is of corrugated iron fixed upon a strong angle and tee iron framing supported by cast iron columns. Iron has been used throughout, as it was necessary to have the building absolutely fireproof, and to make it possible to wash it easily and thoroughly. The refuse is carted to the approach road in no less than five different ways, so that this traffic, which, if concentrated in one or two thoroughfares, might be deemed objectionable, is so scattered that it does not form a noticeable feature in any one street. On entering the destructor yard the carts are driven directly on to the upper floor or tipping platform. This occupies the full extent of the building, entirely covering the destructor cells and boilers below. The platform measures 100ft. long by 30ft. wide. Plenty of room is thus secured for unloading the refuse into the hoppers, the carts being driven in as they arrive, backed up to the hoppers, into which the loads are tipped without any manual labour. The work of unloading is thus performed in a few minutes, and considering the nature of the refuse there is surprisingly little dirt or odour about the building. The floor of the tipping platform is formed of concrete and steel joints carried by the iron pillars supporting the building. The upper surface of the floor is hardened by two layers of specially-made hard Limmer asphalt. This gives a hard, smooth, and very durable wearing surface, which can readily be cleaned. Good light and ventilation is obtained by a glass and zinc clerestory roof, extending the full length of the building. The hoppers are all on one side, and have sufficient capacity for one day's supply of town refuse. A circular staircase leads down from the tipping to the ground floor, where the cells, boilers, and other apparatus is placed. On the right, as one descends the stairway, is the lower part of the refuse hoppers, from openings in which the refuse is now shovelled by hand into the destructors just opposite. Besides the ordinary refuse, the fish offal from the market, and that from the public abattoirs, is consumed. It is thrown on the fire from iron pails holding about 80 lb., and although the fire is temporarily deadened it is not sufficiently interfered with to affect the supply of steam. With the normal tramway or lighting load taken singly it is unnecessary to use any coal.

Messrs. Pullman and Mann, of Leeds, exhibited—in addition to their brick, tile, and sanitary brick machinery—their patent steam cart, which comes under the Motor Cars Act, and carries up to five tons. This cart burns ordinary gas coke, does not damage the road, requires no licence, and only one man is needed to attend. Sanitary and Municipal Authorities might find use for steam carts in distribution from their brick, coal, and stone yards.

Mention was early made of the special exhibits drawn together under the auspices of the proprietors of the *Surveyor;* and as a matter of fact notices appeared of the wares of the principal exhibitors. The Chloros distributor was described and illustrated recently; also the exhibits of the Albion Clay Co., Messrs. Ham, Baker, and Co., E. Allcott, Ames Crosta Co., Septic Tank Syndicate, &c. But, in addition, Mr. J. Smith, of Coldharbour-lane, had forwarded some samples of stoneware pipes, bends, junctions, &c., fitted with Mr. Ernest Smith's patent joint, in which an iron socket and spigot is applied to a butt-ended stoneware pipe by means of imperishable cement. There were several exhibits of great interest to surveyors and builders, but the most attractive was the level used by the late Thomas Telford, the famous engineer, in constructing the military road between Edinburgh and London.

In the Gallery Annexe, which was also the reception room of the Institute of Clayworkers, were displayed on the walls a great number of architectural drawings, which were no doubt of considerable value to students and others.

The Smoke Abatement Exhibition was held in King Edward's Hall, but the specialities were neither new nor original, and are as familiar to our readers as household words.

Fire prevention found representation in the Minor Hall, and comprised twenty-one exhibits. Sections were shown of Columbian fireproof concrete floors as constructed of patented ribbed steel bars and stirrups embedded in concrete, and a section showing the method by which columns, stanchions, and joists are cased in with concrete. Silicate cotton, or slag wool, was shown by Messrs. J. C. Broadbent and Co., and the uses to which it is applied, shown in fireproofing partitions and floors. This slag wool is a pure mineral fibre made from Cleveland blast furnace slag, and is able to resist sound, fire, frost, and vermin. Loose slag wool may be sandwiched between wire-netting, and also in combination with plaster. Similar models were shown by F. Jones and Co., D. Anderson and Sons, and F. McNeil and Co. The New Expanded Metal Company had a useful display; and also the Mural and Decorations Syndicate, Limited, in the application of their patent terra-cotta and wire-lathing for fireproof partitions. The British Luxfer Prisms were again to the front as in Central Hall, and also the Fireproof Partition Syndicate, Limited, who exhibited a very neat and effective gate-keeper's office, the whole constructed of dovetail corrugated metal sheeting. Messrs. J. A. King and Co. showed their "Mack" patent fireproof and sound-proof slabs and blocks as used for forming

partitions, floors, ceilings, &c. The slabs have hollow reeds embedded in a specially-prepared plaster. Non-inflammable wood and fabrics were subjected to severe tests, and a section of Pease's fire-resisting cross flooring, and a small working model were in evidence. Altogether this section was very attractive.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

The dissemination of knowledge as to the character and size of the infinitesimally small organisms which perform such marvellous work in the bacterial purification of sewage proceeds slowly after all, and one hears some very funny, albeit quite true, stories anent this prevailing ignorance. As further illustrative of this, the manager of a well-known sewage works on the bacterial system has been good enough to send me a letter which he recently received, which runs as follows: —"Can you let me have some bacteria to put into a sewage tank on Wednesday morning? I know these animals will breed themselves, but I want some if you can send them to make a little show"! This gentleman evidently fancies that bacteria are a sort of cockroach, and can be obtained at so much a dozen, whereas they are so minute—being no larger than from $\frac{1}{3000}$th to $\frac{1}{25000}$th of an inch—that they are never visible to the naked eye, but require the most powerful microscope for their discovery. I am not told whether these animals were packed off as requested.

I observe that a number of local surveyors in the Thames Valley have announced that they have formed a local organisation under the title of The Lower Thames Valley District Surveyors' Association, for the purpose of discussing matters and practice as affecting the areas of their several Authorities, more especially the administration of bye-laws and regulations, and for securing uniformity of procedure in relation to gas, water, electric light, and tramway companies. The idea is not a new one, as I have heard of several instances where, for some years, surveyors of neighbouring Authorities—to the number of about half a dozen—have grouped themselves together for a similar purpose, and held monthly meetings without ostentation or public notice alternately at each other's houses, and discussed over "a pipe and a friendly cup or glass," the intricacies of building bye-laws, so as to lead to a common interpretation of such bye-laws, and generally for the discussion of matters affecting their districts, to the great advantage of every one concerned, and also that of the districts affected.

I am not sure whether the objects and usefulness of these friendly meetings are not better secured by restricting the number of members so as to limit them to friendly "parlour" gatherings where the proceedings are informal and without restraint and rules rather than to extend them to formal discussions and the reading of papers, but I would suggest that the multiplication of these friendly associations be extended for the mutual benefit of surveyors, who would derive much pleasure and enlightenment from them. The newly-formed association announce that "it is not in any way intended to clash or interfere with the work of the parent organisation," from which one gathers that the Incorporated Association of Municipal and County Engineers is meant. It is not quite obvious as to why they should have been so anxious to disclaim this, except to utilise it as a negative way of censuring the Association, and from what I hear this is the generally-accepted view in which it is held.

I have from time to time voiced the opinions of members of this Association in this column as to the neglect of their interests, and of the lack of capacity of the Council in initiating any measures to extend the usefulness of the organisation. It is an unpleasant feature — which the Council should strenuously endeavour to correct—that there is widespread dissatisfaction among the members as to the mismanagement of the Association, and as business men the condition of affairs reflects adversely upon them. Whilst pointing this out, I am bound to say that the individual members cannot shift the whole responsibility on the Council. The latter are elected by the votes of the members, and are therefore their creation. If the Council do not acquit themselves of their duties to the satisfaction of the members, the latter should nominate and elect men independently of those suggested by the Council. New blood is urgently required, and a fair proportion of the Council should be composed of younger men rather than that it should almost entirely consist of men who have grown grey in the profession. Inasmuch as the election of the new Council for 1901-2 will take place almost immediately, nominations should be sent in without delay if members are in earnest.

It is interesting to observe how the gentlemen with a mechanical "bend" have taken the opportunity created by the introduction of the bacterial system of sewage disposal to turn their inventive capacity to account in designing apparatus for the automatic charging and discharging of bacterial beds. Messrs. Cameron, Commin, and Martin, of the Septic Tank Syndicate, were the first to bring out a patent which, as is well known, is on the bucket principle. Then followed Mr. S. H. Adams (Messrs. Adams and Co.), York, with their system of controlled syphons; and Messrs. Mather and Platt, Manchester, with valves set in a chamber opened by a cam-and-ratchet arrangement actuated by the rise and fall of sewage in a storage tank; Mr. C. F. Dixon, of Low Hall Mills, Holbeck, Leeds; and now Mr. Joseph Graham, of Bank-chambers, Bank-street, Carlisle, has introduced an apparatus which he claims to be simple in working, and that by its use there is no loss of head. Municipal engineers have ample choice as to the kind of apparatus which will best suit their requirements.

I have before this acquainted my readers with new methods for obtaining high pressure gas in incandescent lamps for lighting refuges and open places. Progress with the development of intensified gas lighting is rapid; and, light for light, electricity is now considerably behind gas when cost is also taken into account. The latest departure of which it is necessary that my readers should be kept informed is the Scott-Snell self-intensifying gas lamp for street lighting. Hitherto where intensified gas has been introduced the means of obtaining the required pressure has been by a water-motor or other apparatus, and the employment of a second set of pipes. This meant that the system was only available and practicable in large open spaces, railway stations, &c. Mr. Scott-Snell has, however, improved greatly on this, and his lamp requires no mechanical compressor, and yet it is capable of supplying gas at any pressure from 4in. to 20in. The power is derived from the heat of the burning gas, and is generated in each individual lamp. There are practically no mechanical moving parts, and the apparatus is extremely simple. The lamp may be fitted to any existing column, and its cost is not prohibitive. It is manufactured by the Scott-Snell Phillips Syndicate, Limited, whose offices are 51, Victoria-street, Westminster, S.W., to whom my readers should apply for further particulars. I am of opinion that this system has a good future before it. Senex.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

AND

Journal of Sanitary and Municipal Engineering

MAY 16, 1901.

REFUSE REMOVAL AND DISEASE.

WITH the hot summer days close upon us, bringing in their wake an increased liability to outbreaks of diphtheria, and the inevitable visitation of summer diarrhœa, the question of improved systems of refuse removal is once more brought into prominence. Many Sanitary Authorities have already had the matter brought under their notice by their Medical Officers, and we feel called upon at this juncture to impress upon those who have not yet moved in this direction the urgency of doing so without delay. Prompt action may mean the avoidance of many ills which would otherwise result in the event of neglecting such simple precautions as are generally recommended for adoption. A timely note of warning comes from the borough of Hampstead in the shape of a report of Dr. E. Gwynn, Medical Officer of Health for the district, who urges in the strongest terms the necessity for making a collection of dust and house refuse twice a week during the summer months instead of once a week. He emphasises his recommendations by pointing out that there are 152 blocks of flats in the borough in which the refuse is generally stored in a well-like courtyard, from which the effluvia rises and passes into the bedrooms. That he has good reasons for insisting upon this additional precautionary measure is made evident by a case which recently came under his notice in which an outbreak of diphtheria occurred where the dust-bin was in the proximity of the children's playground. Although the recommendation in question was practically limited to flats, tenement and registered houses, and public institutions, Dr. Gwynn expressed the opinion that it would be well for the Council to go a step further and consider the advisability of undertaking a twice-a-week collection for the whole borough—a question which will have to be considered in the near future. Of course, the report has yet to be considered, but we feel certain the Borough Council of Hampstead will act upon its recommendations; indeed, we hardly fail to see how they could well do otherwise. With such an example before them, other Councils should not be behindhand. Hampstead is far from being the only borough where a similar need exists, as the annual reports of Medical Officers show. As might be expected, there are members of public bodies who will make it their object to cavil at any extra expense incurred by the process of a more frequent collection of house refuse, and a case in point has just occurred at Chingford. Here a somewhat similar recommendation, backed up by both the Medical Officer and the Sanitary Inspector, was made the subject of a lengthy discussion, in the course of which it was evident that a trifling saving in pounds, shillings, and pence, was considered by the majority far and away paramount to considerations of public health. This was what the opposition amounted to in effect. Common sense, however, asserted itself in the remarks of Dr. Cruickshank, who pointed out that the Council had to look after the health of the parish, and all sanitary matters should receive consideration when brought forward. The mover of the amendment, he went on to observe, said that sanitation was not the point before them, but he submitted that this was the point, and that they should take notice of it in view of twenty or thirty cases of infectious disease. Another speaker drew attention to the fact that the Council paid £199 5s. last year for the isolation of infectious cases, a large part of which might, in all probability, have been saved had the refuse been collected weekly. In the end the amendment was carried, and the matter went back for further consideration. No doubt there will be the usual delay in such cases, while in the meantime, if hot weather sets in, the accumulated rubbish will be allowed

to pollute the atmosphere and breed fresh cases for the isolation hospital. We have dwelt upon this particular case as likely to be typical of many others in this country, and it only furnishes another example of the anomalous position of the Medical Officer of Health under present conditions. It is nothing short of iniquitous that men of education and experience in these matters should have their recommendations set aside in this way. What is the use of the Medical Officer of Health at all, unless his directions in a simple yet important matter of this kind are carried into effect?

Lectures to Health Officers.

The series of lectures now in course of delivery at Leeds, under the auspices of the West Riding County Council, promises to be one of the best things yet done by the county Authorities to help Sanitary Inspectors and others in the more efficient performance of their duties. We are glad to announce that it is intended to give them a wide circulation. In addition to their publication in the columns of The Sanitary Record, they will be reprinted and published at a nominal price. The lecturers are all well-known and experienced men, and they are treating their subjects in a thoroughly up-to-date manner. In this way all aspiring to positions in the sanitary administration of the country will have placed before them the very latest practice, and will receive material assistance in preparing for examination under the various certificate-granting Boards and societies. But we are hopeful that the action of the West Riding Council will have a still greater influence, and that other counties will be encouraged to follow the example thus set. We rejoice to know that a similar movement has been started in New South Wales. The chief health officers of Sydney, with the sanction of the City Council, are making arrangements for the initiation of a systematic course of lectures on practical hygiene, and all subjects appertaining to public health, to every municipal employé who cares to avail him or herself of the opportunity. The Mayor has entered most heartily in the project, for he believes that it is only by such means that the "Municipalities in the metropolitan area will become supplied with officials who are able and efficient in sanitary matters." Cannot the London County Council arrange for some such work to be undertaken in the autumn of the present year? The cost would be small, but the benefit would be exceedingly great.

An Indian Town.

It is well that those at home should be kept alive to the great work that is needed in India. To fight famine and plague it is not necessary to increase our armies and military establishments. India needs more peaceful measures. Every paper that comes to us tells the same story. Sanitary works are the need of our distressful subjects, and until these are increased, plague, pestilence, and famine will continue their dire destruction. One extract from this week's mail will suffice to emphasise this point. It is only one of many. We are told that the town of Nellore is in a dreadfully insanitary condition. Major Grant, I.M.S., Deputy Sanitary Commissioner, in his inspection notes calls attention to several grave sanitary defects, of which the chiefest would appear to be the fouling of the water-supply of the Nellore tank by fæcal matter and the burning of corpses near one of the supply channels. As the Sanitary Commissioner sarcastically says, there are ratepayers in the town, who use the Nellore tank, who would feel grateful if the Council no longer required them to drink water in which fæcal matter is an unnecessary addition, and there may be others who, using the river water, might be pleased to know that they are not imbibing a solution of corpses. Both the Deputy Collector and the Collector endorse the remarks, and suggest that the Municipality should be ordered to report periodically on the steps taken to remove these sanitary defects. The Collector says that the water supply and drainage for Nellore have long been pressing necessities, and suggests that steps, such as raising the maximum of taxation, should be taken to remedy these defects.

Rochdale Sewerage.

It looks as if matters were at last coming to a head over the dispute between the Rochdale Town Council and Mersey and Irwell Joint Committee. The latter has long complained of the character of the effluent discharged from the sewage works of the town in the stream under its control. Nor have the Rochdale people been unmindful of the defects of their system. Many hundreds of pounds have been spent in experiments to try and find a remedy, but up to the present they have failed to satisfy the demands of the Committee. Last February the Town Clerk wrote to the Committee giving an outline of a scheme, and giving approximate estimates for an installation of bacteria beds for dealing with the sewage of the borough. But it was also pointed out that if these plans were adopted an expenditure of £40,000 would be involved, and therefore the Town Council asked for time to continue experiments so that the efficiency of the trial beds might be fully demonstrated before this large expenditure was undertaken. In the intervening time the estimated expenditure has reached £50,000, and still the Town Council cannot make up its mind what to do. Under the circumstances, the Rivers Committee at its meeting last week threatened to apply for a summons, and it was only on the urgent appeal of the local representative that action was deferred for a month. This further extension will be the full limit granted by the Committee, and it is to be hoped the Council will realise that it is useless to delay action any longer. We fully admit the difficulties of dealing with the sewage of manufacturing towns. Each one has its peculiarities. Yet too much time may be exhausted in experimenting, and often it is only made the excuse for delay. Of course the heavy expenditure is not a pleasant prospect for Rochdale, but then the Town

Council knows that it is inevitable, and the longer the decision is delayed the more expensive will the work become.

A Vacancy at Cape Town.

The methods of doing business by the Council of Cape Town have been subjected to very strong criticism from time to time. At last, however, this body appears to realise that other than local responsibilities rest upon its shoulders. Just now, considering the enormous traffic passing through the place, Cape Town occupies an absolutely unique position, and it is of the utmost importance that its health bill should be kept as clean as possible. Dr. Fuller, for various reasons, has resigned the Medical Officership, and the Town Council has decided to advertise in England for a successor. This action has been condemned by some of the Little Africanders, who appear to think that the district contains plenty of men qualified for the post. To a certain extent this may be true, but with plague and small-pox in its midst, the town requires the services of a man of the very widest experience, and also one who is entirely independent of local influences. But the salary offered is insufficient for the enormous responsibilities accompanying the office. True that £800 is £200 more than was originally recommended for the position, but it is not enough to entice men from the comparative safety of a home practice to the deadly surroundings of a country into which the very dregs of humanity are being deposited. It is worth at least £1000, and even then for the man to be successful he must be backed up by a good assistant and an efficient staff of Inspectors. As we have stated, Cape Town is no ordinary place. Its existence depends upon its commercial supremacy, and let its harbour be closed because of plague and disease, there is nothing but decay and ruin before what should be the first town in South Africa.

Heavy Mortality Rates in Edinburgh.

Sir Henry Littlejohn's report on the health of Edinburgh during the month of April shows an exceptionally high death-rate owing to an epidemic of measles and whooping-cough. The average rate for the corresponding month during the last five years is 18·75 per 1000; this year it is 22·34. The only year of the past quinquennium in which the rate for the month stood higher was 1897, when the rate was 25·20, the abnormal mortality being due to the very same causes. The total number of deaths in Edinburgh last month was 569, the principal causes being phthisis (47), other forms of tuberculosis (24), other chest diseases (196), measles (31), and whooping-cough (59). The deaths from the causes named reached a total of 357, as against 248 due to the same causes in April of last year. Sir Henry points out, as a feature of some interest, that of the 31 reported deaths from measles, only 8 occurred in the City Hospital, while only 5 deaths from whooping-cough occurred in the hospital out of the 59 reported. In another return, dealing with the intimations of infectious diseases, he brings out the rather striking fact that 1100 cases of infectious disease were reported in April, as compared with only 369 in the corresponding month of 1900, and that out of this total of 1100, no fewer than 1013, or only 87 short of the entire number, related to measles. The average number of intimations during the previous five years was only about 600, although in 1897, the year already referred to, they reached 1830 in number. These are some of the most salient features of a very interesting report.

The Malaria Investigations.

The Liverpool School of Tropical Medicine has issued a statement on the subject of the prevention of malaria in tropical countries, which summarises the knowledge acquired from the most recent investigations. The principal difficulty in prosecuting experiments hitherto has been the want of funds; but it is now announced that a leading citizen of Glasgow has placed at the disposal of the School and of Major Ross a large sum of money, sufficient for one year's thorough trial in some malarious city. A staff of workers is accordingly to be despatched by the School, who will attack the mosquito both in its adult form and as larvæ in pools of water, with the ultimate hope of practically exterminatting the pest. The selection of the town has yet to be made.

National Health Society.

OFFICIAL TRANSACTIONS.

Lectures at 53, Berners-street, W.—The special lectures organised by the Association of National Health Workers were continued during last week as follows:—On Wednesday, May 8th, Dr. Gay lectured on "Disinfectants," Dr. Christopher Childs acting as chairman on this occasion. On the following day, at 5.15, Dr. Robert Bowles gave a most interesting lecture on "The Physical Relations of the Tongue, Nose, and Throat in various States of Unconsciousness." Mr. Bowles demonstrated in a most convincing manner the superiority of the Marshall-Hall method over the more generally adopted Sylvester method in the restoration to life of those apparently drowned. He showed how the position of the unconscious patient was often a matter of life and death, how the mere fact of moving a patient from off his back on to his side would, in some cases, be the means of saving his life. This lecture will be reported as fully as possible later, but as Dr. Bowles used several carefully-prepared diagrams and various apparatus, members of the Association who are interested in the subject, and who were unable to attend the lecture, are advised to read Dr. Bowles' book, "Stertor and Apoplexy," published by Baillière, Tindall, and Cox, the book being fully illustrated by diagrams, &c. Dr. Owen Lankester took the chair at Dr. Bowles' lecture. In the evening of the same day Dr. Squire lectured on the "Open-air Treatment of Consumption," or, as he prefers it called, the "*Hygienic* Treatment of Consumption." On Friday evening Dr. Steegmann lectured on "Vaccination," Dr. Kenwood taking the chair.

Sanitary Inspectors' Associations.

NATIONAL UNION.

A CONFERENCE of the North-Western District Centre of the National Union of Sanitary Inspectors was held on Saturday afternoon in the Co-operative Hall, Manchester, Mr. James Mort (Lynn) presiding. Mr. F. J. Rowe (Sanitary Inspector of Manchester) read a paper on "Bakehouse Reform," in which he spoke of the changes which had taken place in this district in this matter. He discussed the law relating to bakehouses and dwelt on the prospects of the future, referring in conclusion to the possibilities of co-operative action in the way of reform. A discussion followed.

THE SANITARY INSTITUTE.

AT an examination in Practical Sanitary Science, held at Sydney, N.S.W., on January 12th and 19th, 1901, three candidates presented themselves. A certificate has been awarded by the Council of the Institute to the following candidate:—F. W. Lawson.

At an examination for Inspectors of Nuisances, held at Sydney, N.S.W., on January 12th and 19th, 1901, forty-nine candidates presented themselves. Certificates have been awarded by the Council of the Institute to the following candidates:—F. W. Barber, T. Connell, E. Cresswick, F. A. Cuddy, F. Davis, R. M. De Carteret, J. Duncan, A. E. Field, R. A. Fraser, W. E. Gundry, T. A. James, T. F. Joyce, K. B. Kenway, G. T. Law, F. Letchford, B. Lloyd, T. A. Lloyd, J. V. Lovegrove, P. Murphy, D. Owen, J. P. Palazzi, F. J. Paris, J. J. Skelton, J. D. Smith, F. G. Tuck, A. E. Wadsworth, H. G. Wills, J. J. Wright.

At an examination in Practical Sanitary Science, held in London on April 26th and 27th, 1901, twelve candidates presented themselves. The following candidates were awarded certificates:—F. Elgar, G. B. Grave, K. Gray, P. B. Sands, R. Wood.

At an examination for Inspectors of Nuisances, held in London on April 26th and 27th, 1901, 113 candidates presented themselves. The following candidates were certified, as regards their sanitary knowledge, competent to discharge the duties of Inspectors of Nuisances under the Public Health Act, 1875:—Miss J. Agnew, A. Anderson, W. A. Austen, W. J. Barker, G. F. Barnes, S. P. Beal, Miss E. I. Beeston, Miss M. G. Bhose, Miss A. E. T. Biggs, S. T. Bocock, A. E. Bonham, A. Burgess, J. J. Burgess, W. J. Burrows, C. E. L. Canham, R. E. Clarke, J. S. Clements, J. Cooper, L. Crawshaw, W. Fanner, C. W. Fisher, Mrs. T. Fisher, D. J. Ford, F. F. Fulker, R. H. L. Grontage, G. B. Hartfree, M. J. J. Hillyard, Miss M. F. Hoc, A. W. Holley, H. C. Hunt, J. Jackson, W. Jones, J. J. Kennan, R. R. Knight, W. G. Lane, A. W. Lucas, H. Martin, A. Matthews, C. Mitchell, P. Morgan, T. L. Morley, G. L. Murray, T. B. Phillips, T. E. Phillips, A. E. Platford, J. W. M. Rapley, W. Scothern, F. Sheriff, T. V. Smith, E. J. G. Sinnett, J. Thomson, C. D. White, J. E. Whitehead, R. Wickham, D. W. Windmill.

At an examination for Inspectors of Meat and other Foods, held in London on May 3rd and 4th, 1901, nine candidates presented themselves. The following candidates were awarded certificates:—A. J. Hocken, Veterinary Lieut.-Col. J. A. Nunn, F.R.C.V.S., D.S.O., C.I.E.; J. Roberts.

THE Cleansing Committee of Aberdeen Town Council has agreed to recommend the construction of a lavatory in the vicinity of Torry Harbour, at a cost of £400. It has also been resolved to construct a lavatory near Wellington Suspension Bridge, between Menzies-road and Wellington-road, at an expenditure of £425. The Committee further sanctioned the construction of a lavatory in Hutcheon-street, opposite the new dead meat market.

Public Works.

SEWERAGE.

THE Northwich Rural District Council has decided to apply to the Public Works Loan Board for a further advance of £1000 for the Winnington sewerage works.

THE Halesowen District Council has decided to apply to the Local Government Board for sanction to an additional loan of £1438 required for the completion of the Hill sewerage system.

THE Bridlington Council has received sanction to the borrowing of £5960 for the purposes of a main drainage scheme prepared by Mr. E. R. Matthews, C.E. The work is to be proceeded with at the close of the season.

AT the last monthly meeting of the Quorn Urban District Council, it was resolved that Mr. Simpson's sewerage scheme be accepted, and that formal application be made to the Local Government Board for sanction to borrow the necessary sum to carry out the proposed works.

A LOCAL Government Board inquiry has been held at Branksome by Colonel A. J. Hepper, R.E., D.S.O., into an application by the Branksome Urban District Council for sanction to borrow £1687 for the purchase of land for purposes of sewage disposal. The purification works will be on the septic tank system.

LEEDS has been placed in a perplexing position by the rejection of the sewerage scheme of the Corporation by the House of Lords Committee. The Gateforth estate was purchased for £85,000 to carry out the scheme, and the Corporation had obligations with the West Riding Rivers Board which cannot now be fulfilled.

THE Hanley Town Council has accepted the tender of Mr. W. Williams for the provision of an additional settling tank at the sewage works, amounting to £1560, and has decided to make application to the Local Government Board for permission to borrow £4000 required for this, and two new boilers and extensions to the boiler-house at the sewage works.

THE proposals of the Burton Corporation Bill were further considered last week by the Select Committee of the House of Commons. Evidence formally proving the preamble was given by Mr. Whitehead, the Town Clerk, and Mr. Lyneham, the Borough Engineer, and, the preamble having been declared proved and the clauses adjusted, the Bill was ordered to be reported for third reading.

AT the annual meeting of the Ledworth and Mellon Sewage Board it was stated that, acting on instructions, Mr. Garside, the engineer, had altered the plans, &c., of the sewage outfall works, bacteria beds, &c., so as to reduce the first estimates of £9000 to over £7000. The Board instructed Mr. Garside to proceed with the alterations, and prepare his plans, &c., for formal inspection and approval by the Local Government Board.

A LOCAL Government Board inquiry was held at Romford last week with reference to an application by the Urban District Council for leave to borrow £1100 for works of sewage disposal at the sewage farm, Britton's Farm, Hornchurch. Mr. Winmill explained the scheme, saying the present storage capacity was 600,000 gallons. The new tank would be used in times of storm, the object being to store the overflow at times when the land was full of water from the natural rainfall.

THE Gainsborough Urban Council has decided to submit for the approval of the Local Government Board a scheme, estimated to cost £24,281, for the improvement of the sewerage of the town. Its object is to avoid the flooding of the lower portions of the town when the sewer outfalls to the Trent are tide-locked. The scheme provides mainly for a large intercepting sewer in Trinity-street between the hills and the lower levels and various intercepting sewers in other portions of the town. It also includes a collecting sewer, which, when outlets are tide-locked for twenty-four hours—which has occurred twice during the last nine months—could be connected by opening a sluice to each outfall sewer, and discharging into a sump well, where a hydraulic engine could be provided to raise the sewage into the river.

At the last monthly meeting of the Heywood Town Council, the Health Committee reported the receipt of a letter from the Local Government Board declining to sanction loans for the purposes of the refuse destructor and works of sewerage in Rochdale-road, until the applications with reference to the Botany and Heap Bridge sewage disposal works had been investigated. It was resolved that the Town Clerk be instructed to obtain and forward to the Local Government Board the information required by it in connection with the excess expenditure on the sewage disposal works at Botany.

At the last monthly meeting of the Altrincham District Council it was decided to make an application for a loan for £15,000 for the new sewage works. A Committee was appointed to inquire further into the agreement relating to the public control of Hale Moss, and to report to the Council. Mr. Vernon, in moving the appointment of the Committee, stated that the agreement was not carried out, although it cost the Council £270, because of some unauthorised verbal alterations which made it objectionable to the various Authorities interested. It was important to know by whom these alterations had been made.

A Local Government Board inquiry has been held at Cotherstone by Lieut.-Col. A. E. Smith, R.E., to inquire into the proposal of the Startforth Rural District Council to borrow £2650 for the sewerage and sewage disposal purposes at Cotherstone. The village is beautifully situated at the junction of the rivers Balder and Tees, and is growing in popularity as a summer resort, and is particularly patronised by persons desirous of a change whose vocation necessitates their living near the coast. The Engineer (Mr. Parker, C.E., of Newcastle) explained the scheme, and there was practically no opposition, though a special drainage area was suggested by farmers who live in the parish outside the area to be sewered.

At a recent Bewdley Town Council meeting it was reported that a contract had been entered into with Mr. Reading, of Wolverhampton, for £10,590, for carrying out the new water scheme, and the work was in full swing. The Council sealed an agreement with the Rev. S. B. Pendyre for the water rights, &c., for £800, and £64 costs, the lease being for 2000 years at an annual peppercorn rent. The Town Clerk said the Public Works Loan Commissioners had agreed to lend the Council £9026 at 3¼ per cent. interest per annum, repayable in half-yearly instalments, and the balance of the money required for the waterworks had been secured by the selling of Corporation stock. The General Purposes Committee reported that Mr. Berrington, C.E., had been instructed to prepare a sewage scheme for Bewdley and for the district which might hereafter be attached to it, and would present a report as soon as possible.

The Kingswood District Council has received a letter from the Local Government Board in reference to the inquiry held by Mr. Fawcett into the application of the Council for sanction to borrow £27,000 for purposes of sewerage and sewage disposal, and also into the propriety of the works proposed to be constructed outside the urban district, and into objections which have been made thereto. The Board was advised that the land at Cowhorn Hill, in the parish of Oldland, proposed to be accepted as a site for outfall works, was unsuitable for the treatment of sewage, and it would appear from the evidence given at the inquiry, and from the account given by Mr. Fawcett of his inspection of the site, that it was otherwise open to objection. The Board therefore requested the Urban District Council to re-consider its proposal; and as it would appear that there are portions of the rural district of Warmley which require draining, the Board suggested for the consideration of the Urban District Council whether it would not be desirable for the two Councils to combine for the purpose of carrying out a joint scheme of sewerage and sewage disposal for the areas, which would be conveniently drained to one outfall. In the event of a joint scheme being adopted, it might be found practicable and desirable to connect the sewers of the Conham portion of the urban district with the general system, and thus avoid the cost of constructing, maintaining, and supervising separate outfall works for different parts of the urban district.

The inquiry into the application of the Burton Corporation for power to acquire an additional 98 acres of land on which to treat the town sewage, was continued by the Committee of the House of Commons. Mr. Richard Sale, chairman of the Repton District Council, Mr. Bailey Denton, an engineer with twenty-five years' experience of sewage disposal; and Dr. Barwise, Medical Officer of Health to the Derbyshire County Council, spoke in opposition, the two last named advocating the adoption of precipitating tanks. Dr. Thresh and Dr. Samuel Rideal also condemned the present system. The Committee decided to grant the powers asked for, laying it down as a condition that the County Council should have power to take samples of the sewage before and after treatment, and throwing out a suggestion that a belt of trees should be planted between the sewage farm and the estate of Mr. Mosley.

WATER.

The Corporation of Doncaster has notified Sheffield that in 1902 it will require 375,000, and in 1903 400,000 gallons of water daily from the new source. From Thyrberg reservoir it is now receiving about 450,000 gallons daily.

The County Purposes Committee of the Corporation of the City of London has submitted to that body a report as to the Royal Commission on the Water Supply's suggestion that there should be a Water Board formed, consisting of not more than thirty members. No direct representation of the Corporation of the City was proposed, and the Committee recommended that it should be authorised to wait by deputation upon the President of the Local Government Board with a view to making clear the Corporation's position and rights in that respect. This recommendation has been adopted.

The Rhymney and Aber Gas and Water Company have now commenced to construct their reservoirs at Blaen-Rhymney. It is estimated that the whole of the works will occupy about three years to complete. The site of the works offers a natural basin for the storage of water, there being a short valley tapering on to the fringe of the Breconshire county. In all there will be three reservoirs, but the contractors will first proceed with the largest of the works, which is naturally the lowest site in the valley. The necessary machinery is now being conveyed on to the ground, and upwards of forty huts are being built to accommodate the workmen. When completed the reservoir will be the main source of supply for the whole of the Rhymney Valley.

A very interesting visit of inspection was recently paid by a large number of members of the Ipswich Scientific Society to the Waterworks. After tea the party proceeded to the old engine-house, where Mr. Howlet Roberts, A.M.I.C.E., the Waterworks Engineer, read a descriptive paper. The machinery, which was in motion, was then inspected, and attention was drawn to the plan of the proposed new reservoir on the Park-road. It will have a storage capacity of four million gallons of water, the dimensions being 290ft. by 20ft. with a depth of about 11ft. The concrete walls will be 10ft. thick in some places, and are calculated to withstand a pressure of 17,000 tons without the earthen embankments. The cost of the work will be something over £20,000.

Fresh litigation is threatened between the Swansea Corporation and the contractors of the Cray Waterworks. We understand that Messrs. Paterson and Son have served a writ on the Corporation in the High Court of Justice to have it declared that their engineers are not entitled to interfere with the methods of the contractors in the carrying out of the work, particularly in the lining of the tunnels, and also that, owing to the largely-increased work required in the deepening of the main dam, the engineers are not entitled to withhold the time allowance certificate (alleged to be provided for the term of the contract) for an unreasonable time. The contractors are also applying for an injunction restraining the Corporation from taking any action pending the hearing of this action, and are, further, claiming damages for alleged breach of contract. The action which we understand the Corporation are contemplating is that of appealing to the Higher Court for power to determine the contract.

At a recent meeting of the West Riding County Council, the Sanitary Committee reported in reference to the Thorne water supply question:—"Pursuant to the resolution of the County Council at their meeting on the 13th March, 1901, your Committee have made a representation to the Local Government Board, under Section 19 of the Local Government Act, 1888, in respect to the unwholesomeness of the existing water supply of the town of Thorne, in which the whole facts of the case are set out."

A Bill to enable the Corporation of Southport, the Urban District Council of Birkdale, and the Rural District Council of West Lancashire to acquire the undertaking of the Southport Waterworks Company, was last week before a committee of the House of Lords, the Earl of Jersey in the chair. The company is now a large and prosperous concern, with a capital of £425,000, and Mr. Pope, who appeared for the Local Authorities, said they made no serious charges against the management. The company last year applied for powers to construct new works and to obtain additional capital, and Parliament gave the company power to raise two-thirds of this capital, which, however, was not to be taken into account by an arbitration dealing with the question of the price to be paid for the undertaking, should Local Authorities agree to form a joint board and to promote a Bill for the purpose in the present session.

A Lords' Committee, with the Earl of Jersey in the chair, last week, began the consideration of a Bill to empower the Corporation of Barrow-in-Furness to extend its water supply. It was explained on behalf of the promoters that the proposal was to take water from the river Duddon at a point 17 miles above the town. A low weir would be made to dam up the water, and the Duddon being a salmon river there would be a fish ladder to satisfy the requirements of the Fishery Board. The Corporation asked to be allowed to take 2,000,000 gallons a day when the flow of the river was more than 5,000,000 gallons. When the flow was between 3,000,000 and 5,000,000 gallons they sought permission to take all over 3,000,000 gallons; and when the flow was over 15,000,000 gallons they asked for 3,000,000 gallons. To meet the occasions when the flow was less than 3,000,000 gallons, a reservoir would be made at the Seathwaite Tarn, some three miles to the north-east of the proposed Duddon intake, and about midway between Coniston Water and Wast Water. The level of the tarn was to be raised by means of a masonry dam some 21ft. high, and this would increase its storage capacity by some 275,000 gallons. The Corporation proposal was to take these 275,000 gallons as well as 175,000 gallons from the existing capacity of the tarn, and the overflow from the reservoir would go down the existing tarn beck. The drainage area dealt with was 12,000 acres, and its average daily water flow was estimated at 54,000,000 gallons. Of this amount the Corporation proposed to take only an average of 2,750,000 gallons.

The Sheffield Corporation reservoir at Langsett—one of the largest works of the kind now in course of construction—is more than half finished. The most important part of the work lies in the construction of the embankment. When complete, this will be composed of no less than 900,000 cubic yards of material, of which about 80,000 yards are represented by puddle. The latter figures relate to the trench which is in the centre of the embankment, and which is the mainstay of the structure. Water may penetrate the other material, but it can never force a passage through the puddle trench. The trench extends many feet below the surface of the old river course, and below ground forms a foundation for the remainder, and an effectual stop to any water which should make a way below the puddle, consisting of a solid mass of between 30,000 and 40,000 cubic yards of concrete. This measures 9ft. in width. The trench, which is composed of puddle, commences on the level of the old river at a width of 38ft. at the foot, and diminishes at the rate of 1 in 12 until the top is reached, when the width will be 9ft. The width of the embankment at the top will be 28ft., and 230 yards at the bottom. Its depth will be 100ft., and length 396 yards. The concrete part of the trench has been made, and the embankment has risen, roughly, 45ft. above the surface of the old watercourse. Up to the present 150,394 cubic yards of excavation have been contributed towards the embankment, and 20,000 yards of puddle. Langsett reservoir will have a gathering ground of 5203 acres, and will hold between 1,400,000,000 and 1,500,000,000 gallons. To fill it will take 12in. of rain, and it would be possible to put in the complete amount of water within a couple of months, but this would never be done, as it is not advisable to let the water accumulate at the rate of more than 6in. a day. The reservoir will cover 125 acres, and will be by far the largest of those belonging to the Sheffield Corporation.

LIGHTING.

Haverfordwest is to have a new gasholder at the municipal gasworks.

The Darwen Corporation has decided to spend £15,000 in additional works and mains for electric lighting.

The London County Council has agreed to lend the Stepney Borough Council £5160 for street lighting purposes.

Gasworks extensions and improvements at Yeovil will cost that town £10,000. A loan is to be raised by the Council.

At a recent meeting of the Malvern Urban Council it was decided to seek official sanction for a loan of £17,000 for carrying out of an electric lighting scheme and other improvements.

The Gas Committee of the Manchester Corporation has increased the price of gas within the city area from 2s. 6d. to 2s. 9d. per 1000 cubic feet, and in the outside districts from 2s. 9d. to 3s. per 1000.

A special meeting of the Harrow Urban District Council took place last week, for the purpose of considering reports and estimates from the Surveyor referring to the Pinner-road and Sudbury-hill drainage schemes, the public lighting, and the improvement of various footpaths.

The annual report of the working of the Southport Corporation's Gas Estate shows a gross profit of £16,083, and after paying interest and sinking fund charges, there is a balance of £5583, plus £1323, brought forward. It had been anticipated that there would be £8000 to hand over for the relief of the rates, but owing to the high prices of all classes of material used this sum is not reached by £1092.

The Poulton-le-Fylde Gas Bill last week came before Lord Morley, Chairman of Committees of the House of Lords, as an unopposed measure. Its object is to transfer the undertaking of the Poulton-le-Fylde Gas, Coal, Lime, and Coke Company to the Poulton-le-Fylde Urban Council, and to authorise that Council to supply gas. Formal evidence on the preamble having been given, the Bill passed the Committee, and was ordered to be reported for third reading.

There is at present under construction at St. Anthony's, for the Newcastle and Gateshead Gas Company, an immense gasholder, and some idea of the size may be realised from the facts that the work will cost £77,000, and that the holder itself will be in three lifts, each of a capacity of 15,000,000 cubic feet. About a score of members of the Newcastle Association of Students of the Institute of Civil Engineers visited the partly-completed steel structure last week and were shown over it.

The South Metropolitan Gas Company's Bill came on Thursday and Friday before a Select Committee of the House of Commons, consisting of Sir Henry Fletcher (chairman), Mr. Strachey, Mr. Morris, and Mr. Tomkinson. The object of the Bill is "to empower the South Metropolitan Gas Company to raise additional capital; to purchase by agreement so much of the southern portion of the undertaking of the Gas Light and Coke Company as is situate in the County of London south of the Thames;" and to carry out other purposes.

The competing Bills of the Caledonian Electric Power Company and of the Clyde Valley Electrical Power Company, asking parliamentary sanction to provide electrical energy over extensive areas in the West of Scotland, and the petitions against the Bills of Govan, Greenock, and many other burghs whose areas these companies propose to invade, have, after ten days' hearing by a Select Committee of the House of Commons, been decided upon. The Caledonian Bill was rejected. The Clyde Valley was passed, but Port-Glasgow, Govan, Partick, Paisley, and Hamilton were struck out.

On Monday last the Select Committee of the House of Commons, presided over by Sir H. Fletcher, decided that the preamble of the Bill for transferring to the South Metropolitan Company the works of the Gas Light and Coke Company south of the Thames was proved, and suggested that the £900,000 to be paid to the latter company should be applied to the reduction of price to the consumers.

The hearing of the Mond Gas Bill was concluded last Monday by Colonel Welby's Select Committee of the House of Commons. In giving the decision of the Committee, the Chairman said the Committee considered, in addition to those points which had been promised by counsel for the promoters, they wished to make one more, which was that in the case of a new development of the gas, it must be certificated by the Board of Trade. Of the shares which had been allotted to Dr. Mond, 40,000 were to rank for dividend after other shareholders, and 35,000 after the holders of other shares had received 5 per cent. per annum. Subject to those conditions, he declared the preamble of the Bill passed, and ordered to be reported to the House for third reading.

The wonderful electric lighting effects in the great "Cinderella" pantomime at the London Hippodrome, which were carried out in such a successful manner on the "E. L. B." system, are now being repeated for various purposes in different parts of the country. Thus the entire Irish Section of the International Exhibition at Glasgow has been decorated by a scheme of garlands interspersed with shamrocks provided by the Electric Lighting Boards Company, of 7, Pall Mall. Again, we find a similar scheme of decorative illumination installed for the *café chantant* at the Crystal Palace, whilst the effects have also been used for decorative purposes on several occasions at the Grafton Galleries. The Hippodrome installation has, in fact, been quite a pioneer in the greater elaboration of electrical effects as now so easily obtainable on the "E. L. B." system.

In the House of Commons last week, the Omagh Gas Bill (Lords) came up for the second reading stage. Sir Walter Foster said he wished to see no step taken by the House which would prevent the Local Authority from acquiring under the Local Government Act powers of lighting on reasonable terms. Sir James Haslett, who supported the second reading, said the seconder of the rejection of the Bill (Mr. O'Doherty) had argued that if it were passed, the Local Authority would be deprived of the right of dealing with the property of the Gas Company, which was now to be put at a statutory value of £15,000, and the hon. member argued that if the property were left to an arbitrator to deal with he would pile up the value much more. The opponents of the Bill wanted to buy up the property of the Gas Company and assess it as it stood at present, and deal with it as a going concern. It was objected that the price of gas was now 5s. in Omagh, while it was only 3s. 6d. in Londonderry.

GENERAL.

The Durham City Council has decided to construct an underground lavatory.

The Northumberland County Council has decided to erect an isolation hospital at a cost of £1000.

The London County Council has agreed to lend the Woolwich Borough Council £2170 for the erection of a library.

The Nottingham Board of Guardians has decided to purchase a Green's steam economiser for the boilers at the new workhouse, at a cost of £800.

There was considerable activity in well-sinking in the Punjab during the past year, the total of 10,945 new wells being probably the largest on record.

The public baths in Balaam-street, Plaistow, were opened by the Mayor of West Ham on Saturday week. The buildings, exclusive of furnishing, cost £22,308.

The Liverpool Tramways Committee has decided to apply to the Board of Trade for sanction to borrow £319,000 for the purpose of carrying out the works authorised by the Liverpool Corporation Tramways Extension Orders, 1898 and 1900.

The tender of Messrs. Meldrum Bros., Limited, for their "Simplex" destructor and power plant to be erected at the pumping station, Sheerness, has been accepted.

The Local Government Board has sanctioned the necessary loan for the erection of an eight-cell Meldrum "Simplex" destructor and power plant at Walker-on-Tyne.

The Keighley and District Hospital has been presented with a thousand guineas by the daughters of the late Mr. R. L. Hattersley, Springfield, Keighley, in memory of their father.

The Middlesbrough Sanitary Committee has decided to appoint a female Inspector, part of whose duties will be to visit the poorer parts of the town and instruct parents as to the treatment of children.

At a meeting of the Loughborough Town Council, it was decided to make an application to the Local Government Board for sanction to a loan for the purpose of street works and the erection of a sanitary depôt.

A Local Government Board inquiry has been held at Market Harborough into the Urban District Council's application for a loan of £3050, to make a proposed new street from Fairfield-road to High-street.

The Bexhill Urban District Council has just taken a lease of Egerton Park, of fifteen acres, close to the seashore, which will be named Victoria Park, as a memorial to the late Queen, and thrown open to the public.

The inauguration of an electric enterprise of great importance to the county of Durham took place at Gateshead last week, when the combined new electric tramway and electric power services in that town were formally opened.

Last Monday, while a workman was clearing out a drain in Scotland-street, Glasgow, he was overcome by gas fumes, and a carter who went down to his rescue also became unconscious. Two workmen, who were passing, attempted a rescue, and brought the carter to the surface. The first man who was overcome by the fumes was, however, found to be dead.

We learn that considerable uneasiness is being felt in Belfast owing to an outbreak of small-pox which has taken place in the Oldpark district. During the past few weeks four patients, including two soldiers, have been treated in hospital, one case having terminated fatally. Two persons suspected of having contracted the disease have this week been removed to the isolation ward of the hospital.

The Board of Trade has recently confirmed Light Railway Orders authorising:—(1) The construction of light railways from Ravensthorpe to Cleckheaton, in the West Riding of the county of York; (2) the construction of light railways in the borough of Dewsbury, the urban districts of Cleckheaton, Liversedge, Heckmondwike, Gomersal, Birkenshaw, Hunsworth, and Thornhill, and (under certain conditions) in the city of Bradford and the borough of Batley, in the West Riding of the county of York; and (3) the construction of a light railway in the county of Warwick, in the urban district of Nuneaton and Chilvers Coton and the rural district of Atherstone.

A House of Commons Committee, presided over by Mr. Bill, has this week passed a measure introduced by the Corporation of Brighton, which contains some extremely interesting provisions. In the first place, it authorises the sale by the Brighton Aquarium Company to the Corporation of the whole of the company's undertaking for the sum of £30,000, and empowers the Corporation to construct and carry on a winter garden, pavilions, concert rooms, &c., as well as a school of marine biology, in connection with the Aquarium. Further, it empowers the Corporation to make a roof over the Aquarium, to be available as a promenade, and to admit the public thereto free of charge, and also to advertise the attractions of the Aquarium. Another provision of the Bill inflicts a penalty of 40s. on any manufacturer or dealer in "ice-cream, hokey-pokey, or other similar commodity" who permits such commodity to be sold or stored in any cellar or room in which there is an opening to a drain, or who, in the manufacture, sale, or storage of ice-cream, &c., does anything likely to expose it to infection or contamination. It is also provided that the Corporation shall keep a register of makers and dealers in ice-cream, &c., and that any unregistered person who deals in it within the borough renders himself liable to a penalty of £5 and a daily penalty of 40s.

The West Ham Corporation has in hand a scheme for erecting workmen's dwellings (double tenement) on the Manor-road and Temple Mills estates, which are estimated to cost £133,296. The rentals for the double tenements will range between 12s. and 12s. 9d. per week, and the houses will be fitted with all modern conveniences, including electric light.

Lord Overtoun, convener of the County of Dumbarton, opened last week the new joint hospital erected by the Western District Committee of the County Council of Dumbarton and Dumbarton Town Council. The hospital is situated on five acres of ground on the Cardross-road at Havock, which the two Authorities purchased for the purpose. It was estimated to cost about £14,000, but this sum is likely to be exceeded. The architect is Mr. J. M. Crawford, Dumbarton, and his plans were approved by the Local Government Board. The hospital contains six different buildings, consisting of administrative block, three pavilions of two wards each, caretaker's lodge, and other necessary buildings. The sewage will be treated by the septic tank system, which destroys all offensive and infectious matter. The whole of the buildings have been completed and furnished in the most scientific and up-to-date manner.

Mr. R. H. Bicknell, M.I.C.E., one of the Local Government Board's Inspectors, held an inquiry at Ilkley last Thursday into an application by the District Council for power to borrow money to reconstruct the bridges and culverts destroyed by the flood of last July. The expenditure which will be involved is estimated at £3550, but the Council also submitted for approval plans of a steel girder bridge, to be erected at the entrance to Heber's Ghyll, as an alternative scheme to the erection of a stone bridge, as recommended by their engineer, and it was calculated that a steel bridge will involve the expenditure of an additional £200. The Council decided to communicate with the Local Government Board in the course of a few days as to the scheme it wishes to submit for approval. There was no opposition. Mr. Frank Hall (Clerk to the Council), in his evidence in support of the application, stated that £7900 would cover all expenditure in repairing the damage caused by the flood. This sum was originally estimated.

The Middlesbrough Corporation having adopted its scheme of barging refuse out to sea stands in some danger of coming into conflict with the Redcar Urban District Council, if what the Inspector reported to the Sanitary Committee of that Authority is correct. He has reported that some time ago a quantity of refuse was washed up on the sands owing to the very high tides which prevailed about the time, and that the refuse was undoubtedly that which had been taken out to sea by the Middlesbrough Corporation. This is a serious state of affairs, and not to be tolerated if it is proved true. Redcar is a fashionable seaside resort, which is becoming more and more popular every year with people from the Midlands and the North of England, and the sands are the glory of the place. They afford a splendid recreation ground for the children, but if they once become the deposit bed of rubbish of the nature which is taken out to sea from Middlesbrough, then a serious injury is certain to be inflicted on Redcar.

Dr. E. Gwynn, Medical Officer of Health for Hampstead, has presented a report to the Hampstead Borough Council, urging in the strongest terms the necessity for making a collection of dust and house refuse twice a week during the summer months instead of once a week. He states that there are 152 blocks of flats in the borough, in which the refuse is generally stored in the well-like court-yard. The effluvium rises from the refuse and passes into the bedrooms. From all hospitals, institutions, and schools the refuse should be removed frequently. A short time ago a case came under his notice of a large school, in which an outbreak of diphtheria occurred, where the dust-bin was in the proximity of the children's playground. He appends to the report a list of flats, tenement and registered houses, and public institutions, numbering 2970, from which he considered that a collection should be made twice a week, and expresses the opinion that it would be well for the Council to go a step further, and consider the advisability of undertaking a twice-a-week collection for the whole borough—a question which will have to be considered in the near future.

The London and North-Western Company has ballasted the whole of its main line from London to Carlisle with clean granite chippings, which contain not a particle of dust; and it is stated that in consequence the traveller from London to Scotland, or *vice versâ*, may now leave windows and ventilators wide open, and enjoy the blessings of fresh air with no greater risk of annoyance from dust than if he were crossing a grass meadow. This is good, but there are other evils than dust met with in railway travelling. Cannot the London and South-Western do something to shut out the vile smells its travellers experience when passing between Earlsfield and Wimbledon?

The Lord Lieutenant of Ireland, speaking in Dublin on Saturday at a meeting of the local branch of the National Association for the Prevention of Tuberculosis, said he was gratified to hear that this disease could be treated successfully in Ireland. The condition of the tenement houses in Dublin, and the overcrowding of dwellings, rendered it extremely difficult for the people to obtain the fresh air which was so necessary for the cure of the disease, and he believed the present condition of sanitation in Dublin and Ireland required the gravest consideration. He hoped that the Congress to be held in London under the presidency of the King would be attended by the leaders of scientific thought in Ireland, and that its results would spread across the Channel and help to promote the health of Dublin.

PERSONAL.

Mr. F. E. Farrington, of Anston, near Sheffield, has been appointed Surveyor for Arundel.

Mr. Peirce, the Muncipal Engineer of Penang, has been appointed Municipal Engineer of Singapore.

Dr. Killam Roberts has been reappointed Medical Officer of Health for the rural district of Amptbill.

Dr. Gardner has been reappointed Medical Officer of Health for Kirbymoorside for the next three years.

Mr. Chas. T. Bacon, of Harlesden, has been appointed Sanitary Inspector to the Islington Borough Council.

The salary of Mr. Cook, Inspector of Meat, Fruit, Cowsheds, &c., has been increased from £200 to £225 per annum.

The Local Government Board has approved the appointment of Dr. T. Bamford as Medical Officer of Health for Uttoxeter.

Mr. H. E. Poole has been reappointed Surveyor and Sanitary Inspector for the urban district of Wath, at a salary of £150 per annum.

The Borough of Kensington has appointed Miss Grace Annie Looker as lady Sanitary Inspector at £110 a year. There were eleven applicants.

Dr. Charles Kelly has been reappointed Medical Officer of Health for the combined district of West Sussex for five years, subject to the sanction of the Local Government Board.

Mr. J. E. Harding, who for some time past has acted as Sanitary Inspector to the Hebburn District Council, has secured an appointment at Hetton-le-Hole as Surveyor and Inspector.

The Local Government Board has sanctioned the reappointment of Dr. M. A. Wood as Medical Officer of Health for the urban district of Ledbury, at a salary of £20 per annum.

Dr. Norman Moore has been elected the representative of the Royal College of Physicians of London in the General Medical Council of Education and Registration, in the place of Sir Dyce Duckworth, who has resigned.

We understand that Dr. F. J. Waldo, late Medical Officer of Health, St. George-the-Martyr, Southwark, is a candidate for the post of coroner to the City of London, vacant through the retirement of Mr. Langham. Combining as he does the joint qualifications of a medical man and a barrister-at-law, Dr. Waldo is essentially the man for the post. It will be remembered that Dr. Waldo was one of the selected candidates for the Medical Officership of the City, and was accorded a second place in the subsequent voting, but retired in favour of Dr. Collingridge.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2193.—FACTORY AND WORKSHOP ACTS: MODEL BYE-LAWS.—"Surveyor" writes:—"(1) I shall be glad if you will inform me whether there is a second edition published of Davies and Yabbicom's useful little book 'Notes on the Factory and Workshop Acts,' price 4d. (2) Would you let me know what bye-laws are included in Handford and Mackenzie's 'Model Bye-laws'?"

Answer. (1) A second edition of the book referred to has not been published. (2) Handford and Mackenzie's "Model Bye-laws," two volumes, price 25s., contains practically the whole of the bye-laws and regulations which may be made by a Local Authority under the Public Health Acts. The list is too long to be reproduced here. The book may be obtained from the office of this journal post free at the published price.

2194.—FEMALE SANITARY INSPECTORSHIPS: HOW TO QUALIFY FOR.—"K. B." writes:—"Will you kindly advise me how I should qualify for the post of (woman) Sanitary Inspector, where I should train, what examination I should require to pass, and what books on the subject would be most useful?"

Answer.—The querist should obtain by examination the certificate of the Sanitary Institute for Sanitary Inspectors. She may obtain tuition by correspondence through the post from some one of the gentlemen who advertise in our pages to prepare candidates for the examination. The books recommended are Reid's "Practical Sanitation," price 6s.; Model Answers to Questions set at the Sanitary Institute Examinations, price 2s. 2d.; Chapman's "Student's Guide to Success in Sanitary Inspector's Examinations," price 1s. 8d.; Taylor's "Sanitary Inspector's Handbook," price 5s. Any of the books may be obtained from the office of this journal post free at the prices named.

2195.—FACTORY INSPECTORSHIP: EXAMINATION BOOKS.—"Constant Reader" writes:—"Would you kindly recommend me a list of books to study for the examination for Factory Inspectors?"

Answer.—The querist is advised to refer to our answers to query No. 994 in our issue of March 18th, 1898, and query No. 485 in our issue of May 26th, 1899, which give extended information as to the syllabus of subjects for the examinations and the procedure. The querist will find, we think, that no special books are required in preparing for the examination.

2196.—HOUSES WITHOUT SANITARY CONVENIENCES: PROCEDURE.—"W. E." writes:—"I made an application to the Petty Sessional Court recently for closing orders under Sec. 32 of the Housing of the Working Classes Act, 1890, in respect to some houses which were in a fair condition, but had no proper privy and ashpit. The magistrates refused to issue an order, contending that they were in a sanitary condition, and that there being no ashpit and privy did not constitute them insanitary. Are the magistrates, in your opinion, acting according to law in dismissing the cases? If so, will you please inform me under what Act should proceedings be taken in similar cases?"

Answer.—Upon the facts stated the magistrates were, in our opinion, justified in declining to issue a closing order in regard to the dwellings. The Local Authority are enabled by notice under Sec. 36 of the Public Health Act, 1875, to require the owner of the houses to provide a sufficient privy, or w.c., and an ashpit, and on his default in providing them, may do the work themselves, and recover the cost from him. The Local Authority should proceed under this section.

2197.—SALE OF FOOD AND DRUGS ACT, 1899: TAKING SAMPLE IN COURSE OF DELIVERY OR TRANSIT.—"H. C. G." writes:—"What is the proper procedure on taking samples of milk on delivery according to the Sale of Food and Drugs Act, 1899? There does not appear to be any provision for a third part in case of dispute. Section 22 seems to imply that such is not necessary, but that the production by the defendant of a certificate of analysis in the proper form from a public analyst would be accepted as evidence instead of the usual reference to Somerset House. I should be glad if you will let me know if this is the correct view. Also, is it necessary to first obtain the consent of the consignee before taking samples of milk on delivery, or does such consent have to be obtained only in the case of taking samples on delivery of other articles of food?"

Answer.—The provisions of Section 10 of the Sale of Food and Drugs Act, 1899, are in extension of Sec. 3 of the Sale of Food and Drugs Act Amendment Act, 1879. In the earlier Act no provision was made for a portion of the sample to be sent to the consignor, but under Sec. 10 a portion must now be sent to him if his name and address appear on the can. There is no provision for a third part to be kept by the Inspector, but such may nevertheless be done as a matter of prudence. Sec. 22 of the Act of 1899 provides for a defendant obtaining an analysis and producing same in Court. This does not, however, remove the discretion of the justices to direct the sending of a sample to the Government Laboratory—see Sec. 21. It is not necessary to obtain the consent of the consignee before taking samples of milk on delivery.

STANLEY
Government Contractors.
Makers of Mathematical, Drawing and Surveying Instruments of every Description.
Gold Medals at the Great Exhibitions. Catalogues post free.
Address: W. F. STANLEY & CO., LTD.,
Great Turnstile, Holborn, London, W.C.

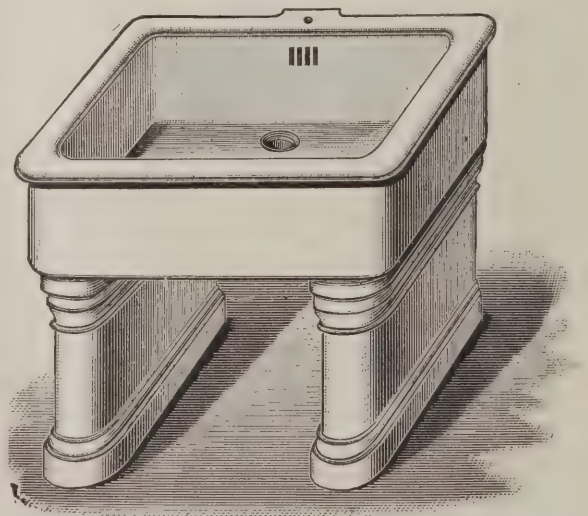
CRAIG'S WHITE GLAZED FIRE-CLAY SINKS
On White Glazed Fire-Clay Supports.
In appearance nearly equal to Porcelain, which they greatly excel in strength and durability. Admirably adapted for use in Kitchens, Sculleries, Butlers' Pantries, Laboratories, &c. Extensively used in houses of the better class, and in many important buildings throughout the country during the last thirty years.
Adopted by H. M. Board of Works, H.M. Commissioners of Prisons, &c.
Awarded First Prize Medal by the Sanitary Institute of Great Britain.



J. &. M CRAIG, Ltd., KILMARNOCK

THE PROGRESS IN PREVENTIVE MEDICINE.*

By Jas. T. Neech, L.R.C.P., D.P.H., Medical Officer of Health, Halifax.

Mr. President and Gentlemen,—I am afraid that I will not be able to present you with anything original this evening. But while original research and original investigation is absolutely necessary to the advancement of scientific medicine, yet sometimes the consideration of what is already known, the discussion, the criticism, the interchange of ideas upon what may be considered to be already established facts and principles, is calculated to broaden out and increase individual information, and promote a wider and more extended grasp of such subjects, and is, I think, equally necessary to secure true, reliable, and substantial progress in the theory and practice of our profession. It used to be said that the duty of a medical man was to cure disease, relieve pain, and prolong life. This definition I have no doubt pretty fully comprehended the scope of both our work and duty when it was enunciated; but to-day, in the light of modern progress, an addition must be made thereto, and it must read, "To prevent disease, to cure disease, to relieve pain, and prolong life," and undoubtedly it is preventive medicine which offers the widest field for future research and investigation and future progress.

The art of surgery has made great and rapid strides even within the recollection of many here present, so much so that only a comparatively small portion of the human body can now be held sacred and to be outside the reach of the surgeon's knife. It seems possible, therefore, that further advancement in surgery will partake more of the nature of improvements in methods and procedure. In medicine, too, there is no less marked advancement. Since the introduction of the microscope and the application of the more perfected methods of modern research the theory and practice of medicine has been completely modified. Some of the results of all this is that we have now a clearer idea and a more definite knowledge both regarding the nature and causes of diseased conditions generally. That so-called class of functional disease is being rapidly blotted out from our nomenclature. We now look upon unction as being the result of tissue change, or the occurrence of certain complex and complicated chemical, molecular, or other changes within the tissues, and I would further urge that the same specified function or act requires for its repetition the repetition of exactly the same or similar changes in the tissues. Hence it seems that alteration in function means a corresponding alteration in structure or in the quality of that sequence, or cycle of complex changes, of which function is the result. Also in the treatment of disease there has been a change. Drugs are not now looked upon as the active agents in the cure of disease such as they were in times gone by, and new systems and new methods have been adopted. Certain substances of an organic nature have been brought into requisition; for example, the thyroid extract in myxoedema and the various antitoxins for the treatment of the special disease for which each is applicable, and modern research in treatment is guiding itself in the direction of the latter method.

It is in preventive medicine, however, that perhaps the most marked progress has been made, especially during the closing years of the past century. There has been a vast quantity of invaluable statistics, vital and others, carefully compiled and tabulated from year to year, and the existence of such is very necessary to the advancement of public health. They frequently serve to point out to the investigator new paths of research, or direct his energies into those channels that are calculated to bring forth the most valuable results. Then, again, carefully and accurately compiled statistics, extending over a prolonged period, further serve to indicate the value or otherwise which new methods and new conditions, suggested by the advancement of scientific knowledge, and adopted and instituted from time to time, exert in the improvement of public health.

There has been a great deal of work done, and a large amount of information obtained, both with regard to the relation which the condition and surroundings of habitations bear to disease and the effects which occupation produce upon the health of those engaged in various manufacturing processes; with the result that there has been a marked improvement in the former, and in the latter improved methods have been enforced to minimise the danger.

Since the introduction of the germ theory and the acknowledged association of certain specific microbes with certain diseases in the relation of cause and effect, our ideas regarding the nature and propagation of zymotic diseases have completely changed. It is true that the specific microbe of several of the fevers have so far defied all the efforts that have been made to isolate them, at any rate with any degree of certainty, but that these diseases and others also are of microbic origin no one will now gainsay. Here, then, is a wide field for research, and one that is pregnant with possibilities, the attainment of which would be of the utmost value, because until each of these microbes has been discovered a ready method of detecting them made known, their life history worked out, and their possible relationship to other microbes, it seems to me that it will be impossible to decide when a person who has suffered from any of the infectious diseases becomes free from infection and is absolutely safe to mix with the public; and, further, it will be impossible to account for the origin of the many sporadic cases which crop up from time to time, and which appear at present to arise *de novo*. We do possess some little knowledge regarding the life-history of the typhoid microbe. It has been shown that it perishes when placed and is allowed to remain in virgin soil, but when it is placed in soil polluted with sewage, and to which additions of sewage matter are made from time to time, it will live, and possibly multiply.

We, at present, include under the term "typhoid" or "enteric fever," cases of continued fever which vary very much in their course, duration, and the symptoms manifested, so much so that I do not feel at all certain that all these cases are initiated and brought about by the action of one specific microbe. Hence it seems to me very necessary that the typhoid microbe should be further studied in its relation to others, and possibly to some of the microbes normally found in the intestinal canal, and whether the latter cannot under certain conditions take on a virulent form even allied to the typhoid bacillus.

When a man commences the work of emptying privies and privy middens, who previously had been unaccustomed to do so, or even when a fresh man is engaged at our Goux Yard in removing and renewing the tubs, after a varying period he becomes ill, and more or less feverish. I have, however, never been called upon to treat such a case, and cannot give the exact symptoms. This disease is, however, I believe, pretty well known among ashpit men, and I have heard it called by them "muck fever." Whether it is typhoid or not I cannot say.

I have necessarily only indicated a few of the directions in which sanitary science has made progress. Great advancement has been made all round, but as great as is the latter, I am sure one may venture to say that it is only the foretaste, only the stepping-stone to the accomplishment of still greater successes in the future, for I think that preventive medicine, above all other

* A paper read before the Halifax Medical Society, March 12th.

branches thereof, offers a far wider field for investigation and research, and holds in store vaster possibilities, the achievement of which will confer the greatest benefits, and bestow the greatest blessings upon humanity at large. In the prevention of zymotic diseases perhaps during recent years the line of investigation has been more definitely directed towards the discovery of methods for conferring the condition of immunity upon the individual. Just as certain persons are particularly prone to certain diseases, others enjoy a natural immunity. This, together with the fact that one attack confers upon the individual more or less freedom from future attacks, and the value of vaccination in the prevention of small-pox, which experience has shown, all naturally point to the possibility that some day we may be able to discover methods of conferring a condition of immunity in many other diseases.

A great many different theories have been put forward from time to time to explain the nature of immunity, but I imagine that it is due to no one thing or state of body, and that several factors co-operate in producing the condition. A few years ago the theory was enunciated that the white blood cells were the cause of immunity, and that they, and possibly also other cells of the body, play their part in producing the condition, cannot, I think, be denied, for the white blood cells have been observed to seize and destroy micro-organisms. Others, again, have urged that the fluids of the body have the power of destroying microbes, and there may be some truth in this also. But perhaps the more recent idea is that immunity is a vital act, that it is essentially due to the quality or condition or power, natural or acquired, of the vital activity of the tissue cells. Whatever life may be in its nature and its essence, it is at any rate a dynamic form of energy, and as such requires for its maintenance a constant tissue change, or a constant chemical, molecular, or other change within the tissues of an assimilative and dissimilative character; and doubtless there may be variation either in quality, intensity, or some other way in the character of these changes even in health, but if they are unduly interfered with there must be deviation from the condition of health. Now it is not merely in the presence of a pathogenic bacterium within the blood stream, or in any tissue specially liable to be attacked thereby, that danger lies, but in the poisonous substances given off or excreted as a result of the vital activities of these organisms, which, circulating in the blood, interfere with tissue change and vital action. I regard an attack of infectious disease somewhat in the light of the principle of the survival of the fittest, for in it you have life pitted against life, the vitality of the invading organisms pitted against the vitality of the tissue cells of their host, and the ultimate result seems to me to depend to a great extent upon the tenacity and duration with which the latter can resist the former and are able to carry out and perform their vital functions. After the attack is over the patient enjoys more or less immunity from the disease, because the tissues have become accustomed during the previous attack to the presence of certain toxines in the fluids from which they derive their nourishment, and have acquired the power of taking up nutriment and performing their function even in the presence of the poisons. It is a law in nature that an organism, at any rate within certain limits, can adapt itself to surrounding conditions. When the germs or microbes of a specific fever infect a subject who is immune thereto, the toxines they give off produce little or no deleterious effect upon the vital activity of his tissues, hence time and opportunity are given to the white blood corpuscles and possibly other cells to destroy them, and perhaps the emunctory organs to excrete them.

The term immunity is a relative one. There are degrees of immunity. There are individuals in whom a certain dose of a given poison would produce no effect, but give a larger dose or one more virulent in nature, and results follow characteristic of the particular disease. Also even in some mild cases of fever it seems possible for the patient to be re-infected with a fresh dose of the poison, or with one somewhat more virulent, and a relapse occurs. This I have several times seen in scarlet fever. Occasionally one sees a mild case of this fever brought into the wards with the characteristic rash and other symptoms; the disease runs its usual course and the temperature falls. But after the patient has been in hospital eight or ten days there is, perhaps, vomiting, the throat again becomes sore, the temperature goes up, and the rash re-appears; so that you have the rash out and desquamation going on at the same time—a distinct relapse. As far as I am aware, this is never seen in private practice—at any rate, I was not aware that it could happen until some time after I had charge of scarlet-fever wards.

Pigeons, hens, dogs, and frogs are immune to anthrax, but deprive pigeons of food, and they lose their immunity. The same thing occurs in the case of pigeons, hens, and dogs if they be deprived of water. Expose hens to cold to a sufficient extent to depress their temperature, and they lose their immunity to anthrax. Expose a frog to heat so that its temperature is raised, and it loses its immunity thereto also. Rats when fatigued are more liable to bacterial infection, and also animals bled to the extent of bringing on hydræmia. All these conditions interfere with nutrition and depress vitality, and, consequently, do they not point to the conclusion that immunity is largely and essentially a vital process?

It has been shown that immunity from certain diseases can be conferred upon animals and individuals, and I think there is no doubt but that the number of diseases in which it will be possible to do this will be increased in the future. It has also been shown that, under certain conditions, even natural immunity can be temporarily interfered with and its power suspended. It seems to me, therefore, not unreasonable to suppose that the converse may also be true, and that it may not be outside the bounds of possibility not only to establish a more or less permanent immunity in an increased number of diseases, but also to discover means whereby temporary immunity could be secured, and that such methods, under certain conditions, might be of great practical value.

COFFEE AS A DISINFECTANT.

The use of coffee as a disinfectant is generally known, but it is doubtful if the majority of people are aware of its true value in this direction. They probably know that it is handy and harmless, but besides possessing these qualities it is really one of the most powerful and effective agents known, as has been shown by repeated experiments. In one case a quantity of meat was placed in a close room and allowed to decompose. A chafing dish was then introduced and 500 grammes of coffee were thrown on the fire. In a few minutes the room had been entirely disinfected. In another room the fumes of sulphuretted hydrogen and ammonia were developed, and the smell—which no words can express—was destroyed in half a minute by the use of ninety grammes of coffee. As a proof that the noxious smells are really decomposed, and not merely overpowered by the fumes of coffee, it is stated that the first vapours of the coffee are not smelled at all, and are, therefore, chemically absorbed, while the other smells gradually diminish as the fumigation continues. The merest "pinch" of coffee is usually sufficient to cleanse a sick-room, even in aggravated cases. The best way to employ it is to freshly pound the coffee in a mortar, if no mill is at hand, and sprinkle it on a red-hot iron surface.—*Health.*

NUISANCES AND METHODS OF INSPECTION.[1]

By J. Spottiswoode Cameron, M.B., B.Sc., M.O.H. Leeds.

NUISANCES AND INSANITARY CONDITIONS.

(*Continued from page 426.*)

The amount of sunlight in the bedroom is an important factor in its healthiness. The windows should, therefore, be large. They should be capable of being opened. The nursery, if there be one, should be airy, and have plenty of sunlight. Fig. 14 shows the ordinary form of inspection chamber with trap.

Where there is no sewer, the house wastes may have to pass into a cesspool. The question of the dumb cesspool has again come into prominence through the abours of my namesake at Exeter. The dumb cess-

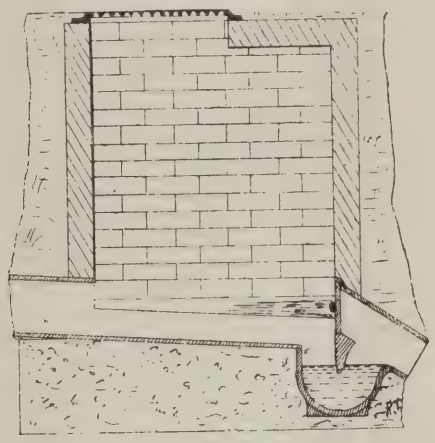


Fig. 14

pool is practically an intercepting tank, and the reason why it sometimes contains so little deposit is explained by the action of the anaërobic bacteria. They act best in the dark, and deprived of air. A cesspool on this type must be trapped at its inlet and its outlet, and it is better that the drain going to it should run for a short distance under a grate or in the open air. The effluent from the cesspool may be carried to the land, or to aërobic bacteria tanks, which should not discharge near to a dwelling-house or footway.

The yard should contain no pigstyes, hen-coops, or other nuisances near the house, and should be paved with a smooth, impervious material. The best form of ash-pit is a galvanised iron tub standing under a small pent-house. Dr. Quine's arrangement is, on the whole, a satisfactory one. We have tried it in ten cottages built by the Corporation, with good results. Where it is constructed without a cover, it is less satisfactory.

Where there is an inspection chamber (Fig. 14) and an intercepting trap it is possible to test the drains either by the smoke or water method. The simplest smoke process consists in putting one or two of Payne's rockets a few inches up the drain; and closing the end of the pipe with one of Addison's or Jones's plugs. One of the smoke producing machines may be used for the same purpose, connecting the tube of the machine with the tap provided for that purpose in the plug. The smoke should be allowed to continue till it is seen to escape from the ventilating pipe.

This should then be stopped and the process allowed to go on a little longer. It is almost necessary to have an assistant either to attend to this or to make a search for the smoke inside the house. This test, or the smell test already spoken of, has the advantage that the smoke or the smell will penetrate through leaky pipes within the dwelling. The water test is more satisfactory from a purely engineering point of view as it tests the outside drains their whole length to the inspection chamber. The plug having been inserted at the latter, the drains are filled with water up to the level of the surface of the lowest trap in or round the building. The level of the water at the surface is then noted and any fall observed. This is most conveniently done where there is a pipe without a trap, but, if the water in the trap be raised some inches above the water seal, any fall can be observed. If there is no fall it may be taken for granted that the pipes do not leak, but neither this test nor either of the others mentioned indicates absolutely whether or not the pipes are properly laid. If, however, a large quantity of foul matter escapes when the plug is withdrawn, it is probable that the drain, although tight, is badly laid. Had the drains been recently flushed there might be no indication of this kind.

On the whole the smoke test is fairly convenient, and its results when positive are of considerable value. The form I prefer, although it is a little inconvenient to carry, is the boxwood float with a spring. The spring is fastened down by a catch to which is attached a string. A small sealed glass tube containing calcium phosphide is inserted above the spring into two little wire loops. The string is wound round the ball, which is placed under the seal of the trap, and allowed to float on the water outside. The cistern is then discharged, or a pailful of water sent suddenly down the trap. The ball is carried over the nose beyond, and into the drain. The catch on the spring is loosened by the tension of the string. The powder is spread over the moist surface of the drain or soil-pipe and hydrogen phosphide liberated. This gas is very penetrating and easily recognised by its smell. Unfortunately it is somewhat poisonous.

The form of this test in the double tie tube is the one in more frequent use, chiefly on account of greater portability. There is a greater risk of some of the

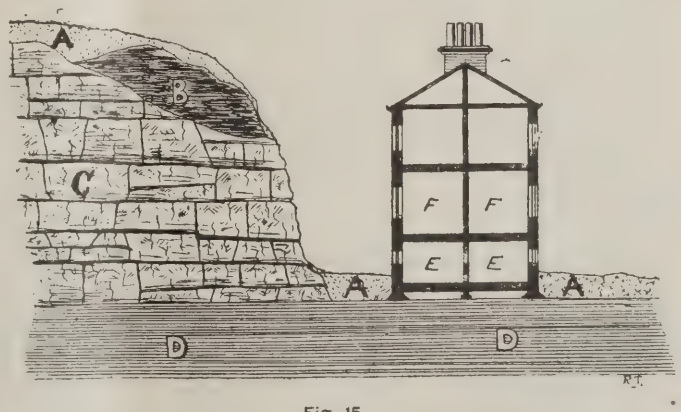

Fig. 15

powder getting loose and causing a smell the wrong side of the trap. Mr. Hammond has invented an ingenious variant of the method.

The closeness of surrounding properties interfering with light and air—the neighbourhood of pigstyes, privies, and other nuisances on adjoining properties—must all be observed in examining the outside of the house. The condition of the brickwork and of the roof,

[1] A lecture delivered in the Philosophical Hall, Leeds, April 13th, 1901. The illustrations to this lecture are from Dr. J. Spottiswoode Cameron's little work, entitled "Is my House Healthy?" published by Mr. R. Jackson, Leeds, and are reproduced in these columns by special permission

the situation of stacks of ventilating pipes in their relation to windows and chimneys (Fig. 13) will all be observed. The aspect of the house and the nature of the site must also be noted. A terrace of through houses is best placed when it runs north and south, as direct sunshine can, in that case, enter each side of the house at some portion of the day. A row of back-to-back houses, with similar bearings, will get the sun in fine weather either morning or evening on each house. A row of back-to-back houses running east and west will have the sun upon the south side, but only during a very small portion of the dog-days any upon the houses facing north, and what does reach them will do so very obliquely.

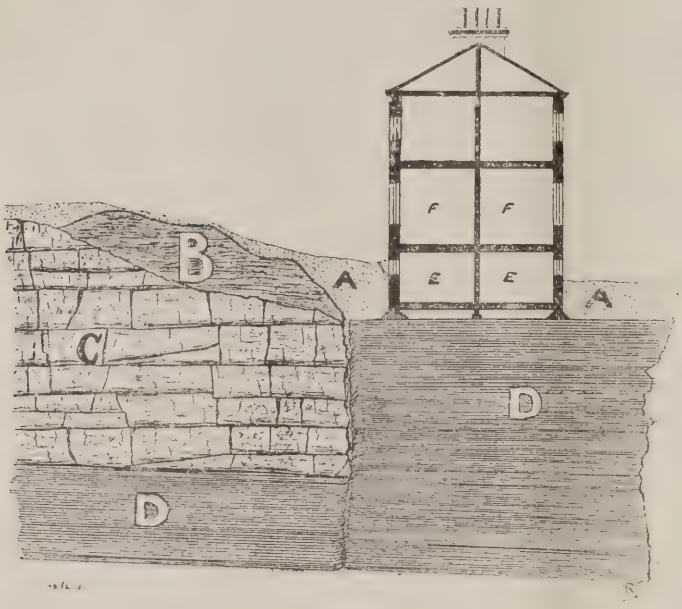

Fig. 16

I close with three slides showing how a house built in the neighbourhood of a geological fault may easily be damp. The first slide (Fig. 15) represents a house against a hill-side, evidently damp from the moisture exhaled from the rock behind, and from that which, percolating into the porous soil on which the house is built, is prevented from getting away by the denser stratum D below.

The next diagram shows the same house on the up-throw of a fault. The water falling on the hills behind, penetrating the porous strata C, rises along the line of the fault. The remaining diagram shows a house upon the down-throw of a fault, also made deep in a somewhat similar manner.

Finally, in your examination of a house, be systematic, be thorough, note down your findings at the time, and read through your notes before leaving the premises to make sure that you have left no part of the inspection half completed.

We find it convenient in Leeds to classify our house examinations under six groups. In three of these groups the examination is required to be complete of the whole premises from top to bottom, and these complete examinations are made (1) on account of the existence of infectious disease; (2) in consequence of complaint; (3) in pursuance of house-to-house work. It is obvious that if your house-to-house work is well in advance, the examinations under (1) and (2) can be made much more rapidly.

We have, however, three other groups of house inspections in which, generally on account of complaint made, and in order not to interfere with the more systematic examination house-to-house, the Inspector is permitted to make what is called a "partial examination." This may concern (4) the occupants. In this case he fills up house-to-house queries Nos. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, and 14. As this partial examination is generally in consequence of overcrowding, he is expected to give the dimensions of each room and the number and ages of its nightly occupants. Another partial examination may refer to (5) buildings and offices. In this case we expect house-to-house queries Nos. 1, 2, 3, 4, 5, 6, 7, 8, 11, 12, 13, 14, 15, 26, 27, 28, 29, 30 filled up, and any other necessary information given. Stress would, of course, be laid on the dryness of the house, the adequacy of the ventilation and the sufficiency of the closet accommodation Another partial examination permitted occasionally refers (6) to drainage. The queries to which answers must be given in every case are Nos. 1, 2, 3, 4, 5, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 30, and 32, along with any similar information. The drains should in this case be tested. These three partial examinations are expected to be, as far as they go, as systematic and complete as the whole house examinations described, but it is obviously preferable to make the examination complete at first.

So far I have spent much time in describing the examination of a house. I have not so much attempted to describe each particular fault, which might be found in a dwelling, as to indicate the methods which should be employed. While the house is the unit, and while it is desirable that every house in your district should be examined as completely and in some such method as that described, it is obvious that there must be, in addition, a more rapid inspection of the whole district for more obvious nuisances. It is well to map out your district, say, into five divisions, and to spend a

Fig. 17

portion of one day each week perambulating this division, spending, if possible, another portion of at least four days in the week in following up from house to house the complete examination of dwellings and their surroundings in a smaller portion of one of the larger divisions. In this way you will be able to carry out, at one and the same time, what one might distinguish as a cursory and a minute description of your district. Last, and perhaps really least in real importance, is the examination where complaint has been made. This cannot, of course, be neglected, and it is better where, say, illness is suspected to be due to insanitary conditions to let your examination of the house be on lines as complete as those I have already described.

It is not part of my subject to deal with the methods of abating nuisances. It is, however, part even of the Assistant Inspector's duty to ascertain that the required work has been carried out, and in the weekly perambulation of his district he should, of course, note what has been done and what has been left undone. If he be an Assistant Inspector he should keep himself informed as to when the notice went out and what period of time is allowed for its completion, and should report to his superior officer as soon as that time has expired. For this purpose it would be well if he were to enter in his diary beforehand the dates when such notices run out, and should make it in his way to visit as soon after that date as it is practicable. In this manner, as in the examination of the house itself, much time will be saved by a man who is systematic.

System, method, and tact will ensure in the examination of a house that the Inspector leaves no possible source of nuisance unquestioned, that in the examination of his district no obvious nuisance, such as the stoppage of street gullies, or accumulation of filth, is overlooked, and that the works which have been ordered at his instance are properly carried out. System, method, and tact, with a respectable knowledge of his work, are the essential qualities of a good Sanitary Inspector.

SANITARY WORK WITHIN THE ARMY.

By "Justice."

The history of sanitary work within the army is full of interest, as showing how a highly important element in army life, and of supreme importance to the well-being of the soldier serving England under very trying conditions over a wide-scattered empire, can be killed out and rendered useless by official prejudice or culpable neglect.

Up to 1855, the Crimean epoch, the prevention as opposed to the cure of disease formed no official part of the duties of the Army Medical Service.

Generation after generation of distinguished military surgeons had pointed out the need of studying this vital branch of army medical economy, but they were simply voices crying in the wilderness, and had no official authority to speak or to write one single word on these vital matters.

The soldiery died in a deplorable way from purely preventable disease, caused by easily removable conditions; and the theory of military officialdom was—doctors are very good in their place, but that place is the curing of the sick in the hospitals.

After the disasters of the Crimean campaign, and the great wakening up of the nation to the defects of its military system, a real step forward was taken in installing sanitary science as a factor in military efficiency. Sanitary rules were laid down, the surroundings of the soldier as to cubic space greatly improved, and a special sub-department formed in the Army Medical Department to act as an advisory and recording office on all army health matters.

The further to secure a supply of trained sanitary officials, the great Edmund Parkes was made Professor of Military Hygiene at the newly established Army Medical School, and with an assistant professor he organised the Netley teaching in hygiene, and the foundation of the Public Health Laboratory at Netley took place in due course.

A special order was issued by the War-office, conferring on Medical Officers the right and the duty of making sanitary recommendations to military commanding officers, and as a result in the succeeding years a real improvement took place in the sanitary condition of the soldiers. A succession of experienced and able officers of standing held the office of Sanitary Chief of the sub-department of the Army Medical Office and their reports in the annual Blue-books of the Army Medical Department were of real value, full of instructions to the officers, and with practical results to the men.

In carrying out their sanitary duties the Medical Officers constantly incurred great opposition and ignorant obstruction from those who knew nothing of their aims, and in many cases incurred great risk of personal ruin in the service for outspokenness in this important work.

The whole aim of the reactionary and more ignorant portion of the military officers was at all costs to kill out the sanitary initiative of the medical service, to drive these officers entirely to the care in hospital of men who should never have been sick, and at all costs to prevent the medical service in any way standing up for the soldiers' rights, in food, lodgment, or sanitary surroundings.

It was evident to them that whatever drew into the army medical service, an ignorant, idle, indifferently trained body of Medical Officers would in the end surely weaken the sanitary initiative of the medical service; and the parrot cry of "good doctors" in the curative sense, as opposed to far-seeing sanitary officials, became the watchword of a party in the army.

From the time of the necessary unification of the medical service, carried out in 1873, the whole of the feeling that that reform introduced into the army was made use of to crush out sanitary work.

By the abolition of the statistical branch of the medical office in 1881, a blow was given to the guiding and thinking power of the army medical office, and immediately after Lord Wolseley attacked the sanitary work of the doctors in his "Field Service Manual" put himself forward as the standard-bearer of the anti-sanitary party in the military body, and finally, before Lord Camperdown's Committee on the medical service in 1889, proposed the complete abolition of the army medical school, and all the sanitary training of the officers it implied.

It may safely be said that a more injurious blow was never given to the army, and this, too, by one who posed as an advanced soldier.

As Adjutant-General and Commander-in-Chief he was then able to put in force all his anti-sanitary views, and scores of commanding generals and subordinate officers, influenced by his position, his known proclivities and aversions, followed blindly his dangerous lead.

With logical sequence Lord Wolseley abolished the sanitary officers laid down by the post-Crimean reformers in 1858 for the divisions and the army corps in war; and, presumably owing to his influence, an untrained and unspecialised major in the R.A.M.C. sat for ten years in the chair of the Sanitary Chief of the Medical Branch of the War-office. That this officer had been the personal doctor of Lord Wolseley in the Nile expedition of 1855 may have been a mere coincidence, but the coincidence is peculiar and striking.

It may safely be said that for all the ten years of this sanitary control a period of absolute stagnation occurred in military sanitation, and every suggestion put forward by the Medical Officers for the soldiers fell unheeded to the ground.

Under Director-Generals chosen by influences, which it is difficult to describe, the whole sanitary initiative of the English army under the control of the War-office was practically in abeyance, and the English army, which in the 'fifties set the lead in sanitary reform, is to-day probably the most retrograde in Europe in its crowded barracks, defective bathing accommodation, and the want of suitable and warm clothing and underwear for the soldier. With a medical administration thus weakened and a sanitary branch practically in abeyance, the South African war broke out, and an army was sent to South Africa absolutely without a sanitary staff. The principal Medical Officers of divisions, themselves overwhelmed with work, were supposed to carry out this duty; and the principal sanitary officer of the army—an officer specially appointed by the Sydney Herbert School of reformers in 1858—had no place in the expedition. It seemed a complete return to Crimean days.

The deaths from enteric that have resulted are as surely the logical outcome of the destructive action of Lord Wolseley and the reactionary party in the army, and a weak medical directorate, as anything can possibly be.

As contributory details in this matter of the general breakdown of the sanitary side of army work, it is to be noted that while principal Medical Officers of districts in former times made their inspections of their district twice each year; now they do it once only, and they are practically unable to personally see the result of their suggestions for improvements for a whole year after they are made. The monthly sanitary report of former years has now been reduced to a quarterly report, and so on in every detail of sanitary supervision.

The post of Chief of the Sanitary Branch of the Army Medical Office at the War-office is to-day held by a major of the medical corps, whose experience of the army and of the empire must be naturally limited by want of higher rank and service.

The Blue-book of the Army Medical Service, once a publication of real sanitary value, and formerly presented by the State to every Medical Officer annually, is now a meagre publication, and is no longer so individually bestowed.

The sanitary officership at Aldershot camp, once held by a Medical Officer of colonel's rank, is now abolished, and it would be difficult in any single large garrison to say who is the responsible Medical Officer of Health. The whole aim seems to be to drive the doctors into the military hospitals, to treat soldiers who should never have been ailing at all had better lodgment, feeding, education, and employment been available for them. Recruiting is greatly handicapped by the existence in barracks of defective sanitary surroundings for the soldier, such as could be in a year or two remedied, if any real desire existed for reforms. No body of officers in the army know this better than the doctors, but the constant statement is made by them that, however idle, careless, or ignorant they may be, promotion may still come; but speak one word for sanitary reform, their future career is doubtful, and an ominous silence follows on all sanitary matters.

In no branch of their duties have the Medical Officers suffered such oppression and such official despotism as in their sanitary work. The whole aim of ignorant or reactionary officers in the service has been to cow and break down the efforts of the Medical Officer in his sanitary duties. Just as an ignorant or interested Vestry or Board of Guardians may bully their Medical Officer if he shows sanitary initiative, so in the military service ignorant or incapable generals may resent all sanitary recommendations made for the good of the soldiers by the medical service; and the future career of the Medical Officer may be marred by confidential reports made against him for work done for the good of the soldier and the State. In no part of their duties do the Medical Officers need more protection than in their sanitary work, and in none do they receive less sympathy or support.

THE SEWAGE DISPOSAL WORKS AT OSWESTRY.*

By G. William Lacy, Borough Engineer and Surveyor, Oswestry.

The bacterial sewage disposal works were designed and partly carried out by the author's predecessor (Mr. R. O. Wynne Roberts) and completed under the supervision of the author in June, 1899. They have been constructed by direct employment of labour, and the cost has been met out of current revenue.

Prior to the construction of these beds the system of treatment was crude, the sewage simply running through two settling tanks and away. In 1895 Messrs. John Taylor, Sons, and Santo Crimp, civil engineers, submitted a report on the question recommending a scheme which, including the purchase and laying out of 51 acres of land and works for dealing with the sludge, was estimated to cost £15,000, but on account of the cost this was not entertained. In October, 1896, the author's predecessor submitted a report, and finally it was decided to commence an experiment on the lines carried out by Mr. Dibdin at Sutton. This, after several months' trial, proving a success, it was decided to carry out a complete scheme, and the present works were commenced.

There are nine primary beds, the surface area of each being 60ft. by 60ft., and nine secondary beds, each with a surface area of 60ft. by 50ft., and they are constructed partly in the natural ground, and partly by earthen embankments, which are 11ft. wide at the bottom and 2ft. 6in. wide at the top. In the secondary bed embankments clay puddle was put as a security against percolation. On the floors of the beds lines of 3in. diameter agricultural pipes, a yard apart, are laid connecting with brick channels, which terminate in a small brick chamber in each bed, with the exception of the central ones, where they connect with a channel around the valve chambers. From these brick chambers 9in. glazed pipes are laid to the valve chambers, for discharging the effluents. The beds are filled with cinders, which were riddled from an old and large accumulation of house refuse; the gauge of those in the primary beds being from $\frac{3}{8}$in. to $1\frac{1}{2}$in., though containing very little of the larger size, and in the secondary beds from $\frac{3}{8}$in. to 1in. The depth of the cinders is 4ft. 6in. in each series. In the centre of each series there are automatic valves, which were designed by Mr. Wynne Roberts, in conjunction with Mr. Henry Roberts, Water Inspector, worked by water pressure from the town mains, which distribute the sewage and primary effluent to the various beds in rotation, hold up the sewage, &c., in contact in the beds, and discharge the effluents in due course.

Since the completion of the beds, it has been found necessary to put in aëration pipes from the ends of the collecting channels to the surface, in order to facilitate the discharge and complete drainage of the contents of the beds, and this has had a beneficial effect.

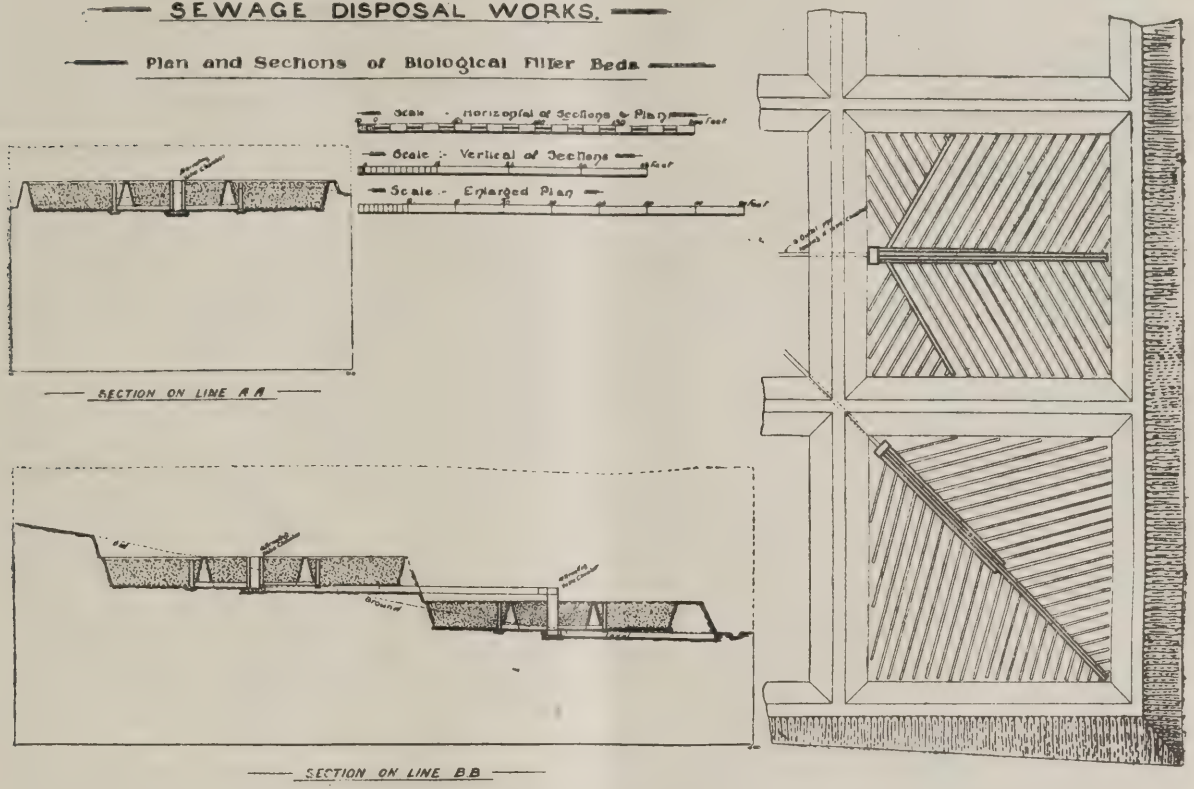
The primary beds have since the commencement of their full use been reduced in capacity by about 30 per cent., but no further decrease has been observed for some time; if anything, since the aëration pipes referred to have been fixed the capacity has increased, and certainly the results have been somewhat better

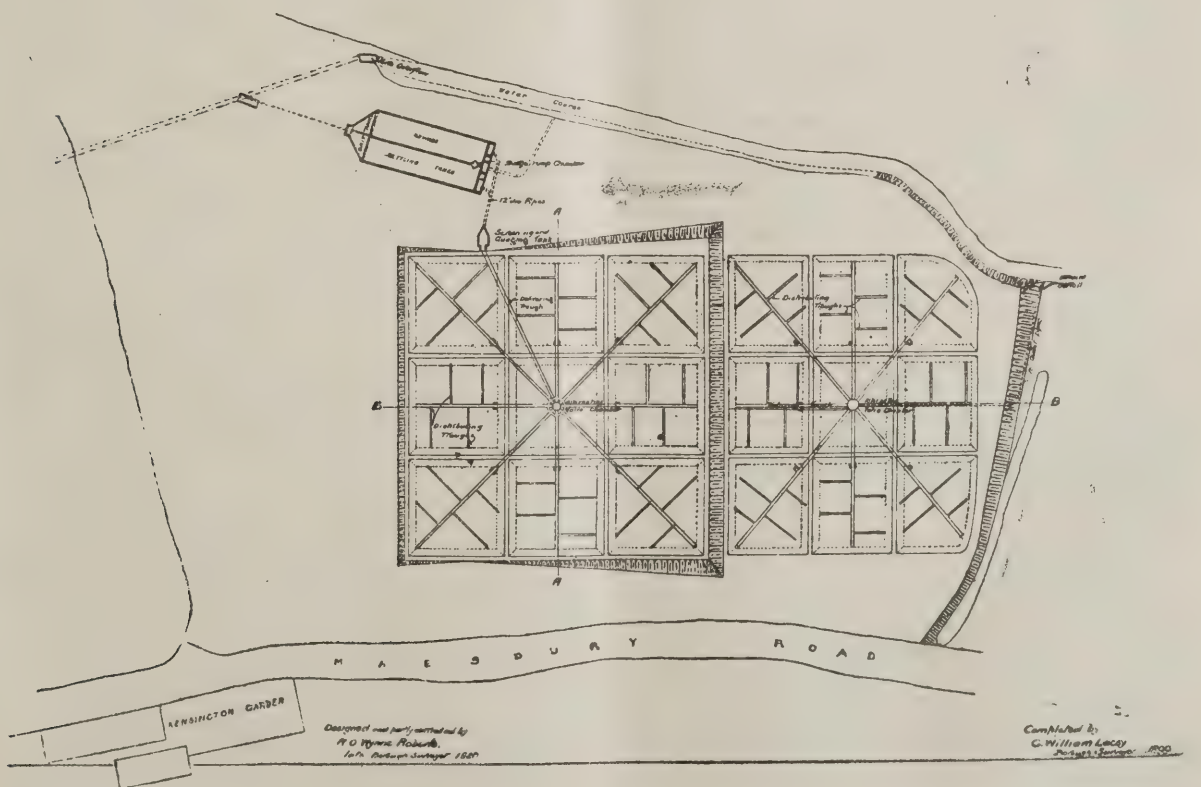
* From a paper on "Oswestry Municipal Work and Progress," read before the Incorporated Association of Municipal and County Engineers at Oswestry, May 18th, 1901.

BOROUGH OF OSWESTRY

SEWAGE DISPOSAL WORKS.

Plan and Sections of Biological Filter Beds





than before. No appreciable decrease has taken place in the capacity of the secondary beds.

The sewage first of all passes through one or both of the two settling tanks, 70ft. by 15ft. by 4ft. 6in., and in these a considerable quantity of sludge precipitates, no chemicals being used. The sewage and primary effluent are distributed over the beds by means of wood troughs, and the final effluent passes away through 12in. diameter pipes and discharges into a small water-course.

The sludge from the settling tanks is pumped out at intervals of from eight to ten weeks, mixed by machinery with fine screened ashes, and finds a ready sale to farmers at 6d. per load. It is not contended that this part of the process is ideal, or one which it is desirable to continue; but at the present time it serves to dispose of the large accumulation of screened ashes (the fine residue from the riddling), which otherwise would be more or less somewhat of a white, or rather, in this case, a black elephant. The author, some time ago, recommended his Sanitary Committee to consider the advisability of adding septic tanks, and in all probability this may eventually come to pass.

The quantity of sewage dealt with in the course of a year is about 160,000,000 gallons, the average daily flow in 1900 being 440,000 gallons, and the dry-weather flow 387,000. This includes a considerable quantity of spring or surface water which finds its way at some points into the sewers, as otherwise the dry-weather flow should not be more than 250,000 gallons per day. Notwithstanding this dilution the sewage, as the analyses show, is very strong, containing as it does a considerable proportion of brewery, tannery, and fellmongers' refuse.

The occasional analyses made of the effluent from the primary beds go to show that a remarkable proportion of the purification is effected by the first contact.

Samples of the effluents which have been kept for longer than a year show no signs whatever of putrescence, and analyses made during very severe winter weather showed but a slight diminution in the degree of purification. This diminution is but natural, as when the beds are partially covered with a sheet of frozen snow, the admission of air into the beds must of necessity be retarded; but this lessening of aëration is not likely to be of sufficient duration to materially affect the results. Records of temperatures taken during severe weather showed that not only the sewage, but the interior of the beds, both when full and empty, were several degrees above freezing point.

The cost of the construction of the bacteria beds and other work in connection therewith has been slightly over £2000, or equal to the sum of 4s. per head of population.

The net cost of maintenance at the present time, including sludge disposal, is about £225 per annum, or equal to 5¼d. per head of population. It is expected that this cost will be materially reduced ere long, as the automatic valves are being improved so as to render them more dependable, as up to the present it has been necessary to have a man on the works during the night.

As before stated, the cost of the construction of the works was defrayed out of revenue, but not the cost of the land acquired, and on June 2nd, 1899, a Local Government Board inquiry was held, sanction being sought to borrow the sum of £3500 to cover the above and other additional expenditure. This was not obtained, as our works did not allow for dealing altogether with six times the normal flow of sewage, and for after treatment of the effluent on land. This result, however, knowing the attitude of the Local Government Board on the subject, was no more than need have been expected.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

METROPOLITAN BRANCH.

A MEETING of members of the Metropolitan Branch of the Incorporated Society of Medical Officers of Health was held on Friday at the Royal Statistical Society's rooms, Adelphi-terrace, W.C. Dr. F. J. Allan, president of the branch, occupied the chair, and there was a good attendance.

PLAGUE PRECAUTIONS.

A circular from the Public Health Committee of the London County Council respecting plague precautions was submitted, and considerable discussion took place as to its administrative aspects. It was held that sufficient arrangement for notifying borough Medical Officers of Health had not been made.

Dr. WINTER BLYTH, M.D., moved that representations be made to the Local Government Board on the subject, calling attention to the fact that present arrangements in regard to plague precautions in London did not provide for the borough Medical Officers of Health receiving early information from the London County Council as to suspected cases. He contended that in a matter of this importance to the community at large it was as needful for Medical Officers to receive this information at once as the Medical Officer's department of the London County Council.

Dr. F. J. SYKES seconded the motion, which was agreed to *nem. con.*, and the honorary secretary, Dr. O Field, was requested to take the necessary steps for laying the views of the Society before the Local Government Board.

SUPERVISION OF DRAINAGE WORK.

Dr. J. PRIESTLEY (Lambeth), in accordance with notice, drew attention to a circular letter recently sent to the metropolitan Borough Councils by the Royal Institute of British Architects on the subject of the inspection and supervision of drainage works, and moved:—"That, in the interests of efficient administration, all drainage work, whether of old or of new buildings, should be under one department of a Sanitary Authority, and that department should be the Sanitary Inspector's." He said that he regarded this question of the control and supervision of drainage works as very important in connection with the administration of the Borough Councils, and in support of this view he had collected some useful statistics which ought to be placed on record. It would be noted that the Royal Institute of British Architects went as far as possible in suggesting that the sanitary fittings and drainage arrangements of old and new buildings should be placed under the Surveyor's or Engineer's department. Reasons for this alteration were not given, but the outcome of such a drastic change would be a large increase in the staffs of the Surveyor's department, and a diminution of the inspectorial staffs, which were fully qualified to carry out this particular work. Sanitary Inspectors had a better knowledge of sanitary and drainage appliances than foremen and clerks of works, or assistants in the Surveyor's department. At least this was the case with metropolitan Inspectors, who had to pass a special examination to qualify them for their office. It therefore followed that the public health departments of the new Borough Council should have the control of all drainage work. In some cases in past years the drainage of new buildings was left to the Surveyor's department, and the drainage of old buildings with the sanitary staff. This caused dual control, and very often friction between the two departments. The sanitary arrangements in new buildings would be passed by the Surveyor's department, and sooner or later, if a case of infectious disease occurred, the Sanitary Inspectors would serve notices

for compliance with some drainage bye-law founded on modern principles. Thus owners of property would be put to much unnecessary trouble and expense. He thought it was desirable that the drainage of new buildings should be under the control of the officers who had the supervision of the drainage of old buildings. There were obvious advantages in consolidating the administrative work so far as sanitary arrangements were concerned under one set of officers. It was clear that the Medical Officer's department was better fitted in every way to deal with the drainage and sanitary fittings of all buildings. If the idea of the Royal Institute of British Architects was carried out, then the Sanitary Officers would have to supervise and test the work carried out by the Surveyor's department, the result of which would not always conduce to harmonious staff working. Besides, there would be involved a large increase in the Surveyor's staff, and this would be contrasted with the present tendency to increase the inspectorial staff of the Public Health departments. The Acts of Parliament dealing with drainage work as related to London left the control with the sanitary staffs, and any certificates were only given by the sanitary officers. The following statistics were important :—

Supervision and Control of House Drainage.

New building.	Old buildings.	
12	2	Under Surveyor's staff
16	23	Under Sanitary Inspectors
0	3	Under both Surveyor's staff and Sanitary Inspectors
2	2	Under Sanitary Inspectors acting under Surveyor
10	18	Sanitary Inspectors acting under Medical Officer
4	5	Sanitary Inspectors acting under both Surveyor and Medical Officer

Only two Borough Councils had arranged for the drains of both old and new buildings to be under the control and supervision of Surveyor's department, viz, Holborn and Kensington.

Drains of new buildings under supervision	..	Surveyor's staff ..	12
	..	Sanitary Inspectors	16
Drains of older buildings under supervision	..	Surveyor's staff ..	2
	..	SanitaryInspectors	26
Drains under supervision of Surveyor's staff	..	New buildings ..	12
	..	Old buildings	2
	..	New and old buildings	2
Drains under supervision of Sanitary Inspectors	..	New buildings ..	16
	..	Old buildings	26
	..	New and old buildings	16

Sanitary Inspectors Act in regard to drainage work under :

Surveyor alone	New buildings 2,	old buildings, 2
Medical Officer alone ..	,, 10,	,, 18
Both Surveyor and Medical Officer ..	,, 4,	,, 5

He regarded these statistics as of importance; they had been collected from the Borough Councils, and the object of the motion was to counteract the effect of the circular sent out by the Royal Institute of British Architects.

Dr. Sykes seconded the motion for the purposes of discussion, but said that he could not agree with it in its suggested form. It was impossible to keep engineers or surveyors entirely out of drainage work. In his district he had practical control. The motion was too sweeping, and he hoped it would be modified in some way.

Dr. Winter Blyth pointed out that the Surveyor's departments often had to open up drains for the sanitary staff and supervise the connections.

The Chairman asked what action had been taken on the circular. In the case of his Council at Westminster, it had been ordered to lie on the table. In that borough the Sanitary Inspectors were solely under him.

Dr. Priestley said that three Authorities—Holborn, Kensington, and Islington—had agreed with the circular; five had disagreed with it, viz., Bermondsey, Battersea, Woolwich, St. Pancras, and Shoreditch, while eighteen had decided to take no action; two Authorities—Wandsworth and Stoke Newington—had not yet sent in returns.

Dr. L. Parkes asked if it were wise to pass any resolution. Circumstances in the various boroughs widely differed, and a general rule was difficult of application.

After further discussion, it was resolved to modify the resolution to the following : "That in the opinion of this branch, all plans of drainage should be submitted to the Medical Officer and be signed by him before being submitted to the Surveyor," and in that form was agreed to with one dissentient. It was resolved that a copy of the resolution should be sent to the Medical Officers of Health of the various metropolitan Borough Councils.

BACTERIOLOGY OF VACCINIA.

Dr. R. A. Farrar, M.A., M.D., gave a valuable paper on "The Present Condition of our Knowledge of the Bacteriology of Variola and Vaccinia," and the speakers included Professor Dr. Tavel, of Berlin. A hearty vote of thanks was accorded to Dr. Farrar for his address.

PAISLEY'S NEW REFUSE DESTRUCTOR.

The new refuse destructor for Paisley, which has been erected by the Burgh Corporation at Underwood, was formally opened last week. Provost Wilson performed the opening ceremony, which was attended by a large number of representative gentlemen. Previous to formally opening the destructor the company were shown over the building, and the destructor was put in operation, so as to show the system followed in the destroying of the town's refuse. The Provost then declared the destructor open, after which the company adjourned to the large office attached to the works, where luncheon was served.

Provost Wilson, in opening the proceedings, referred at some length to the work of the Public Health Committee since that department took over the cleansing of the town twenty-five years ago. Formerly it had been the practice to dispose of the unsaleable portion of the town's refuse in public coups. That system, however, was not conducive to the health of the town, and so the Commissioners were brought face to face with the question of destroyng the refuse by fire, which was the surest and safest way of dealing with such rubbish from the public health point of view. But it took a number of years before the Council could be got to appreciate the necessity of getting rid of the refuse by burning, and it was not until April, 1898, that a Committee was appointed to inquire and report regarding these destructors. That Committee inspected many destructors in Scotland and England, and as the result of their investigations they recommended the adoption of the Horsfall system for Paisley—that which they had now inaugurated. The destructor had fully come up to their expectations. At present they were sending only about 60 tons per day to it; but he had it on reliable authority that it could easily dispose of 100 tons per day. There had been considerable agitation in the minds of the people regarding the alleged nuisance which the destructor would form in the district in which it had been erected; but now that the works had been seen in operation he thought every one would be satisfied that there had been no reason for such apprehension. There had been a good deal of expense in connection with the erection of the works, and it might be asked what they were going to get in return

for that expenditure. He would only answer that in destroying the refuse the destructor would have a powerful influence in increasing the cleanliness of the town, and it would doubtless also assist them in removing that blot which rested on Paisley of having the highest number of enteric fever cases of any of the principal towns of Scotland.

Councillor GLOVER, as convenor of the Public Health Committee, then gave some interesting particulars regarding the progress made within the past few years in the sanitary work of the town, and characterised the new destructor as one of the best investments they had yet made on behalf of the public health of the community.

Bailie BROWN afterwards proposed "The Contractors," which was acknowledged by Mr. G. WATSON and Mr. MORTON, and in their reply Mr. Watson presented the Provost with a silver tray as a memento of the occasion, and Mr. Morton presented Councillor Glover with a silver cigar case.

REVIEWS.

The Burials Act, 1900; *with Notes and Index*. By JAS. BROOKE LITTLE, B.A., Barrister-at-Law. Shaw and Sons. Price 7s. 6d.

THE editor of this little volume is a well-known authority on the law of burial, and the publication comes most timely. The Burial Act of 1900 has effected very important changes in the law, which require immediate attention from public Authorities. These changes, and the difficulties of construction in the new Act, are set forth and ably discussed in copious annotations. The Burial Act, 1900, we may observe, removes the obligation which was formerly incumbent upon Burial Boards to consecrate a portion of a cemetery, and also that which imposed upon them the duty of building a chapel upon a consecrated part of the cemetery. Every Burial Authority is now required by this Act to submit to the Secretary of State a table of fees to be received by them in respect of services rendered by any minister of religion or sexton, and such fees are to be recovered by the Burial Authority and paid over to the minister or sexton. Prior to the passing of the Act the Authority were under no obligation to collect such fees, and Nonconformist ministers had no statutory right to demand any fees whatever for performing a burial service in a burial ground. Now, however, he can recover his fee by action against the Burial Board. Sub-sections 4 and 5, of Section 3 of the Act, which provide for compensation to incumbents and sextons who had a right to "monumental fees," or fees for interments, will doubtless cause considerable controversy, and the copious notes of the editor will be found of great assistance. Section 7 of the Act removes the obligation of a Burial Authority to appoint a chaplain, but provides that existing chaplains cannot be removed, as the power of removal is given to the bishop alone, and Section 8 repeals the requirement of Section 1 of the Burial Laws Amendment Act, 1880, which required 48 hours' notice to be given of intention to bury in a burial ground. The schedule contains a list of enactments repealed by the Act of 1900. Included in the volume are the Public Health (Interments) Act, 1879, the Cemeteries Clauses Act, 1847, and the Local Government (Joint Committees) Act, 1897, as well as the Directions to Burial Authorities issued by the Secretary of State of the 1st January, 1901. Mr. Brooke Little has, in the editing of this volume, performed his work with scrupulous care, and his impartial and learned discussions on the interpretation to be placed upon the various sections will do much to remove the difficulties which are so usually attendant upon the coming into force of a new Act.

Quantities: Vol. I., Road-making and Sewer Construction for the Use of Surveyors, Municipal Engineers, and Architects, with various Tables, &c., for Ready Reference. By J. BARTLETT, M.S.A. The St. Bride's Press, Limited. 218 pp., 8vo. Price 7s. 6d.

THE author of this book, who is one of the examiners to the Society of Architects, demonstrator of building construction and architecture, King's College, London, and a lecturer on quantity surveying, informs us in his preface that the book has been written at the request of numerous students whom he has taught during the past twelve years, and to provide a concise and ready reference to the numerous items that occur in the practice of a municipal and county surveyor's office, and their method of measurement. There is no doubt that the book will be welcomed by young municipal engineers, as it supplies a want which had not been hitherto met, for although there are numerous books on quantities and quantity taking as regards builders' work, there was none published, so far as we are aware, with regard to road-making and sewer construction. The methods of "taking off," squaring, checking, "abstracting," and "billing," are explained, and tabulated details are given, showing their application to the work, and also as to the methods of measurement. The preparation of bills of quantities is also illustrated, and altogether with the aid of this book the inexperienced should be able to master the difficulties of getting out quantities in such a manner that they would bear the test of examination in cases of litigation. Specimen forms of tenders and specifications for the supply of materials are furnished, but no specifications of street works or sewerage works are given. The value of the book would have been greatly enhanced by their inclusion, but doubtless this will be remedied in a future edition. The book is clearly printed on good paper and bound in a neat cover.

National Health Society.

OFFICIAL TRANSACTIONS.

APPOINTMENT OF LADY SANITARY INSPECTOR.—We have great pleasure in recording the success of another of the Society's students in obtaining an appointment as Sanitary Inspector, Miss Grace Looker having been chosen from among eleven applicants as Sanitary Inspector in the borough of Kensington. Miss Looker is a diplomée of the Society, having taken the full training course both for the examination of the Sanitary Inspectors' Examination Board and for the diploma. We would draw the attention of our readers to the fact that this is the seventh public appointment which has been gained by the Society's students within the last few months.

ASSOCIATION OF NATIONAL HEALTH WORKERS.—A general meeting of the Association was held on Saturday, May 11th, at 53, Berners-street, attended by fifteen members, Dr. Childs in the chair. The Secretary reported that the Association now numbered forty-eight members. The finances of the Association were found to be in a most prosperous condition, there being a balance of £3 7s. 8d. in hand, with no prospective expenses till January, when the subscriptions are again due. December 30th was decided on as the date for the next bi-annual meeting, but the date is subject to alteration at the discretion of the Executive Committee. In view of the recent additions to the Executive Committee, a resolution was carried that the *personnel* of the Committee shall remain as it is until next May. The monthly "At Homes" are suspended for the present; members of the Association will be communicated with when they are recommenced.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

As I know of numerous surveyors who have sent in applications for the vacant appointment of Engineer to the municipality of Capetown, South Africa, it will be of general interest for me to state that six names have been selected by the London Agents of the Capetown municipality, viz., Messrs. S. E. Burgess, South Shields; W. Dyack, Aberdeen; A. Fidler, Southend-on-Sea; G. T. Lynam, Burton-on-Trent; J. Saunders, Chichester; and F. Wood, Bacup; and that the final selection will be made about the middle of June.

The Municipal Engineers' meeting which was held at Oswestry on Saturday last was an interesting and successful one, and appreciated by every member present, and Mr. Lacey, the courteous and popular Borough Surveyor, spared neither time nor trouble in achieving this result. The record of work carried out by him administratively is one which does him credit.

The extremely low cost of the construction of the bacteria beds, viz., £2000, for the efficient purification of the sewage of a population of 10,000, or 4s. per head, deserves especial notice, and is deserving of comparison with a scheme of land treatment submitted by Messrs. Taylor, Sons, and Santo Crimp in 1895, the estimate for which was £15,000. Similarly, too, the cost of treatment is abnormally low, viz., £225 per annum, or equal to 5¼d. per head of the population. I should like to hear of any district which can beat these figures.

The main secret of success in producing such low cost is, it should be known, to be attributed to the perversity of the Local Government Board, which refused to sanction a loan because there was no provision for the subsequent treatment of the effluents on land. The refusal of the Board, it often happens, is a blessing in disguise, as in the case of Oswestry, for the cost of the work, when defrayed from revenue, is considerably less than would otherwise be the case, and the results are equally as good, for the analyses which Mr. Lacey laid before the members, and which were made by himself, showed a remarkable degree of purification.

I am given to understand that a meeting of the Municipal and County Engineers' Association is to be held at Chichester, on Saturday, June 1st, when I have no doubt there will be a good muster of members. Chichester, I may point out, is one of the oldest cities in the kingdom, and its old city walls are still in existence, and utilised as promenades. The place is one of very considerable antiquarian interest; it has a population of 11,000, with a rateable value of £53,000, is a borough, and, like most old cities, possesses landed property, the rents from which are used in alleviation of the rates. Like most towns, too, it has its difficulties with regard to the disposal of its sewage, and the Council has recently been unpleasantly reminded thereof.

I would suggest to the Council of the Association that with a very slight amount of trouble they would be able to manifest consideration for the interest and convenience of members if they would deign to have arrangements made with the railway companies for the obtaining of tickets for members intending to travel from London at reduced fares. This neglect in the past has not been viewed by members generally as excusable, and might be atoned for by the exercise of a trifle more zeal than has been yet perceptible.

There has just been introduced into this country a new Automatic Fire Detector for use in buildings, ships, and collieries, which consists of a copper wire run round the rooms, generally near the ceiling. The wire has no break in it, and expands with heat, causing an attachment to drop which closes the circuit and electrically and instantaneously giving the alarm and indicating the exact position of the outbreak. It is not affected by seasonable variations in temperature, as is the case with some of the older forms of fusing media and thermometers, which had a tendency to go off under such conditions. The inventor is Mr. Chas. E. May, the Senior Mechanical Electrician to the Government of New Zealand, and in that colony it is in general use, and in connection with the fire brigade stations. The English company who are introducing it are the May-Oatway Fire Appliances, Limited, 53, New Broad-street, London, E.C., of which Sir Eyre M. Shaw, K.C.B., is chairman; Mr. G. H. Oatway the managing director; and Sir W. H. Preece, K.C.B., F.R.S., the consulting electrical engineer, the latter of whom advises that the system is reliable and thoroughly practical.

I adverted recently to the suggested bye-laws as to new buildings for rural districts which have been drafted by the Surveyors of the Chelmsford and Maldon Rural District Councils and to one or two of the proposed modifications from the Local Government Board's model bye-laws. Other alterations, in addition to those previously mentioned by me, which are of general interest, are (1) that permitting "walls of 4½in. in thickness for buildings not exceeding 8ft. in height or 12ft. in length where such buildings are to be used for a wash-house, pantry, water-closet, earth-closet, privy, tool, or cycle-house only." This clause appears to me to require limiting to such structures when they are built as detached or semi-detached buildings, otherwise when enclosed in the main building they could be of 4½in. walls only; (2) that prescribing that soil-pipes and ventilating pipes to house drains shall, where carried up the side of a building, terminate at a point not less than 3ft. above the eaves or any dormer-window.

It is also provided that "where in cottages the drain takes away the drainage from a sink waste only, the ventilating shaft at the highest point of the drain may be of a sectional area of a pipe or shaft of the diameter of 3in." This clause is indefinitely framed, and it is not clear as to whether it is intended to apply to every house or to a group of houses. If the latter, the proposed reduction of size of pipe is inadvisable.

There is also a clause prescribing the paving of the open space at the rear of dwelling-houses over an area of 50 square feet, which is too limited, and should not be less than 100 square feet, and one permitting "any addition to an existing building which shall not exceed one-fourth the original size, to be built of the same material as the existing building, providing that in no case shall the addition be greater than one-fourth the size of the building when it was first built"—a clause which I think will be found to be quite supererogatory. These suggested bye-laws show the "drift" as to wherein relaxation of the existing model bye-laws is required. Inasmuch, however, as the Local Government Board are themselves preparing a new code for rural districts, it is doubtful whether those suggested will be approved by them, and it might be advisable to wait until the promised series is ready. Senex.

It is anticipated that the report of the Royal Commission on Sewage Disposal will appear before the close of the present year. It is not at all improbable that some of the members will present minority reports.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

AND

Journal of Sanitary and Municipal Engineering.

MAY 23, 1901.

THE SMALL OWNER.

IN a recent issue we pointed out some of the reasons which accounted for the laxity of public health administration in rural districts, the chief reason being the supineness of the Rural District Councils owing to the general character of their constitution. There are, however, other difficulties which are experienced to an equal degree by Urban Councils, not so much, perhaps, in the large towns, but, at any rate, in the ordinary county boroughs. One of these difficulties is the position of the small owner. We may illustrate the point by taking a typical case which was recently brought to our knowledge. Two properties were reported to the Local Authority by a certain Sanitary Inspector as nuisances in respect of a lack of proper sanitary accommodation. The usual proceedings were instituted for the removal or remedy of the nuisances, and in due course an order from the Court was obtained for the execution of the necessary works. The time limit for the execution of the works expired without anything having been done in either case. The next step, of course, should have been the execution of the works by the Local Authority, and the charging of the expense to the respective proprietors. In the one case, the owner being known to be a man in good circumstances, and the failure to comply with the order of the Court being due, probably, to obstinacy or sheer pigheadedness, no compunction was felt in carrying out the remedies provided by the Public Health Act. But in the other case, the owner was a widow, who pleaded extreme poverty as the reason for her inability to do what was required. The house of which she happened to be the fortunate—or unfortunate—owner was a small one, partly occupied by herself, and partly occupied by lodgers, from whom she derived the means of subsistence. For the sake of our illustration, we shall suppose that it was acquired by her by succession, an old house which had descended in the family. It represented her worldly all, and she had not the necessary capital to bring it up to modern sanitary requirements. In the knowledge of these circumstances, the Local Authority desisted from further prosecuting the matter. They did so on the ground that were they to carry out the necessary improvements, the expense would be irrecoverable from the owner except by attachment and sale of the property itself—an extreme measure which they hesitated to adopt—and, on the other hand, they did not feel called upon to expend public money in improvements which would enhance the value of the property, and so enrich the owner. The dilemma is easily intelligible, but the result was to leave the nuisance unabated. The whole proceedings were rendered fruitless, and an undesirable distinction was drawn between the well-to-do and the impecunious owners.

Now, according to our humble conception of the Health Laws, it is the duty of the Sanitary Authorities to carry out the provisions of the Public Health Acts for the removal of nuisances wherever they exist, without distinction of person, and irrespective of any considerations regarding the circumstances of the owners. It must be borne in mind that the ownership of property carries with it responsibilities as well as privileges. If owners are unable to discharge the responsibilities, they must forfeit the privileges, for the whole framework of our Public Health Acts rests upon the principle of the responsibilities incidental to ownership. If exceptional consideration is to be shown to the "small owner" the

consequence will be to make him an obstacle to sanitary administration.

It is customary in these days to read in certain sections of the Press philippics against the bloated owner of slum property, who makes his fortune out of the exorbitant rents he exacts from the suffering poor. It is not our purpose here to waste any sympathy on this class of person, who generally deserves all the abuse he gets, but the truth which lies in the opposite direction is apt to be overlooked. The modern tendency is to encourage working men to become their own landlords, and the ideal of a peasant proprietary is held up to us. From many points of view—the social, the economic, the political—we fully appreciate that ideal; but from the sanitary standpoint it is attended with certain difficulties, and even dangers. These are that the proprietor without capital will be unable properly to bear the burdens or discharge the responsibilities that are inseparable from ownership. In the ordinary course of sanitary administration it is often found difficult to get the small owner to carry out necessary improvements, not so much from lack of will as from lack of means. "The bloated slum owner," to whom reference has been made, is frequently more easy to deal with. He may be powerful, but he can be brought to his knees, and considerations of sympathy can have no place in dealing with him. In our illustrative case these humanitarian considerations formed the element of weakness. To attack a property for the expense of the improvements may seem hard, but if the only alternative is to allow the nuisance to remain, with the possibility of disease following in its wake, that may be even harder to the neighbourhood. Humanitarian considerations should have the fullest play, but they must give place to care for the public health.

The Usher Institute of Public Health.

One of the most princely benefactions to the University of Edinburgh in modern times has been the providing of a Public Health Institute by Sir John Usher, at a cost of £20,000. In making the gift, Sir John had it in view that the Institute, though handed over to the University, and placed under its immediate control, should also be available for the use of the Municipal Public Health Department, and nothing, we should imagine, could have been more suitable. The Institute, which is now rapidly approaching completion, has been designed and equipped in accordance with the most modern scientific ideas, and no effort has been spared to make it worthy of the great School of Medicine to which it is attached. In it the work of bacteriological examination will be carried out under the most auspicious conditions. All these advantages were intended to be placed at the disposal of the Corporation; rooms were to be placed at its disposal in the Institute; it was to have the use of the appliances for the examination and samples; and was, in short, to be saved the expense of independent buildings and equipment, as well as the salaries of a skilled bacteriologist and his assistants. The scheme of arrangements under which the Institute was to be placed at the service of the city has, however, been considered by the Public Health Committee, and they have decided that they are unable to recommend its acceptance. They consider, it is minuted, that the responsibility lying on the Corporation with regard to the public health of the city can only be met by having a complete bacteriological laboratory in connection with the new city hospital. The Public Health Committee may have excellent reasons for their decision, though we do not know what they are, but it seems to us at first sight that it will involve not only much overlapping of effort, but a very large unnecessary expense. The matter has still to be decided by the Town Council, and it is of such importance as to demand the most earnest and careful consideration.

A Good Beginning.

A few weeks since we recorded the arrival at Brisbane of Dr. Ham, the newly-appointed Public Health Commissioner for Queensland. The papers since received weekly have recorded various movements of Dr. Ham, by which it was clearly demonstrated that he intended to be something more than a mere ornamental head of a department. This week we have received copies of an interesting correspondence which has taken place between the Commissioner and the Brisbane Municipal Council. Dr. Ham has evidently been keeping his eyes open during his early connection with the capital city. He opens the correspondence by emphasising the importance of extra sanitary precautions being taken in order to prevent the plague again securing an entrance into the city. But there are other things he desires to have reformed. He finds that certain provisions of the Public Health Act are being contravened, and he requests the "Local Authority to be good enough to cause such inspection to be made, and such works to be executed, as will effectually abate such nuisances injurious to the public health" within its area. Appended to the letter is a list of about a dozen different places where nuisances were found to exist. They comprise foul drains, stagnant water, filthy premises, &c. A public convenience comes in for special condemnation. There is a "defective trap, and bad ventilation of the drain; uncleanliness of the premises, an old bell trap which allows sewer gas to escape freely," and so on. The Council is informed that prompt action is requisite, and that if this is not taken within fourteen days "an order will be issued instructing the Authority to do its duty in the matter." The letter is written in the most friendly spirit, and the Council immediately instructed the necessary works and inspections to be carried out. A further letter from the Commissioner deals with the question of trapping private drains, and contains some excellent suggestions to the Council for their future guidance. Dr. Ham's action in thus first dealing with the chief city of the Colony is having an excellent effect, and the other Authorities are

setting to work to put their affairs in order, and thus obviate the necessity of similar communications being addressed to them.

The Birmingham Water Scheme.

The Water Committee of the Birmingham City Council last week issued an interesting report on the progress made with the works which are to bring the new supply from Wales. From it we learn that the weather experienced in the Elan Valley since December has not been favourable to rapid progress in the execution of the works. At Caban Coch the dam has been completed to a height of 82ft. above the river, right across the valley, leaving a height of 90ft. still to be built. On the abutments an additional 28ft. has been built. The dam and viaduct at Craeg-ddu are practically as last reported, that is to say, only the roadway and parapets remain to be done. At Pen-y-gareg the wall is built up to 925ft. O.D., that is 20ft. below crest level; and at Craig Goch to 1030ft. O.D., or 10ft. below the crest, over which the viaduct has to be built. Considerable progress has been made with the excavation for the foundation of the Dolymynach Dam, and the driving of Dolymynach Tunnel is proceeding steadily, but the hardness of the rock encountered prevents very rapid progress. Good progress has been made with the lining of the Foel Tunnel, and with the portion of the aqueduct which is being carried out by administration. After referring to various contracts, the Committee show that the amount expended on the works in the Elan Valley during the year ended March 31st, 1901, was £181,859 8s. 4d., giving a total of £1,007,019 5s. The total rainfall registered on the watershed for the year 1900 was 63·04in. In order to permit of the re-arrangement of the farm holdings on the Elan Estate, which will be necessitated through the filling of the reservoirs at present under construction, notice has been given to the occupiers to terminate their present tenancies at Lady Day, 1902, and steps have been taken with a view to the rearrangement of the holdings, having reference to the altered conditions which will obtain when the reservoirs are filled.

A Voice from the Past.

The present unsatisfactory state of Capetown shows the folly of allowing towns, or even villages, to spring up without any regard to the laws of health and good sanitation. Thousands are to-day congregated in that town, and although it is the natural entrance by which emigrants enter South Africa, there is little or no provision for the accommodation of such a class. This fact has brought to the minds of some the memorable words of Sir Bartle Frere, on the eve of his departure from the Colony many years ago. His closing words were an earnest plea to the workers of the place to pay attention to the need for providing good houses, such as would be adopted to preserve health, and to secure happy homes in a crowded city. "What constitutes," he asked, "a good workman's lodging, what provision should be made for adequate water supply, good drainage, and other essentials for health in the building of a house, are matters in which many of your working men are masters of their craft. I would ask them to take a patriotic citizen's interest in spreading this knowledge among their less well informed neighbours and fellows. Let a few of them combine together to provide model lodging-houses for themselves and their families, to influence, as far as they legitimately may, the action of legislation, where legislation is required on the subject, and we may in future hear less of those terrible epidemics which occasionally decimate the younger portion of our population in South Africa, and which are, as you and I know, in the vast majority of instances, entirely preventable by reasonable care and adequate sanitary arrangements." Alas! all were then too much engrossed in the search for riches to heed the good advice, but the people have had to pay heavily for their neglect. An attempt is now being made to reach the ideal set forth by Sir Bartle, but the intervening years have left their mark behind, and much will have to be destroyed before any real good can be accomplished.

The Condition of Londonderry.

The constant recurrence of zymotic disease in Londonderry has long been a matter of comment, and some time ago the Irish Local Government Board sent down Dr. Bigger, one of its Medical Inspectors, to hold an inquiry into the sanitary condition of the district. He has now issued his report; his description of the place is sufficient explanation of the presence of disease in its midst. Speaking of the houses, he says that they are usually one-storey, and built with stone or brick, many of them having only two rooms; nearly all are self-contained, only a very few being tenement houses. In the older parts of the town the houses are old, dilapidated, damp, deficient in light and ventilation, some situated in narrow lanes and back passages; many are overcrowded, and are kept in a dirty state. The yards in many instances are unpaved, or only partly paved, and defectively drained; some have no back-yards and no back doors or back windows; others have a common yard and a common privy, which serves for several houses, but with few exceptions water is supplied in every house. Of the 7000 houses, there are 1340 houses under £4 valuation, 1970 houses valued between £4 and £6—in all, 3310 houses, being nearly half of all the houses in Londonderry, at or under £6 valuation. Dr. Bigger, in conclusion, urges the Corporation to give immediate attention to measures of reform. "The insanitary houses, many of which are not capable of being made sanitary, should be closed; the others should be so repaired and improved that they would be sanitary. Proper sanitary conveniences should be provided where required. In houses having no back entrances these should be provided where possible; but in the case of houses having privy middens, and where no back en-

trances can be provided should either be demolished or provided with water-closets and dry ashpits, instead of these privy middens, as the contents from these privy middens can only be cleaned out by the contents being carried through the dwellings, thus causing a nuisance which is injurious to the health of the occupiers. In houses having a back entrance, but with defective midden privies, these should be repaired, and the floors and sides concreted to prevent pollution of the subsoil. Lanes, passages, and small yards should be channelled, drained, paved, &c. Eave spouting should be erected where required. The manure depôts in Bishop-street and at Waterside should be closed. The various railway companies might be induced to erect manure sidings, so that manure might be carted there and emptied into wagons and taken to the country and sold. The Sanitary Authority might also erect a four or six-cell destructor for the purpose of destroying decaying vegetable matter and rubbish, &c. More attention should be paid to carrying out of the bye-laws, particularly those relating to dairies, cowsheds, and milkshops, and the keeping of animals."

Beverley's Noble Benefactor.

One of the best public gifts ever recorded has just been made to the ancient Corporation of Beverley. A public-spirited individual, who prefers to remain anonymous, has been quietly buying up the entire slum area of the district, and has now made a present of it to the Corporation, in order that it may be taken in hand and made fit for the habitation of human beings. Superficial people may question the utility of such a gift, but experienced men will at once see the enormous benefit conferred upon the ratepayers by such a gift. If it had been known that the Corporation was desirous of purchasing or dealing with this property, every difficulty would have been placed in the way of such action, and most probably the purchase, if made at all, would have had to be done through the exercise of compulsory powers, and at a largely enhanced cost. This, as is well known to our readers, is the worst item in all public improvements. But the gift now received will enable the Corporation to erect new buildings, which will not only be a great improvement to the district, but which they will be able to let out at rents within the reach of the poorer members of the community. It may be that the gift does not advertise itself so largely as a library or public garden would, but its real value is far in advance of these, great as their usefulness may be.

Advance in India.

From the *Punjab Gazette* we learn that an important alteration has been made in the old rules framed by the Punjab Government under the District Board and Municipalities Acts. The alteration is connected with the recent decision of the Local Government to appoint a Sanitary Engineer for the Province, who will be ready to advise and assist all Local Bodies in projecting and executing sanitary works. This officer will be in excess of the ordinary Public Works Department establishment, and in order to recoup the Government, for the expense entailed by his appointment, it is intended that Local Bodies utilising his services should pay fees therefor. As regards sanitary projects, the Sanitary Engineer and the Sanitary Board to be appointed will take the place of the Superintending or Executive Engineer as the approving Authority, and certain powers have been given to the Sanitary Engineer as to the agency by which projects are to be designed and for the supervision of their execution. The fees which Local Bodies will have to pay for these services are set forth in the revised rules. The advantage of the arrangement is that Local Bodies will obtain for the fees so paid by them the services of a specialist, who will be able to devote sufficient time to each project, especially in its preliminary stages, when insufficient study of the features of a case is liable to lead to the work being started on wrong lines. At a time when plague seems to have got a more settled hold of the Province than ever, and is spreading abroad through the rural tracts with unpleasant energy, the necessity of an improved system of sanitary administration does not need emphasising, and the Government may be congratulated on the timely innovation.

Sanitary Inspectors' Associations.

NATIONAL UNION: NORTH WALES DISTRICT CENTRE.

The fourth sessional meeting of the above was held at the Guildhall, Carnarvon, on Saturday, when papers were read by Dr. Fraser, Medical Officer of Health, Carnarvon Combined Sanitary Districts, and Mr. R. U. Parry, Sanitary Inspector, Gwyrfai, dealing with the recent small-pox epidemic in Carnarvonshire.

Mr. Ernest Worrall, Surveyor, Penmaenmawr, presided over a goodly and representative attendance of members.

Dr. Fraser stated the source of the outbreak had been clearly traced to a visitor from one of the large towns. Altogether some seventeen cases occurred during a period of four months; fourteen recovered and three proved fatal. All those who recovered had been vaccinated, whilst of the three fatal cases, two had not been vaccinated, and the third case was exceedingly doubtful. He described in detail the preventive measures adopted, which included prompt removal of patients, thorough disinfection of houses and goods, and quarantine. So completely were these carried out that only in one house did a second case occur, and here gross carelessness of the inmates was proved. He eulogised the services rendered by the District Inspectors, and emphasised the necessity for the erection of hospitals to be in readiness for any such outbreaks.

Mr. Parry described the difficulties encountered from the people in putting the remedial measures into force, many of them failing to properly realise that small-pox was in the district until the deaths became chronicled, when but little further resistance was shown.

A discussion ensued, at which the readers of both papers were thanked.

Public Works.

SEWERAGE.

Sanction has been obtained by the Wantage Urban District Council to the borrowing of £5800 for sewerage and sewage disposal.

The Bideford Urban District Council has obtained permission to borrow £2500 for carrying out the East-the-Water drainage scheme.

Colonel Slacke held an inquiry at Hungerford last Tuesday in connection with the application to borrow £5812 for the purpose of sewerage and sewage disposal.

The Blaby Rural District Council has adopted another scheme of sewerage for the parish at an estimated cost of £7500. The Leicestershire County Council has approved the scheme, and application will be made to borrow the money.

Mr. Lawford, the Engineer, attended before a meeting of the Langport Parochial Sanitary Committee last week for the purpose of consultation on the sewerage scheme. In reply to questions, he said that in his opinion the scheme suggested for adoption was the cheapest and best. The earth-closet system would satisfy the Local Government Board, but it would become more expensive in the long run, and was better adapted to scattered districts rather than to towns. It was eventually decided to appoint a deputation.

The Bradford Corporation Bill again came before the Committee of the House of Commons of which Mr. Heywood Johnstone is chairman, last week. The opposition to the sewage proposals of the Bill was continued. Mr. Samuel Rideal, consulting chemist, of London, was further examined by Mr. Longstaffe. He said the Bradford sewage was of a very weak character. Finally the Committee proposed to give compulsory powers to the Corporation to take for this purpose land on the south of the river as far as Strangford-hill.

Last week's ordinary meeting of the Leeds Corporation Sewerage Committee was invested with special interest in consideration of the recent rejection of the Gateforth sewage scheme by the House of Lords Committee, and there was a fairly good attendance to hear from the lips of the chairman (Alderman T. W. Harding) an account of the Westminster proceedings. The Chairman having made his report, various possibilities and contingencies were talked over, and the situation generally was discussed. It was, however, deemed advisable not to allow any expression of opinion to go forth to the public at present, and in order to ensure due secrecy the Corporation officials at the meeting were asked to retire while the subject was being debated. Afterwards Alderman Harding excused himself from making any statement to the Press, on the ground that it is obviously impossible for the Committee to be in a position at this early stage to come to a definite conclusion as regards an alternative or revised scheme. We understand, however, that the feeling of the meeting was averse to any abandonment of the Gateforth project; and it may be that, as happened in the case of Bradford, a recommendation will be forthcoming ere long in favour of another application to Parliament on modified plans. One of the points to be carefully considered in that connection is the possible attitude of the West Riding Rivers Board; but this, along with suggestions that may occur during the next few weeks, will probably occupy the Committee's attention at more than one subsequent meeting. Meanwhile, the Chairman proposes at the next meeting of the City Council, on June 5th, to review the whole circumstances of the case, and opportunity will then be afforded for free discussion.

Sanction has been obtained to the borrowing of £50,000 for sewerage and sewage disposal works at Stamford, and tender for a loan will be invited at once.

The Halesowen Council has decided to apply to the Local Government Board for sanction to an additional loan of £1438 required for the completion of the Hill sewerage system.

The West Penwith Council has authorised the chairman to affix the seal of the Council to a mortgage on the rates of Marazion for a loan of £1040, for carrying out sewerage works.

At a recent meeting of the Sewerage Committee of the Aberdeen Town Council correspondence was submitted with the Aberdeen Land Association with regard to the Bleachfield Burn. It was resolved that the Town Council should take over the Burn and cover it in as a stone water culvert, at a cost of £1460. It was calculated that this expenditure would save an outlay in another direction of over £1600. A letter was read from the Board of Trade agreeing to the construction of the outfall at Girdleness.

At the Moffat Town Council meeting recently, plans and estimates prepared by Mr. T. O. Niven, C.E., Glasgow, for a scheme for the purification of the burgh sewage by bacterial treatment was submitted. The total estimated cost of the works is £4137; £450 is reckoned for engineer, inspection, and legal outlays, and £225 for wayleave and tenants' claims for compensation, making a total of £4812. The plans and estimates were approved, and the Clerk was empowered to secure a loan of £5000 to meet the expenses of the scheme. Provost Kennedy was appointed the representative of the burgh to attend a meeting of Local Authorities (county and burgh) to be held at Dumfries, with a view to providing a combination hospital for the separate treatment of small-pox.

WATER.

In consequence of the opposition having been withdrawn, the Rugby Water and Improvement Bill has been taken from the consideration of the Committee of the House of Lords, before which it was to have come along with several other Bills in the course of this week, and referred back to the Earl of Morley as chairman of the Committee on Unopposed Bills.

The Bill under which the Urban District Council of Broadstairs and St. Peter's seeks power to purchase the undertaking of the Broadstairs Water Company, to construct additional waterworks for the public supply, and to make further and better provision for the improvement, health, local government, and finance of the district, appeared in the list of proceedings before a Select Committee of the House of Lords last week.

At length Barrow-in-Furness is in the way of obtaining the much-needed additional water supply, the essential enabling Bill having been passed by the House of Lords Committee. The supply will be obtained from the upper valley of the Duddon and from Seathwaite Tarn, with the stipulation that the Corporation shall not take more than the amount of water they want—that is to say, 2,000,000 gallons a day when there is a daily flow of 5,000,000 gallons, and not more than 3,000,000 gallons at any time.

The Llanelly Urban Council is constructing an additional reservoir at a cost of £67,000. The Surveyor reported progress to a special meeting of the Waterworks Committee on Thursday, and subsequently the members inspected the work. The contract provides for completion of the work in July of next year, but the contractor, Mr. Louis P. Nott, is prepared to bring it to a finish in March for a consideration of £1000. After providing several extras, the actual cost, it is expected, will be some £4000 below the sum borrowed for the work.

For the week ending May 4th 195,752,000 gallons of water were supplied by the Liverpool Water Committee to Liverpool and other places within and outside the compulsory limits. The supply for the week ending May 11th was 188,812,000, both weekly figures being beyond those for the corresponding weeks of last year, and due to some extent to the summer-like weather.

At a recent meeting of the Merthyr Waterworks Committee the proposed construction of a line of water pipes from the Upper Neuadd reservoir to Dowlais for the purpose of additional water supply was discussed at some length upon a communication on the subject from Mr. Deacon, C.E. It now appeared that as the cost of iron had decreased it would be more advantageous to go in for the high-level scheme with iron pipes than to construct on a lower level a line of earthenware pipes. It was decided that Mr. Deacon be authorised to lay before the Committee specifications and drawings for the high-pressure supply of the two alternative quantities of water.

The Water Committee of the Glasgow Corporation at a recent meeting had under consideration the rates to be charged for water during the coming year. It was reported that there was a deficit, mainly due to an increase of £8000 in the interest charges during the past year and the cessation of the steady expansion of the demand for water for trade purposes which has been going on during the past decade. There has also been an increase in the working expenses, and the decision by the House of Lords with reference to the payment of teinds represents an expenditure of £4000. It was unanimously agreed to retain the domestic rate within the limits of compulsory supply at 5d. in the £1, and that outside the limits of compulsory supply at 10d. in the £1, also to retain the public water rate at 1d. in the £1, but to raise the meter charge from 30s. per 100,000 gallons to 33s. 4d., the 3s. 4d. of an increase being the amount of the decrease which took place two years ago.

A Local Government Board inquiry has been held at Gloucester just recently with reference to the application of the City Council for sanction to borrow £7000 for works of water supply, including the construction of works in the parishes of Newent and Upleadon. The Town Clerk briefly explained the object of the application, saying the Corporation had accepted, subject to the approval of the Local Government Board, the tender of Messrs. Cruwys and Hobrough, Gloucester, amounting to £6968 2s. 10d., for constructing an additional service reservoir at Madam's Wood, Upleadon, near Newent; and it was decided to ask for a loan of £7000 in order to cover incidental expenses. The proposed new reservoir would have a capacity of 1,250,000 gallons, which, added to that of the existing one, which held 600,000 gallons, would make provision for 1,850,000 gallons at Newent.

A Local Government Board inquiry was held at Rowhedge last Thursday in respect to the application by the Lexden and Winstree Rural District Council to borrow £3100 for works of water supply for Rowhedge. Dr. J. W. Cook explained that the water at the present time was derived from a well at the top of Albion Hill, a spring in the brewery grounds, a brook in Chapel-street (which water was of a very doubtful character), and private wells. The sewage was discharged into the river through old drains, and it was very possible that the sewage from those drains might pollute some of the present wells. In 1893 an outbreak of typhoid occurred, and an analysis made of the water in the wells proved unsatisfactory. The scheme, as now put forward, was then prepared, but on account of the opposition of the parish the matter dropped. The scheme generally was to obtain the water from the deep well at the brewery. It was sunk 305ft., 175ft. being into chalk. The analysis made the previous week by Dr. Thresh showed that the water was good

A special meeting of the Finance and General Purposes Committee of the Withernsea Urban Council was called last week to consider the water supply question. The Surveyor (Mr. Savile) read his report as to a visit of inspection to Welwick with Mr. George Cammidge. He said that as far as outward appearances went there seemed to be an abundance of surface springs. He did not recommend Welwick as a site for waterworks, as it was some distance from the railway station, which would necessitate a heavy cartage bill for coals, and then the cost of laying pipes from thence and royalties would be pretty considerable—about £7000. After discussion, the question was again adjourned.

The contract for the erection of a large new pumping station at Wimborne for the Bournemouth Water Company has been placed with Messrs. Burt and Vick, builders and contractors, of Poole. For a long time past the work of excavating a well has been in progress, and is now completed. The company has been lucky enough to find a splendid supply of water. The well is 200ft. in depth, and about 10ft. in diameter, and has a capacity of three million gallons per day. It is over this well, which is situate near Walford Bridge, that the pumping station is in course of construction, with all the other necessary buildings, including boiler-house, coal store, workshops, small reservoir, &c. We understand that the contract price exceeds considerably more than £6000, and it will take probably close upon twelve months to complete the work. The contract was obtained by Messrs. Burt and Vick, who were in competition with a large number of other firms in the neighbourhood.

Last week the members of the Waterworks Committee visited Walshaw Dean for the purpose of viewing the progress being made with the new reservoirs. They left the Town Hall at ten o'clock in two wagonettes, and were accompanied by the chairmen of the other committees, the Town Clerk (Mr. Keighley Walton), Mr. Hill (the engineer), Mr. Tempest (the contractor), and other officials. The company first alighted at White Hill Nook, and had a look round Dawson City. Then they journeyed by the new tramway to Blake Dean Bridge—a distance of three miles. From this point they were driven forward to Walshaw Dean. Nearly 200 men were found at work, and great headway is being made with the puddle trenching of the embankment of the first reservoir. The work of preparing the second embankment is also in progress. So far, in the trench driving, nothing of a loose or unsatisfactory character has been met with. When the bridge at Blake Dean, crossing the Hebden, has been completed, it will be possible to run trams right to the second embankment, a distance of 5½ miles. It is expected this work will be finished towards the end of the month, and then rapid progress may be looked for. In about a month's time there will be eight locomotives on the works at one part or another. Leaving Walshaw Dean the Committee made their annual inspection of Widdop reservoir, and found everything in good order.

LIGHTING.

We understand that the Parish Council of Trefriew has come to an arrangement with the Electric Lighting Company, with a view of lighting the popular country health resort.

The directors of the Cape Town and District Gas Light and Coke Company recommend payment of a dividend on the ordinary shares at the rate of 11 per cent. per annum for the half-year ended 31st December last, making a total dividend of 10 per cent. for the year 1900, as compared with 9 per cent. for the previous year. A sum of £7500 has been placed to reserve, and £1684 carried forward to next year's accounts.

The Alfreton Gas Bill, which has passed the Lords, last week came before the Chairman of Ways and Means as an unopposed measure. The preamble was proved, and the Bill was sent for third reading in the Commons.

The New Swindon Gas Bill, which confers a number of further powers on the company, last week complied with the Standing Orders of the House of Commons, and was sent by the Examiner for second reading in the Lower Chamber. The Bill has passed through the House of Lords.

The Paisley Town Council met in committee last week and agreed to oppose the application of the promoters of the Clyde Electric Supply Bill for a way-leave through Paisley, and to lead evidence to show that it would be less expensive to keep outside, and that the route would not be much longer.

For the first time in the history of the Leeds Corporation Gas Department, the number of meters in the city has reached six figures. On April 30th, according to a return which has since been placed in the hands of a Corporation Sub-committee, there were in use 86,951 ordinary meters, 9454 prepayment meters, and 3817 prepayment meters with "cookers," giving a total of 100,222 meters.

Islington is not alone in having had to face, as the result of last year's working of its electric lighting installation, the unpleasant fact of a loss. From a report just issued it seems that Portsmouth has lost £1000 in the year ending March 31st last on its undertaking, which is an older one than that of Islington. In 1900 there was a profit of £1250 on the Portsmouth installation, while in the previous year there was a profit of £2,475, of which £1000 went to the relief of rates, and £1,475 to the reserve fund. To fall upon a year of a dead loss of £1000 is the reverse of consoling after profits such as those above mentioned. The loss is ascribed to the high price of coal.

The Mayor and Corporation of Bermondsey have been sued in the King's Bench Division by the South Metropolitan Gas Company for £884 2s. 3d., for gas supplied to the baths and washhouses at Rotherhithe. Since 1881 the person who had read the meter had made the mistake of reading the dial, which indicated that 1000 feet had been consumed as if only 100 feet had been consumed. The total amount consumed and not paid for was £2987, but the statute of limitations being pleaded, only £884 2s. 2d. could be claimed. The facts were not disputed, but the Borough Council were doubtful if they could lawfully pay the money. They could not make a retrospective rate, and they could not take money which was in the hands of the treasurer to pay the debts of the late vestry of Rotherhithe. Judgment was given for the plaintiffs for the amount claimed.

Last week the Select Committee of the House of Commons, of which Colonel Welby is chairman, further considered the Mond Gas Bill, under which power is sought to form a company to supply a patent producer gas which has been invented by Dr. Ludwig Mond, to an area of about 135 square miles in South Staffordshire. According to the promotors, the gas can be profitably supplied in large quantities at an all-round price of about 2d. per thousand cubic feet, at which price it will largely benefit the district by enabling manufacturers to provide themselves with power at a far cheaper rate than they can at present obtain it by means of coal gas or electricity. The preamble of the Bill was passed at a former sitting of the Committee, and the promoters now brought up clauses carrying out the conditions on which they approved the Bill. The clauses having been adjusted, the Bill was ordered to be reported to the House.

The Long Eaton Gas Bill, which has passed through the Commons, came on Friday before the Examiner. He found that the Standing Orders of the House of Lords had been complied with, and reported the Bill for second reading in the Upper Chamber.

The formation of the roads at Provan Gasworks has been so much delayed that the Corporation has cancelled it. The unfinished work has been taken in hand by Messrs. M'Alpine, the builders of the gasworks, and they will complete the contract for a sum slightly over £8000.

The Colwyn Bay and District Gas Bill, which provides for the transfer of the undertaking of the Colwyn Bay and District Gas Company to the Colwyn Bay and Urban District Council, came last week before Lord Morley's Committee as an unopposed measure. The preamble was proved, and the Bill will be sent for third reading in the Upper Chamber, after the production of the report of the Local Government Board and the minute of the Council's adoption of the scheme.

The preamble of the Clyde Valley Electric Power Bill having been passed by the House of Commons Committee, presided over by Sir James Woodhouse, the Committee met last week for the adjustment of clauses. Mr. Wilson, on behalf of the promoters, asked that they should be allowed to carry their mains through Paisley, else it would result in an additional expenditure of £20,000. Mr. Pollock objected to the decision of the Committee being upset on clauses. In the course of subsequent discussion, the promoters said they would not ask permission to carry their mains through Port-Glasgow. A clause by the promoters suggesting that subscribers might be allowed to use 25 per cent. of the power taken for motive purposes for lighting was objected to by Mr. Pollock, who thought 5 per cent. quite sufficient. The Chairman said that was a very important matter, as it had come up for the first time, and the decision of the Committee might form a precedent. The engineers on both sides, therefore, ought to assist the Committee without viewing the case solely from the point of view of this Bill.

In connection with the forthcoming introduction of electric light in Dalkeith, certain minutes of the Electric Lighting Committee have been laid before the Dalkeith Town Council, and these point to a satisfactory introduction of the light within the next two years. At a meeting of the Committee held on the 19th April, a letter was laid before the members, forwarding a copy of the Provisional Order in the form in which it was proposed to be issued, and requesting any observations to be made thereon which might be thought necessary. The additions to the Order since it was lodged were considered, and it was thought that as these were in favour of the Council by shortening the periods for taking over the works by the Local Authority and reducing the maximum price of electricity for public consumers, no observations thereon were deemed necessary. Mr. Sturrock, the Town Clerk, was, however, instructed to write the Secretary of the Board of Trade, intimating the agreement which had been entered into between Messrs. Crompton and Company, Limited, and the Council in regard to the public lighting of the streets of the burgh, and it was understood that this amendment was not controlled by the Provisional Order. A reply has been received from the Secretary of the Board of Trade referring the Dalkeith Council to Section 34 of the Electric Lighting Clauses Act, under which the questions of the supply for public lighting is left to be determined between the Local Authority and the promoters. This is a satisfactory confirmation of the arrangement mutually arranged by the Messrs. Crompton and the Dalkeith Committee.

GENERAL.

A Local Government Board inquiry was held at Yarmouth last week with reference to the application of the Council for sanction to borrow £1210 for works of street improvement.

Mr. F. H. Tulloch, C.E., an Inspector of the Local Government Board, held an inquiry at Richmond recently into the application of the Town Council for sanction to a loan of £1108 for street works.

The Strood District Council has decided to hold a special meeting to consider the question of providing a sanatorium for its district. An arrangement with Northfleet is probable, which would help them in regard to the cost.

At the annual general meeting of the Sick Nursing Association, at Sutton-in-Ashfield, it was reported that during the past year the nurse had paid 6898 visits to 211 cases, and had also been present at seven operations. This is the most remarkable record we have yet seen of the work done by a village or district nurse.

The Local Government Board recently ordered an inquiry into the prevalence of enteric fever at Ilkeston. The report of the Board's Inspector, now issued, states that the borough has not been free from enteric since 1881, and he regards the prevalence of the fever to be due, in all probability, to the pollution of the general water supply taken from the Nutbrook.

An examination of the Provisional Order granted by the Local Government Board with regard to the Quarry-hill insanitary area scheme of the Leeds Corporation shows that the Model Lodging-house, St. Patrick's Roman Catholic Church, the Hope Inn, and part of Riley's property have been eliminated from the scheme. With these exceptions the scheme is approved.

Preliminary steps have been taken for preparing a Bill to be promoted in Parliament for the construction of an electric light railway direct between Canterbury and Herne Bay, starting from Rhodans-town, Canterbury, and proceeding thence down Bridge-street, up the Military-road, and on to the Sturry-road. The scheme is independent of the Canterbury and Herne Bay Electric Light Railway.

The Financial Committee of the Glasgow Corporation recommends that the expenditure incurred in connection with the bubonic plague and small-pox outbreak in so far as it is in excess of the revenue of the year, should, to the extent of one-sixth, be included in the accounts of the present financial year, and carried forward as a deficit against the revenue of next year, and that the remaining five-sixths be charged in equal proportions against the revenue of next and four succeeding years—thus debiting next year (1901-02) with two-sixths of the entire deficiency, and each of the four following years with one-sixth.

The following from the *Cape Argus* describes some of the occurrences at a recent meeting to appoint additional sanitary officers. It says:—"The Mutual Hall was filled on Tuesday morning with applicants for the five new creations in the ranks of the Sanitary Inspectors. They consisted of all sorts and conditions, for in these plague days the hardened rogue just out of gaol, and the tender youth whose education has been neglected, excepting what he has picked up in the streets, consider themselves equally qualified with the most experienced for any post connected with municipal affairs in this city. One persistent person, in answer to a question as to what he knew about sanitation, said, 'No, I don't know the gentleman, but I understand what it is to be clean.' Being pressed further on the point, he said he had a Sunday bath regularly, and he was sure he could get other people to follow his example and be clean also. That candidate is still waiting for a billet, and so are most of the others."

The London County Council has agreed to lend the Shoreditch Borough Council £2440 for baths and wash-houses, and the Camberwell Borough Council £10,710 for the purchase of the freehold of its depôt.

The Town Council of Penzance is seeking the advice of its Medical Officer as to the proposed examination of dairy cows supplying the town with milk, for the purpose of ascertaining if the animals are suffering from tuberculosis.

At last week's meeting of the Hornsey District Council it was stated that a further six acres of land had been purchased adjoining their workmen's dwellings at a low rate, and that that would be utilised for the erection of more dwellings for the working classes.

A Local Government Board inquiry has been held at the Town Hall, Scarborough, relative to the application of the Town Council for sanction to borrow £1100 for the purposes of public walks and pleasure grounds in Manor-road, including the erection of public conveniences.

Numerous improvements have been effected at Weston-super-Mare since last season, others are in progress. The electric light works and the Queen Victoria Memorial (Free Library and Museum) have been completed. A pavilion and a third swimming bath, each to cost about £10,000, are being erected; a portion of the sea-front promenade is being widened at an expenditure of over £4000, and the new low-water pier is approaching completion. Free promenade concerts by the band of the Royal Artillery (Mounted) and other attractions are announced for the season.

On Saturday last Mr. J. White, Mayor of the Metropolitan Borough of Lambeth, presided over a large company at the Holborn Viaduct Hotel, who had assembled to celebrate the inauguration of the Borough. The Lord Mayor and Sheriffs were present, as well as most of the local Members of Parliament. Some interesting circumstances were brought out by the Lord Mayor in the course of his speech. Proposing the toast of the "Borough of Lambeth," he said it was the first time upon which the Lord Mayor of London had had the distinguished honour of proposing success and prosperity to the Borough of Lambeth, and he regarded it as a very important privilege, and one of the most pleasurable character that it had fallen to him to propose such a toast upon that occasion. They expected a great deal from the new Municipalities. The Borough of Lambeth covered 18 square miles, and contained 301,873 inhabitants, so that it was the second largest of the London Boroughs, and the eighth largest of the Boroughs in the Kingdom. They were all gratified to know that the Borough occupied such an important position in the Kingdom. In Lambeth they had five public libraries, and conjointly with other Boroughs controlled two more. The rateable value of the Borough was £1,857,808—a very large and important rate for a Municipality to have. With such a large rating power, it was of importance that the Council should embrace men of business, who were capable of carrying on the business of such an important Borough. The roads of which they had control were 160 miles in extent, and the Council numbered ten Aldermen and 60 Councillors, besides the Mayor. The Borough of Lambeth was full of historic interest. There was one Charter which went back to the time of Edward the Confessor; Kent-street occupied the site of one of the old Roman roads; and Lambeth Palace was full of historic associations, with its Lollard's Tower and other memories. He had, therefore, great pleasure in proposing the toast, and coupling with it the name of the Mayor. The Mayor replied, and referred to the position which the Borough occupied, and the work which the several Committees were carrying on. He hoped they would not fall short of the high standard expected from them in the future.

THE "penny-in-the-slot" telephones of Paris have not proved a success, and are to be closed.

A MOVEMENT is on foot in Manchester to municipalise the property at present owned by the Crematorium Company of that city. It is said that it can be purchased for £9000.

AN official notice has been issued by Dr. Charles Sanders, the Medical Officer of Health for the Borough of West Ham, stating that a severe epidemic of typhoid or enteric fever is raging in Canning Town and the surrounding districts. Dr. Sanders warns the inhabitants against eating ice cream, and allowing their children to partake of "hokey-pokey."

THE Select Committee of the House of Commons, presided over by Mr. Seale-Hayne, after several days' investigation, has found proven a Bill promoted by the London County Council to enable it to construct a number of new tramway lines, principally in the South of London, and to carry out certain street widenings. The Committee rejected provisions for the extension of a tramway along York-road, Lambeth, which was objected to by the South-Western Railway Company as hampering its Waterloo Station traffic, and also threw out the Farringdon-road extension, which was opposed by the Great Northern, on the ground of interference with its goods traffic.

AFTER three years' controversy among themselves and with the Local Government Board in regard to the site of a fever hospital—the present site and buildings being held by the Board to be unsuitable—Musselburgh Town Council last week, on a division, decided, on the motion of Mr. Kitto, that a full statement of the case regarding the hospital be laid before the member for the Leith Burghs, with the request that he ask a question in the House of Commons as to whether the Local Government Board are not exceeding their powers in ordering the hospital to be removed from its present site in consideration of the fact that a loan was granted, extended for the period of twenty-five years, for the purpose of providing the present hospital.

THE Tramways Committee of the Lancaster Corporation last week had before it a proposal from a Birmingham syndicate for the acquisition by them of the whole of the powers to construct and maintain electrical tramways in the borough obtained in the Lancaster Corporation Act, 1900. The scheme of the Corporation involves a cost of £70,000, and provides for a net-work of tramways on the overhead wire principle, bringing the growing suburbs of Scotforth and Skerton into touch with the centre of the borough. The Skerton length for the present is delayed because negotiations fell through with the Lancaster and District Tramways Company, who possess a line four miles in length from Lancaster to Morecambe, which is worked by horse power. The Corporation made the offer of 15s. per £1 share. This the shareholders refused to accept, and the negotiations dropped. The syndicate first had their eye on the Morecambe trams, and in approaching the Lancaster and District Tramways Company, which has done better in recent years, made the offer to buy out the undertaking at par, provided the directors were able to get the Corporation to give them a lengthy renewal of the lease over the Lancaster portion of the line. The syndicate at the same time made the proposal to the Corporation of Lancaster in the hope that it would follow the example of Barrow-in-Furness and sell its powers for the construction of the electric tramways. From what transpired at the Committee meeting last week, however, it is very improbable that the Lancaster Corporation, having made several efforts to municipalise its tramways, will, when within reach of the desired goal, barter away its rights, even though large inducements may be held out.

THE first meeting of the newly-elected managers of the Metropolitan Asylums District was held on Saturday last at the office of the Board. On the motion of Mr. E. White, seconded by Mr. T. Helley, Mr. R. M. Hensley was unanimously elected to fill the office of chairman for the ensuing twelve months, in succession to Sir E. Galsworthy; and on the motion of Mr. Drage, seconded by Mr. A. C. Scovell, Mr. J. G. Talbot, M.P., was re-elected vice-chairman.

SOME months ago some rather high death-rates were recorded in the large towns of the Punjab. These figures, however, are more than kept in countenance by the vital statistics of the neighbouring Province, just issued. The water-logged town of Kosi, in the North-West Provinces, heads the list with the alarming figure of 78 per 1000. Other notably unhealthy towns are Gonda, 56 per 1000 (defective drainage); Haldwani, 54 per 1000 (unsatisfactory sanitation); Dhanpur, 52 per 1000 (outbreak of cholera); Cawnpore, 51 per 1000 (urgent need for sanitary reform); and Ghaziabad, 49 per 1000 (pneumonia).

ON Monday last, in the House of Commons, Mr. Chaplin asked the First Lord of the Treasury if his attention had been called to the difficulties which arose under Standing Order 22, in the making of tramways in London, in order to facilitate the housing of the working classes; and whether, having regard to the pledges given by the Government in relation to that subject during the last Parliament immediately before its close, the Government proposed at an early opportunity to take measures to give effect to those pledges. To him Mr. Balfour replied he was not aware of any specific pledge of the kind mentioned by his right hon. friend, though undoubtedly there were very strong arguments to be urged in favour of the course he wished to see adopted. The alteration, however, of the Standing Orders would not complete the reform he desired. It would require legislation in addition. Mr. Chaplin continued his quest, and inquired, "Is my right hon. friend not aware, or has he forgotten, that on the third reading of the Housing of the Working Classes Bill I myself gave, on behalf of the Government, a pledge to this effect?" But Mr. Balfour was not to be drawn, and replied, "It has either escaped my memory, or my attention has not been called to it."

THE proprietors and factors of slum property in Dundee are up in arms against those who are charging them with being responsible for the unsatisfactory condition of certain portions of the town. They have memorialised the Town Council, and claim that they would be the last to deprecate any action calculated to improve the health and morals of the community and state that they were, perhaps, better acquainted than most people with the conditions obtaining in Dundee. They aver that it is contrary to reason to suppose that landlords and factors should suffer their properties to get into a state of disrepair. They record their objections to regulations for the provision of sanitary appliances which would never be used by the tenants, and against a one-sided agitation such as is at present being engaged in. It is alleged that the Cleansing Department itself does not carry out the enactments of the Dundee Police Acts in regard to the emptying of ashpits and other matters of sanitary administration. So far as sanitary appliances are concerned, it is asserted that a certain class of tenants grossly neglect their duty of keeping such in proper order, and that the Authorities, whose position, judged by a recent magisterial decision, have not done all in their power to check insanitary practices detrimental alike to the landlord's property and to the health of the tenants inhabiting it. An expression of opinion is given that the present division between the Sanitary Department and the Cleansing Department is not in the public interest. In this connection house factors complain that where an order given by the

Sanitary Department is carried into effect, the Cleansing Department has more than once declined to proceed with its work under the new conditions created thereby. The memorial, from the house factors' point of view, deals exhaustively with the question of insanitary tenements. The signatories and members of the Association are hopeful of being afforded an opportunity of appearing before the Sanitary Committee and Town Council in support of their views. On the part of some of those representing property interests it is asserted that the Authorities are shielding themselves behind the proprietors as an excuse for not carrying out and exercising to the full their powers of cleansing and supervision.

PERSONAL.

Mr. P. F. Rett has been appointed Assistant Sanitary Inspector for Lowestoft.

Mr. W. A. Nicholson has been appointed Surveyor for the Rural District of Halstead.

Mr. F. A. Ward has been appointed Assistant Engineer for the Rural District of Chelmsford.

Messrs. H. E. Anderson and J. H. Sutcliffe have been appointed Assistant Surveyors for Lambeth.

Dr. Gray has been re-appointed Medical Officer of Health for Holsworthy, and Mr. Webb Surveyor and Inspector of Nuisances.

Mr. M. Roberts has been appointed an Assistant Sanitary Inspector under the Leeds Corporation, and is located to the Holbeck division of the city.

The Local Government Board has sanctioned the appointment of Dr. Berryman as Medical Officer of Health for Llandovery, and Mr. John Roderick as Sanitary Inspector.

Mr. Trevor Duesbury, Chief Assistant Engineer at the City of Gloucester Electricity Works, has been unanimously elected Resident Electrical Engineer for Sutton Coldfield, at a salary of £200 per annum.

The Local Government Board has sanctioned the re-appointment of Dr. Boulton as Medical Officer of Health for Woodhall Spa, and Mr. Brocklesby Crookes as Inspector of Nuisances for another year at the same salary.

Mr. Edward C. Dutton, M.B., Ch.B. (Victoria), who for the last twelve months has been the senior resident Medical Officer at the Stockport Infirmary, has been appointed a Civil Surgeon (attached) to the forces in South Africa.

The term for which Mr. Thomas Michell was appointed Sanitary Inspector of Paddington, viz., one year, having expired, the Borough Council have re-appointed him at his present salary, £100 a year, pending the re-adjustment of salaries which is now under the consideration of the Special Staff Committee.

Lieutenant-Colonel W. G. King, C.I.E., I.M.S., Sanitary Commissioner, Madras, has recently left on leave for about six months. In his absence, Major A. E. Grant, I.M.S., Deputy Sanitary Commissioner, will act as Sanitary Commissioner, his place being taken by Captain J. W. Cornwall, I.M.S., Health Officer of the Madras Municipality, Mr. K. Mathew, Assistant Health Officer, acting as Health Officer until the Government of Madras can depute an officer to act for Captain Cornwall. This is the first time that Sir George Moore's suggestion, made some time ago and accepted by the Government, has been acted upon, namely, that the Health Officer of the Madras Municipality should be appointed by Government, with a view to recruiting the Deputy Sanitary Commissioner from that office. The arrangement has a two-fold use; it ensures for Government a trained officer as a sanitarian, and it secures for the Municipality a higher class of officer than it might otherwise secure for the salary.

OBITUARY.

DR. SPRAKELING.

Many will regret to hear of the death of Dr. Robert John Sprakeling, M.R.C.S., Eng., and L.S.A., Lond., J.P., who died at his residence, 58, Merton-road, Bootle, at an early hour on Wednesday, the 15th inst. Deceased, who was sixty-eight years of age, had been ailing for some time past. For close upon thirty years he had held the position of Medical Officer of Health to the Bootle Corporation with conspicuous success. In fact, he was the first medical gentleman appointed to this office since the incorporation of the borough in 1868. The deceased during his long official connection with the Corporation discharged his duties in an able and satisfactory manner. His knowledge of sanitary matters was wide and accurate, and it was mainly through his strong recommendations that there has been such a great improvement in the sanitary condition of Bootle during recent years. Ever since his appointment he took a special interest in everything that tended to improve the public health of the town. His annual reports, in which were embodied short but lucid intelligent accounts of the progress of sanitation in the town, upon all occasions were of a most interesting nature. The deceased gentleman was a member of the first Council elected in Bootle, being returned a representative for Knowsley Ward, but he retired in 1872 in order to take up the position of Medical Officer of Health. In 1885 he was appointed a justice of the peace for the borough, and in every respect he proved a most popular magistrate. For a number of years he acted as Medical Officer for the Bootle district in connection with the West Derby union. Deceased, who was an old member of the Bootle Lodge of Freemasons, has left a widow and grown-up family.

MR. WASHINGTON LYON.

We regret to announce the death of Mr. Washington Lyon, of Clifton House, Asylum-road. Mr. Lyon, we gather from a contemporary, was a Scot, who, upwards of half a century ago, founded the bleaching works in Leo-street, Camberwell, in partnership with his brother. After the Metropolis Local Management Act came into operation, Mr. Washington Lyon was elected to the Vestry (1856), and continued a member of that body until 1894, holding office as chairman of the Sewers and Sanitary Committee. From 1874 to 1886 he represented the ward of Cornhill on the Court of Common Council, being during that period chairman of the General Purposes Committee and chairman of the Port Sanitary Committee. Mr. Lyon will be best remembered by our readers as the inventor of the Washington Lyon Steam Disinfector, which entirely revolutionised the inefficient and unsatisfactory methods of disinfection previously in use, and which has been adopted throughout the world. The deceased gentleman had reached the ripe age of eighty-two, and the sanitary world will be the poorer for his loss.

Dr. Seaton, M.O.H. for the County of Surrey, makes reference in his annual report to the unsatisfactory position of a man holding the dual offices of Surveyor and Inspector of Nuisances. He does not hesitate to affirm that where this condition prevails proper sanitary adminstration cannot be carried out.

SANITATION OF COW-BYRES.

In his tenth annual report Dr. Nasmyth, the Medical Officer for the County of Fife, makes certain suggestions which have become necessary through recent legislation, and by the new Dairy Order of 1899. The additions to the regulations adopted in 1897 he would strongly recommend are :—

(1) Separate and distinct arrangements for the cleansing and scalding of dairy utensils apart from the domestic washing arrangements, so as to exclude the possibility of infected clothing being brought into contact with dairy utensils and milk supply.

(2) Provisions for lighting. This should not be a mere abstract suggestion, but should be a concrete quantity. It is now well recognised that light is as necessary for the health of cows as it is for human beings. It is not a faddist's theory. Mr. Speir, of Newton Farm, an authority on dairying and a practical dairyman, advises that there should be two square feet for every cow.

(3) Provisions for ventilation. These should also be definite and specified, so many square inches for inlet and so many for outlet per cow. Four square inches for each would be a fair allowance. This could be effected by having an ordinary six-inch drain pipe through the wall at the cow's head, sloping upwards. The expenses of this would be very small, and provided these were kept open and not closed with wisps of straw, the question of a large cubic air space would be of less consequence. The proviso, however, is absolute. Outlets should be provided at the ridge in the same proportion. Mr. Speir, in his most valuable suggestions, emphasises these points we all are at one about, viz.:— Impermeable floors, cement in preference ; cement dados 6ft. high round the byres ; ample use of lime-wash above the dados. Mr. Speir further advises as a most important point, the construction of the gutter behind the cows, which should be 2ft. wide, 6in. deep next the cow, and 4in. next the footway, with a fall of half an inch longitudinally for each cow, and half an inch laterally in the gutter to the footway.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2198.—Sewage Disposal Scheme for Hospital.—"W. S." writes :—"In my district we are at the present time well forward with the reconstruction of an infectious diseases hospital. The institution stands within an enclosed area of 2½ acres, upon rising ground, and will, when finished, accommodate about forty people. The disposal of sewage is a somewhat difficult problem. Hitherto a cesspool has been used, but as the overflow sometimes gets into a stream which runs close by, the method of sewage disposal must be improved. An intimation of the best and most practical system of sewage treatment for the institution in question by some of your readers or yourself will be deemed a favour."

Answer.—The sewage may be treated on bacteria beds, coarse and fine, and with or without previous treatment in a detritus tank, or it may be treated by a septic tank and subsequently on bacteria beds. The querist should obtain Thudichum's "Bacterial Methods of Sewage Purification," price 1s. 3d. ; Martin's "Purification of Sewage by Bacteria," price 6½d. ; and Adam's "Local Government Board's Requirements as to Sewage Schemes," price 2s. 6d., obtainable from the office of this journal, post free at the prices named, from which he should be able to decide upon a satisfactory scheme for the purification of the sewage of the hospital.

2199.—Cleansing Houses of Persons in Receipt of Parish Relief.—"Assistant" writes :—"With reference to your answer to query 2171, page 373, in which you advise that the Relieving Officer should defray the cost of cleansing the houses of infirm persons in receipt of parish relief, and who are unable to do the work themselves, or that the Local Authority might do the work and charge the cost to the rates. May I ask if notice could not legally be served on the owner compelling him to limewash ?"

Answer.—There is no doubt that the Local Authority may serve notice upon the owner to limewash the premises, &c., either under Sec. 46 of the Act of 1875, or under Sec. 5 of the Infectious Disease (Prevention) Act, 1890, and we were fully aware of this when we wrote our former reply. But the owner would be entitled to object to such a notice, and could, in our opinion, successfully defend the Authority's requirements. It would, moreover, in our opinion, be unreasonable to cast the duty, under the circumstances in question, upon the owner, as he is not in default.

2200.—Quantities : Book on for Road-making and Sewer Construction.—"Surveyor" writes :—"I should be glad if you could advise me of a good book on taking out quantities, preparing bills and measuring for work on road-making and sewer construction."

Answer.—The querist will find Bartlett's "Quantities : Road-making and Sewer Construction for the use of Surveyors, Municipal Engineers, &c.," price 7s. 6d., the book he requires. By its aid every Surveyor should be enabled to get out quantities, &c., in a methodical and trustworthy manner. The book may be obtained from the Sanitary Publishing Company, 5, Fetter-lane, London, E.C., post free at the published price.

2201.—Street Watering and Dust Carts : Opinions Required. — "Surveyor" writes : — "Will any Municipal Engineer give his experience in watering streets by means of a perforated pipe laid along each kerb line ? Is there any better method of watering than by a water cart ? What is the usual form of dust cart for any street sweepings ? As the querist is at the Antipodes, full information is asked for."

Answer.—We invite the opinion of Municipal Engineers to the question, and shall be glad to publish their communications. Our advice to any engineer who contemplates recommending any such system as the laying of perforated pipes alongside the kerb is "Don't." The system has been tried in one or two places and was found very unsatisfactory, and the cost prohibitive. No system has been found so satisfactory as the employment of a water van drawn by a horse or motor. The ordinary "tip cart" with high sides, and provided with a tarpaulin, or light metal cover, to prevent the dust from being blown off the cart, is in most favour, and is to be generally recommended. Messrs. Wm. Glover and Sons, Limited, Warwick, makers of water vans and dust carts, will, on application, send the querist their illustrated lists of carts, vans, &c., used by municipal bodies. We also advise the querist to obtain Boulnois' "Municipal and Sanitary Engineers' Hand-book," price 15s., and Maxwell's "Removal and Disposal of Town Refuse," price 15s., post free from the office of this journal at the prices named. Cardew's "Australian Municipal Pocket-book of Engineering for the Use of Laymen" will also be found useful.

2202.—Ventilation of Sewers by Electric Light Standards. —"M. G." writes :—"I should be glad to have your opinion as to the practicability of the idea which has occurred to me of ventilating public sewers by means of electric light standards where such exist alongside highways, and as to whether it is worth patenting. I enclose sketch.

Answer.—The system of ventilating sewers by isolated iron standards, such as lamp columns, iron ventilating shafts such as those manufactured by Messrs. Ham, Baker, and Co., shown in our advertising pages every week, is an old one and at the same time a good one. But in the sketch submitted by the querist there is nothing original, and consequently nothing to patent, and we could not advise the querist to spend any money in the endeavour to obtain a patent.

2203.—Tuberculosis in Animals : Book Recommended.— "G. W." writes :—"What is meant by pseudo-tuberculosis ? In what part of the carcase would you look for evidence of the disease ? Would the carcase of an animal so affected be fit for food ?"

Answer.—The querist should obtain Vacher's "Food Inspector's Handbook," price 3s. 6d., post free from the Sanitary Publishing Company, 5, Fetter-lane, London, E.C., from which the desired information may be obtained.

2204.—Testing House Drains by Private Request.—"Another Inspector" writes :—"The answer to Query 2183, in your issue of May 2nd, is definite so far as it goes ; but should a person, either in writing or verbally, state that his house is in an unsanitary condition, *i.e.*, that there is a bad smell in the house would an Inspector be bound to test if he was morally certain that the premises were in a sanitary condition ? I have not overlooked the General Orders."

Answer.—An Inspector would not be justified in refusing to

THE STUDENT'S GUIDE to SUCCESS

IN SANITARY INSPECTORS' EXAMINATIONS.

By MATTHEW CHAPMAN, Sanitary Inspector, Grimsby.

This little work conveys in a compact and concise form a wealth of useful information to the student. It not only gives model questions, but explains the best mode of answering, and when necessary, of illustrating them. As a supplementary volume to the standard text-books, such as Reid's and Taylor's, it will be found invaluable, as it shows at a glance how to put the knowledge gained from these works into answers suitable for examiners.

ALTHOUGH NEWLY PUBLISHED, THE DEMAND FOR THIS WORK IS ALREADY CONSIDERABLE.

THE SANITARY PUBLISHING CO., LTD.,

5, FETTER LANE, LONDON, E.C.

inspect a dwelling-house after receiving a complaint as to the existence of a nuisance therein on such grounds as being "morally certain" that the premises are in a sanitary condition. His duty, as prescribed by the General Orders of the Local Government Board of the 23rd March, 1891, relating to the duties of an Inspector of Nuisances, is—"On receiving notice of the existence of any nuisance, to visit the spot as early as practicable and inquire into such alleged nuisance." Neither an owner nor an occupier is enabled to demand from, or dictate to, the Inspector that he shall test the drains of any house. The determination as to whether it is necessary to test the drains by the smoke, chemical, or hydraulic test is one which is in the absolute discretion of the Inspector. If there is any reason to suspect that the drainage is imperfect, the Inspector would be guilty of dereliction of duty if he failed to take such steps as were necessary to discover the defects, and to do this the drains should be tested in an approved and skilful manner. A vigilant Inspector will always, while on duty, carry in his pocket one or more of Kingzett's drain testers, as manufactured by the Sanitas Company, Limited, and make a preliminary test of a drain by inserting one of these therein, from the use of which a reliable index can be formed of its soundness or otherwise. He should subsequently, if any defect is noticeable, locate the defect by the use of the smoke machine. We always advise that the drainage of all houses wherein a case of infectious disease has occurred be thoroughly tested with the smoke machine.

2205.—Female Sanitary Inspectorships: How to Qualify For.—"M. D." writes:—"Will you allow me to point out a slight error in your reply to 'K. B.,' Query 2194 (page 438), May 16th. You tell your querist that 'she should obtain by examination the certificate of the Sanitary Institute for Sanitary Inspectors.' The Institute only *trains* candidates for the office of Sanitary Inspector; its certificate does not qualify for the office. 'K. B.' must obtain the certificate of the Sanitary Inspectors' Examination Board, concerning which and the course of training precedent to examination she can obtain information from the honorary secretary of the Board, No. 1 Adelaide-buildings, London Bridge, E.C."

Answer.—We are obliged to our esteemed correspondent for his communication. He is, however, under a misapprehension, and has confused the examination held by the Sanitary Inspectors' Examination Board, whose certificate is required for candidates for an inspectorship in London, and where it is alone recognised at present, as applying to provincial Inspectors also. Our former answer had reference to provincial Inspectors based on the requirements of the querist, and was quite correct. The certificate of the Sanitary Institute is practically the only certificate recognised by Sanitary Authorities outside the metropolis, as a reference to their advertisements for Inspectors will show. This certificate is, moreover, distinctly a certificate of competency of the examinee that he is qualified to discharge the duties of an Inspector of Nuisances, and our correspondent is also in error in stating that such certificate does not qualify for the office, and that the Sanitary Institute only trains candidates for the office. The Sanitary Inspectors' Examination Board do not conduct examinations for Sanitary Inspectors under the Public Health Act, 1875, but only under the Public Health (London) Act, 1891.

2206.—Building Bye-laws: Return Wall.—"Surveyor" writes: "In a plan submitted to an Urban Authority, a party wall is shown 9in. in thickness and 30ft. in length. This party wall has a return wall of the full thickness toothed into it. Does this comply with the bye-laws as to lateral support?"

Answer.—The return wall, so far as we can determine, is carried up to the top of the topmost storey. If this be the case, the plan complies with the bye-laws.

2207.—Building Plans Deposited for Approval Copied by a Councillor.—"R. J." writes: "Has a Councillor the right to take tracings of plans submitted to the Council by architects and builders, and if tracings are taken, has the owner of the plans any power in the matter?"

Answer.—A Councillor has no right to take such tracings. His conduct is highly improper. The plans are not the property of the Council to permit such a licence being taken. But how does the Councillor obtain access to the plans? The Surveyor should refuse him permission to do so while they are in his possession without the authority of his Council, and the latter are not enabled to give such authority without committing a serious breach of trust. Any architect, &c., aggrieved should communicate with the Local Government Board.

2208.—Officer's Duties: Whether Entitled to Extra Payment.—"C. S. I." writes:—"I had occasion some time ago to summon two persons for non-compliance with notice to abate nuisances on their premises. The Medical Officer of Health was called to give evidence, and we got a conviction. Can the Medical Officer of Health charge for giving evidence in Court, seeing that he is paid by the Authority a fixed salary? I may say that he is a part-time official."

Answer.—As to whether the Medical Officer is entitled to payment from the Local Authority for attending the police-court to give evidence, this will depend upon the terms of his appointment. Unless it is specially provided that he is to be so paid we do not think that he will be entitled to charge a fee for attendance. If, however, his fees are allowed by the magistrates in awarding costs he will be entitled to receive such.

J. & M CRAIG, Ltd., KILMARNOCK

INFECTIOUS DISEASES, DISINFECTION, VENTILATION.

By W. Arnold Evans, M.D., Medical Officer of Health, Bradford.

The following is the second of a series of ten lectures to Sanitary Officers and others, organised by a Joint Committee of the West Riding County Council, and the County Boroughs of Leeds, Bradford, Huddersfield, and Halifax, along with the Yorkshire College and the Sanitary Institute.

The lecture was delivered at the Philosophical Hall, Leeds, before a large audience of some 300 Sanitary Inspectors and others. Councillor E. E. Lawson, Chairman of the Leeds Sanitary Committee, occupied the chair, and introduced the lecturer, who spoke as follows, illustrating his remarks by numerous lantern slides :—

Mr. Chairman, Ladies and Gentlemen:

Although the first part of my lecture is entitled "Infectious Diseases," it is not my intention to speak of all those diseases which we know to be infective in their nature. To do this in the time we have at our disposal this afternoon would be impossible. Most of my remarks will be devoted to the consideration of those duties which are to be carried out by the Sanitary Inspector, in reference to infectious diseases scheduled under the "Infectious Diseases" Notification Act, or to any other concerning which he may receive instructions from his Medical Officer of Health.

Now, it is a matter of common knowledge that the onset of an attack of most of the commonly recognised infectious diseases is characterised by "fever," *i.e.*, a rise in the bodily temperature. The person attacked is the subject of several uncomfortable symptoms, and the temperature of his body is raised. In health the temperature of the body is about 98·5 Fah., and any rise over this figure constitutes a condition of "fever," which state of body being common to almost all the infectious diseases had led to the application of the word "fever" as a sufficient description of such disorders. Hence the two expressions "fever" and "infectious diseases" are commonly regarded as synonymous.

The first stage in the course of a fever is the *infection* or the time at which the germ of the disease enters the body. In some cases this epoch can be definitely fixed; when, for instance, a person has visited a friend or relative known to be suffering from small-pox, and in about fourteen days afterwards sickens of the disease. In most cases, however, the time of infection is not found without further and sometimes laborious inquiry. The manner in which the infective germ has gained access to the body varies considerably; infection may take place through an abrasion of the skin as in erysipelas, or by means of the lungs as in typhus fever, or by means of food or water, *e.g.*, enteric fever or cholera. But although a person may receive the germs of fever into his system, it does not necessarily follow that he will suffer from an attack of the disorder commonly produced by such infection. In the subsequent changes taking place in the organs of the body in which the infection has been received, or in the blood, the germs may undergo disintegration, and produce no untoward result. If, however, the germs gain the mastery, and produce an attack of the disease, the characteristic symptoms do not show themselves at once. The period between the date of infection and the onset of the disease is called the period of "incubation," and varies considerably in different diseases. In some of the fevers, the period of incubation varies within narrow limits, *e.g.*, small-pox, which has an incubation period of about fourteen days; for out of about 2000 cases of small-pox which at one time or another have come under my notice, I have not known the incubation period to be less than twelve or more than fifteen days. In other disorders the incubation period may vary within wide limits, *e.g.*, enteric fever, in which it is usually about a fortnight, but may vary from a few days to three weeks. For a reason to which I shall presently refer, it is important to know as accurately as possible the incubation period of those affections against which we wish to adopt measures of prevention.

Well, the incubation period having been completed, we next come to the onset of the disorder, which in most cases is sudden, and marked by a rise of temperature and other symptoms such as shiverings, convulsions, or a sore throat and enlargement of glands. In some instances, however, the onset is insidious, the patient being scarcely able to fix the day upon which his illness commenced, and can only say that he has been ailing more or less for a week or so; such is commonly given as the history of the onset in a case of enteric fever. The fever subsequently passes through two more stages, which we shall call the *height* and the *decline* of the fever; during the first of these the temperature remains high, but may last only a few hours, as in the case of pneumonia, or a considerably longer period, as in some cases of enteric fever; the decline of the fever may be sudden, when ailment is said to end by crisis, as in typhus fever, or of long duration, when it is said to end by lysis, *e.g.*, typhoid fever. But even now the end of the illness is not reached, for there is the period of convalescence to follow, which may be of short or long duration; in fact, in some diseases, such as influenza, great prostration and mental depression may follow, the patient may not make a complete recovery for eighteen months or two years.

The most common infectious diseases with which you are likely to be brought into contact are those scheduled in the Infectious Disease Notification Act, viz., scarlet fever, diphtheria, cholera, small-pox, erysipelas, puerperal fever, relapsing continued typhus, and enteric fever. In addition to these I must add tuberculosis, for we now know that this disease is spread by infection, and that certain preventive measures may be taken to control it. There is also another disease which has lately invaded some of the British ports, viz., *plague*, and although it has not so far succeeded in gaining a foothold in this country, it seems to have permanently established itself in India and South Africa, so that Inspectors of Port Sanitary Authorities should be on their guard in reference to suspicious cases of disease occurring on board ships from these places.

I will now touch as briefly as I can upon the various diseases included in the list that I have given to you.

Scarlet fever.—In scarlet fever the incubation period varies from one to seven days, but it is usually about two or three. Cases of this disease are not infrequently overlooked, owing to the fact that some are extremely mild and no doctor has to be in attendance; so that in making your inquiry as to the cause it is well to remember that the case reported may not be the first one in the district, consequently you should inquire if any other children in the vicinity have been laid up with a sore throat, or are mixing with other children when their skin is in a peeling condition. Scarlet fever is sometimes spread by means of milk; in fact, an infected milk supply is a well-known cause of a sudden epidemic; it may, therefore, become your duty to make a careful investigation of the surroundings of the dairy from which the milk is derived, and of any source from which the milk may have been supplied. In order to prevent the spread of the disease it is necessary to insist upon isolation of the patient, and if this cannot be carried out at home removal to the fever hospital should be effected.

Sometimes the disease is spread by infected per-

sons attending a particular school, and if it be found impossible to exclude from school attendance the actual offenders, it may be necessary to close the school, more especially in the country, where the school is probably the only place where the children meet. After recovery and disinfection of the premises a period of quarantine should by imposed, during which the other persons in the house should be kept under observation and not allowed to attend school. In my practice I fix this period of quarantine at seven days, which I think is little enough.

Diphtheria.—This disease, which some years ago was chiefly confined to country districts, is now exceedingly common in the towns, and in two of the largest county boroughs in Yorkshire has of late become rife. Why this should be so is difficult to explain. The incubation period is somewhat uncertain, and ranges between two days and a week. It is one of those diseases which, like scarlet fever, is liable to escape detection when mild, and to be considered as nothing more than an ordinary sore throat. So that in making your inquiry it is necessary to ascertain the school attendance, and find out whether many children are away from a similar cause. Many cases of apparently slight sore throat are true cases of diphtheria and spread the disease widely.

It may be spread by milk, so that the same inquiry must be made as in the case of scarlet fever. You should also carefully inspect the drainage, for not a few outbursts of diphtheria have been attributed to bad drainage. It is well, if possible, to have cases of diphtheria isolated in hospital, particularly if there be any children in the infected house. The quarantine period is twelve days.

Enteric fever.—The incubation period of enteric fever varies from a few days to three weeks, but is usually about a fortnight. The three matters to which you should give special attention in your inspection as to an outbreak of this disease are water, milk, and drainage, and latterly a not infrequent source of infection has been discovered in shellfish which have been fed in sewage polluted waters. In country districts the water is the most common cause of enteric fever; a spring or small watercourse fouled with the excreta from any person suffering from typhoid fever will cause a sudden and serious outbreak amongst those who take the water, *e.g.*, Kildwick outbreak. Typhoid fever is one of those diseases which are spread chiefly by negligence on the part of those responsible for the destruction of the excreta from a sick person. You must insist upon the greatest care being taken as to the disposal of both liquid and solid excreta of a person suffering from enteric fever; directly the stools are passed they should be placed in disinfectants, and the utmost cleanliness must be observed by persons brought into contact with the infected person. The ultimate disposal of the excreta is a matter of great importance. If there is a water-closet in the house they should be put into it after preliminary disinfection, and so disposed of. Should there only be a privy midden, I think it would be safer to bury the typhoid dejecta. Natural disinfection takes place in the earth, and provided the noxious material is not so buried as to pollute some water supply, no harm is done. On no account leave the excreta from a person suffering from enteric about the premises, but let it be disposed of quickly; the dried material from typhoid patients is the potent source of infection.

Typhus fever.—The incubation period of this disease varies from three or four days to three weeks; but for practical purposes you may consider it to be about twelve days. With the exception of an occasional outburst in some of the squalid districts of a great city, typhus fever is now seldom heard of; and in those cities, *e.g.*, Liverpool, Dublin, and Edinburgh, where it used to be common, it has now become much less so. The cause of this disorder is overcrowding and destitution. You will generally find that this kind of case occurs in a filthy house; and if you happen to see it amongst the members of a clean and well-ordered family, the great probability is that such people have been infected by personal contact with the filthy. Under insanitary conditions typhus fever is exceedingly infectious, but cases isolated in a well-ventilated and well-lighted hospital ward do not frequently infect persons who are engaged to attend them. Should cases of this kind come under your notice, you should take means to have them isolated in a hospital; and considering the class of people amongst which such cases occur, you will scarcely have any difficulty in effecting their removal. Should, however, treatment be undertaken at home, the principal consideration is free ventilation. It is difficult to lay down a rule as to when the period of infection is over, so that in fixing the period of quarantine you must be guided by medical advice.

Small-pox.—The period of incubation varies between twelve and fifteen days. When inquiring into a case of small-pox, you must remember that the disease does not arise out of ordinary filth conditions, as epidemic diarrhœa does, but that each case of small-pox arises from some pre-existing case, and that the infection has been conveyed by some infected person or thing. You should inquire as to whether any other suspicious case has been heard of in the yard or court; find out where the infected person has lately been visiting; if his work takes him away from home, or whether he has had visitors from an infected town. All these points are very important. The means that you should adopt to prevent the spread of the disease are (1) the isolation of the case in hospital, and there is usually no difficulty about this. (2) Disinfection of the premises. (3) Keep under observation for not less than eighteen days all those who have been in contact with the infected person, and should you find any of them sicken, report the matter at once to the Medical Officer. (4) Persuade all persons in the house and all "contact" to be vaccinated or re-vaccinated, as the case may be, at once. The person is free from infection directly all the scabs have fallen from his skin.

Measles and whooping-cough.—Although not often included in the list of notifiable diseases, these two complaints are responsible for more deaths than are caused by all the other diseases of which I have spoken. It is commonly thought by a large number of people that all children must at some time or other have an attack of measles and whooping-cough, and that the sooner they get it over the better. Nothing could be further from the truth, and if more care were exercised in separating the sick from the healthy I feel sure that these diseases would not be so common. They are difficult to deal with because they are so very infectious in their early stages; if, however, the first cases in a district can be secured and isolated, and measures of disinfection thoroughly carried out, the spread of the disease can sometimes be arrested, but in many instances it is found necessary to close a school, particularly if the pupils are very young children. Cases of measles or whooping-cough should not be considered to be free from infection for at least a month from the date of onset, and not then if any cough remain.

Tuberculosis.—Since the discovery of the micro-organism of tuberculosis, by Professor Koch in 1884, it has become more evident year after year that this disease must be included in the list of infectious disease in spite of the fact that the Local Government Board refuse their sanction to the inclusion of its most common form, viz., phthisis or consumption of the lungs, in the list of diseases of the Infectious Diseases Notification Act. Some towns have adopted a voluntary system of notification of this disease with good results. In view

of the fact that the sputa or other discharges from a person suffering from phthisis contain the living germs of the disease in abundance, it is necessary that some precaution should be taken to avoid the indiscriminate distribution of this infective matter. If the person be able to follow his employment he should use one of those portable spit cups in preference to a pocket-handkerchief, and by no means expectorate on the floor. Should, however, the case be one of advanced phthisis, the surroundings of the infected person should be chosen as carefully as his circumstances will permit; his room should be so situate as to admit of a large amount of direct sunlight, and free ventilation should be encouraged wherever possible. Any one in the early stage of phthisis should be sent to a sanatorium for the open-air treatment, not merely for the sake of isolation, but to secure the benefit of this method of treatment. Unfortunately in this country these institutions are neither numerous nor cheap, but the efforts now made by County Councils and other Public Authorities for establishing more give promise for a better state of things in the future.

Plague.—Another disease that I am bound to mention is the plague. In consequence of the commerce of this country being world-wide there has occurred already in several of the ports an outbreak of plague, but the effort of the Port Sanitary Authorities has, so far, been equal to the task of suppressing it. It is not my intention to give you a clinical description of a case, but only to point out that the more insanitary the condition of any town into which it may be introduced the greater is the difficulty of getting rid of it. I will merely mention the case of Bombay, where the disease seems to have permanently established itself, and of Cape Town, which is apparently attaining the same unenviable position.

We may now consider the manner in which infectious diseases are spread. There used to be a popular distinction between diseases that were contagious, *i.e.*, spread by personal contact, and those that were infectious, *i.e.*, conveyed through the air without any personal contact. In this sense, as pointed out by a recent writer, "small-pox would be called an infectious, and anthrax a contagious disease; for the former is usually conveyed through the air, and the latter by infected articles. But small-pox can infect by direct contact, as in the old preventive treatment of variolation, and anthrax may be conveyed by the air, as in some forms of wool-sorters' disease." The distinction between "infection" and "contagion" thus breaks down, and perhaps we had better give it up altogether. Nevertheless we must not lose sight of the fact that some diseases are generally conveyed through the air, and others by direct or indirect contact.

It is acknowledged by all that diseases of the infective order are produced by micro-organisms, and that for each disease there exists a specific microbe, although in some diseases it may not have been discovered. The methods by which such organisms enter the body are:—

(1) *Pulmonary infection.*—The bacilli, or spores, are inspired with the breath, and enter the body through the delicate mucous lining of the lungs; as instances of this method of infection I may name diphtheria, influenza, and the pulmonary form of tuberculosis.

(2) *Intestinal infection.*—In which the organisms are swallowed with food, dust, or water, *e.g.*, cholera, enteric fever.

(3) *Inoculation* through a wounded or unwounded surface of the skin, as in the case of erysipelas, hydrophobia, or anthrax.

(4) *Infection by means* of infected articles in which the manner of entrance of the virus into the body is not precisely understood, *e.g.*, leprosy and pneumonia.

Now, since micro-organisms are carried through the air, and so infect at a considerable distance, it is important that infected articles, *e.g.*, soiled linen, should not be allowed to become dry until they have been disinfected. All soiled blankets, &c., which have been in contact with a person suffering from an infectious disease, whether in a private house or a hospital should be placed in a tank of disinfectant solution and kept there till washed. The cholera bacillus, however, when deprived of moisture, rapidly dies, so that this disease is not transmitted through the air.

(To be continued.)

SANITARY DANGERS IN FLATS AND TENEMENT HOUSES.

Some remarks under this heading occur in the annual report of Dr. Clothier, Medical Officer of Health for Hornsey. He says:—"Unless great care is taken in seeing that proper air space, both back and front, is given, and no overcrowding allowed, this altered style of building will tend to become a danger to the public health. The object of this style of house is to admit of the crowding of more people into the same, or even less, cubic space than has hitherto been considered necessary, and this of itself, if carried beyond a certain point, constitutes a public danger, more particularly as regards infectious, tuberculous, and respiratory diseases. Overcrowding may apply to blocks of houses being too near each other—that is to say, not having sufficient air space between them—to houses having too many tenements, and to rooms being too small for the number of persons living in them. As regards these tenement houses, some have been newly erected, some are situated over shops, and others are the result of alterations of houses already built, the alteration always consisting in making so-called separate provision for more families than could be accommodated before the alteration. . . In these smaller houses the sanitary arrangements are quite distinct, and the dust-bins can be kept outside in the gardens or back courts. In houses containing, however, more than two tenements, the dust-bins are not always kept outside, as should be the case, and, in fact, in some of these houses no proper place has been provided for the bins, which are either placed in the houses or passages, and thus constitute a nuisance. There is one advantage which these tenement houses have, and that is that the sanitary dust-bins provided must be small, and consequently have to be frequently emptied. The very fact, however, which necessitates their being small, namely, because they have often to be carried through the houses and down the common stairs, may in itself constitute a bad nuisance in the shape of smells being given off whilst the bins are being carried down and emptied. Another feature in some of these houses not to be recommended is the fact that the larders are not ventilated from the outside, but open directly into the kitchens. A larder so situated is not a proper place in which to put milk, fruit, and vegetables, especially during the hot weather. . . . One point which will have to be considered is the course of action to be adopted on the outbreak of dangerous infectious disease in a tenement house. It is quite certain that susceptible people living in such a house will stand a much greater chance of catching the disease than if they lived in entirely separate houses, and this points to the greater necessity of isolating first cases as soon as possible, which can only be effectively done by removal to hospital. Another very serious question arises, namely:—Supposing that for some reason or other the patient be not removed, but isolated so far as can be done at home, is the tenement where the patient lives, or the whole house to be considered infectious, and are children who live in the other tenements, and have very probably been in contact with the patient, to be excluded from school as well as those living in the tenement where the disease actually exists?

INSANITARY BAKERIES IN INDIA.

A REPORT by Major R. H. Firth, late Sanitary Officer Rawal Pindi district (now Professor of Hygiene at the Army Medical School, Netley), deals, among other matters, with insanitary bakeries. His remarks are sufficiently interesting to be reproduced in detail. The bakeries, he says, may be divided into three groups, (*a*) those belonging to the commissariat, (*b*) those owned by Europeans, and (*c*) those owned by natives in the bazaars. The first named supply all ration bread. I have inspected all these bakeries in the district, and found little to criticise, beyond the quality of the flour. This, at times, has been somewhat indifferent, notably in the Murree hills during the autumn of 1899, when samples were examined by me from Kalabagh and found to be extremely faulty. As a result of my representations, that stock of flour was destroyed.

The chief complaint against commissariat bread, especially in the hot season, is that it is unduly acid or sour. This depends partly on the use of dirty flour or the access of dust to a flour originally clean, and partly to difficulties dependent on temperature, whereby fermentation proceeds too rapidly or too far. In the Government bakeries I have invariably found all kneading troughs and ferment clean. The ferment, or so-called yeast, used in the commissariat bakeries has been repeatedly examined and found free from objection. It is made by adding one pound of crushed malt to a hot infusion of hops. The malt comes from the Murree brewery and the hops from Kashmir. I am inclined to think that this ferment tends to make a rather dark and somewhat bitter bread.

The second class of bakeries, or the private ones owned and managed by Europeans, are limited in number and practically exist only in Rawal Pindi. As a rule they are well kept and present no grave sanitary objections, except that they all employ the native process for obtaining a ferment. Under the supervision of managers like Ahrens and Cumper, the risks attending the preparation of this leaven in these private bakeries is reduced to a minimum, and the bakeries themselves and the bread turned out beyond criticism.

The third class of bakeries are all owned by natives and invariably situated in the bazaars. Without exception they are dark, dismal hovels, having no other air vent than the door. If by chance a window does exist this is invariably occluded by rags or canvas. Nearly all the work is done and the storage accommodation placed on the floor.

These native bakeries have a sanitary importance in that they as a class are the chief source of supply of the many cakes and buns so much in demand among the younger soldiers. Further, to a large extent, the various coffee shops, temperance rooms, regimental and religious institutes, such as "homes" and prayer rooms, are supplied with bread and cakes from bakeries of this kind. In this district there are certain notable exceptions; thus the Sussex Regiment at Sialkot has its own bakery in the lines, so have the 4th Dragoon Guards at Pindi. Both are quite clean and satisfactory. The contract baker to the latter regiment is also baker to the Somerset Light Infantry. In all these bakeries, whether in lines or not, the leaven, or "khamir," employed is prepared after the native method, and not such as is used in the commissariat bakeries out here or in the bakeries at home. Yeast, by this I mean true yeast, is unknown among bakers in this district, at least it is never used.

In the above-mentioned native process for obtaining a leaven the active agent is sour butter milk. The procedure is simple. A certain amount of this sour butter milk is mixed with flour, and to that is added a small quantity of "massala." The whole is tied up in a rag and placed in a warm dark corner of the bakery, often stowed away on a rafter in the roof. Twelve to fifteen hours suffice to secure active fermentation of the mass, which now constitutes the baker's stock of so-called yeast, or "khamir," or ferment. A portion of this is next worked up with flour into a dough, which is the equivalent of the English baker's "sponge," and from this again the "dough" or final article is made. The theory underlying the English and native methods is identical, the difference lies merely in the source of the ferment; in one it is either the yeast plant or the organic ferment present in malt, in the other it is from the cold but much decomposed and acid butter milk. The addition of "massala," to which the native baker attaches so much importance and mystery, is merely a relic of trade superstition. The composition of this "massala" is regarded by most native bakers as a trade secret. From my inquiries I find that the following constituents enter into the composition of most bakers' "massala":—Gum mastiche, myrrh, powdered cloves, powdered nutmegs, coriander seed, cardamoms, saffron, cinnamon, powdered liquorice root, seeds of the lotus, pop corns or parched maize, and a kind of coarse meerschaum which comes from the sea coast and called *samunder sukh*. Except as a means of introducing saprophytic organisms, if not worse, to the mixture of flour and sour butter milk, these ingredients of the "massala" play no important part in the leavening process.

As to the butter milk I have examined many samples. The same is invariably to be found in a small earthenware ghurra, stuck away in some out-of-the-way corner. Bacteriologically, these samples defy description, for they usually are nothing but a mass of saprophytic organisms. I have never isolated either the B. typhosus or the cholera vibrio from any of these samples, but on two occasions have readily obtained B. coli and once the B. enteriditis sporogenes. Having regard to the primary origin in most cases of this sour and fermenting butter milk from any casual bazaar or village source, and to its subsequent storage and treatment in dirty houses, it requires no technical knowledge to appreciate the possibilities of evil from this pivot on which the whole bazaar baker's business works.

I am not disposed to lay undue stress on the unsatisfactory nature of this "khamir" of the native bakeries, nor do I think that there is any sound evidence forthcoming that any serious disease results to the troops from its employment. But, what I wish to emphasise is the need of the greatest scrutiny and supervision of this material. To many officers its employment and nature is quite unknown. My experience goes to show that the better class native bakers and those holding contracts with corps, are fully alive to the need of care in the selection of the source from whence they get this sour milk. Of course they realise nothing of the reasons why it should be obtained only from the purest of milk; still they try, I think, to get it from sanitary sources. It will be a very difficult matter to get these men to discard it, and there is no denying that in good hands and under sanitary conditions, this native-made leaven produces a whiter looking and sweeter tasting bread than that made with the leaven or so-called yeast of the commissariat bakeries.

Another question in respect of insanitary bakeries has interested me. It is this: What is the possible effect of using foul or dirty ingredients in bread making upon the bread or cake consumer? Many are inclined to think that, however filthy the bakery, however contaminated the flour or the ingredients of the leaven or dough may be, all will be right by the mere process of baking in an oven which destroys those organisms now recognised as lying at the root of most diseased conditions. This question arose some time ago in England, and certain investigations by Drs. Waldo and Walsh indicated that the contention that baking sterilises the loaf or cake rests on mere assumption. As the conditions which per-

tain in an Indian bakery are peculiar and differ materially from those in England, I instituted a series of experiments to elucidate the question raised.

There are obviously two ways in which a loaf may convey specific disease organisms to the consumer, viz.: —(1) By organisms lodging on the crust from contamination in the bakery or in transit; (2) by organisms which possibly escape destruction inside the loaf during baking.

The possibilities of contaminating the crust during storage or transit are too patent. The remedy must be either by elaborate precautions which are impracticable, or re-sterilisation of the crust by putting in a hot oven for a short while before use. This is a refinement quite beyond ordinary routine.

The possibility of the survival of organisms in the interior of a baked loaf or cake is more complex and involves a consideration of temperature. From a series of experiments made by myself, I find that the average maximum temperature in the middle of an ordinary Indian loaf when baked in the common oven of an Indian bakery varies from 84 deg. Cent. to 95 deg. Cent. The loaf does not remain more than 40 min. in the oven, and the increase of temperature from an average initial point of 25 deg. Cent. averages 7 deg. for each 10 min. of time, so that the maximum temperature of from 84 deg. Cent. to 95 deg. Cent. is only reached and maintained in the last few minutes of the loaf's stay in the oven, and that for the first 40 min. the maximum temperature inside the loaf is not more than 50 deg. Cent. Few bacteria and their spores are destroyed by an exposure to the above-mentioned temperatures, and on theoretical grounds it is safe to assume that bacteria and their spores are not necessarily destroyed inside a loaf by baking. So much for theory, now for facts.

To obtain facts, a series of gelatine tubes were seeded direct from loaves as these left the oven by removing a small piece of bread from the centre of the loaf with a sterilised knife, rapidly crumbling the piece up and dropping the *débris* into the tube of liquefied gelatine; from these, plates were set. In this manner, twenty-three loaves were examined from different places, and in all seventeen distinct varieties of bacteria and moulds were found, none, however, being pathogenic organisms.

These results clearly showed that it is possible for organisms to survive even the process of baking, though the number of positive results is smaller than I expected. As a control, I artificially infected a dough mass with a fresh culture of M. prodigiosus, which by reason of its colour is readily recognised. From this dough two loaves were moulded, and then baked in the usual way. Of ten cultures set from each, one group yielded 3, 0, 0, 1, 0, 4, 2, 0, 0, and 1, the other 0, 0, 0, 0, 2, 0, 1, 3, 0, 0, colonies of M. prodigiosus.

I have spent much time over this inquiry, as it appeared to me of great practical importance. Without doubting that the conditions in the centre of most loaves are such that the greater number of organisms present in the unbaked mass are destroyed, still the fact that certain non-pathogenic organisms or their spores can be demonstrated as capable of surviving the baking process in the centre of an ordinary loaf, suggests the argument by analogy that pathogenic bacteria or their spores may also safely survive, and that they do so is extremely probable.

The new refuse destructor, which has been erected on a site contiguous to the electric light works in Moss-lane, Morecambe, has been opened, and is now running for testing purposes—a month being allowed for this purpose. The contract price was £5000, and the contractors are Messrs. Stirling and Hughes, Liverpool. With the aid of the destructor additional power will be secured for generating electric current, and a motor will be worked in addition.

SWEEPING UP THE MICROBES.

Mr. Elmer W. Firth, a Fellow of Columbia University, has been granted the degree of Doctor of Philosophy because he has proved the common ordinary broom to be a great menace to the public health. Mr. Firth followed the trial of the broom all over Greater New York, and found that its use whisks up into the air countless millions of microbes which otherwise would lie quietly on the ground out of the reach of the human being. Armed with a machine for collecting the germs, Mr. Firth went into court-rooms, school-rooms, churches, railway trains, horse cars, ferry-boats, &c., and procured samples of the air in each, in most cases before and after sweeping.

These samples of air he took home to his laboratory and under the microscope he counted the germs. The result was, to say the least, remarkable, and points a significant moral in the matter of public sanitation. For instance, on a single fibre one and a-half inches long, taken from the cocoa matting of a train, Mr. Firth counted nearly two million bacteria. It was an inner fibre, however. On an outer fibre, which had long been exposed to the feet of the multitude, there were found between three and four million germs.

In an ordinary room previous to sweeping the investigator found an average of 600 germs per cubic metre; after dry sweeping he found an average of 18,000 germs per cubic metre, showing that sweeping increased the number of bacteria by 30 times. In a well-known church, from which Mr. Firth obtained specimens of air while the building was being "dusted," he estimated the number of micro-organisms flying through a cubic metre of air (that is, a little over a cubic yard) to be 18,139. That was the number he obtained in his cultures. Twelve hours later, when the dust had settled, his samples of air showed only 5857 organisms per cubic metre, or less than one-third the number.

The apparatus for obtaining specimens of air was concealed in a handbag, so that Mr. Firth was enabled to sit in an "L" train, or horse car, or even in church, and procure certain measured portions of the atmosphere without his near neighbour being at all aware of the fact. In the satchel was a metal cylinder, from which the air had been exhausted. This cylinder had attached to it a gauge and two stopcocks. One of the stops held a small "sand-filter." This filter stuck through a hole cut in the handbag. To secure some microbe-laden air Mr. Firth had merely to reach down and turn on the stopcock. Immediately the air rushed in through the filter, the amount of air rushing through being determined by the gauge. When a cubic metre, more or less, had been secured, the stop was cut off, the organisms having meanwhile collected in the filter. When sufficient evidence of micro-organisms had been secured, Mr. Firth made a report to the College of Physicians and Surgeons of New York. Some of his conclusions were startling.

He says carpets should be abolished from theatres, churches, and court-rooms: fibre mats should be prohibited from cars and boats; non-absorbent flooring should be used in all public places; dry sweeping should not be allowed in the presence of numbers of persons; damp cloths and wet sawdust should only be used in cleaning houses and public buildings, because the latter are settling basins for microbe-laden dust; no attempt should be made to conceal dust and dirt, as is the aim of certain absorbent floor materials now commonly used, and disinfection should not be substituted for the removal of accumulated dirt.

"Numerous investigations," says Mr. Firth, "have demonstrated the presence of micro-organisms in the air everywhere and under all conditions, except over the open sea, on mountain summits, and in the Polar regions; but they are found in greatest numbers in the

vicinity of large cities, and especially where poor hygienic conditions prevail. The occurrence of bacteria in air, however, is only temporary, owing to the greater specific gravity of the organisms or of the dust particles to which they may be attached. They are foreign to air, for the reason that this medium does not afford them enough moisture and organic nutriment; but some species may retain their vitality under such unfavourable conditions for many days or even weeks, as proved by certain experiments on the communication of infectious diseases through the air.

"In many factories and workshops cleanliness receives only secondary consideration, except where dust and dirt are known to have a damaging effect on the product manufactured. At one brass-polishing establishment, where dirty windows and poor light make it necessary for workmen to hold the metal close to the eye in order to examine the surface, I was told by an employé that three out of ten of the men employed had died of consumption within a year. The extensive trade in old rags and waste paper affords opportunity for communicating disease, and these materials are frequently handled even within the living-rooms of those that deal in them. Ulric in a rag-sorting room found two million to four million organisms per cubic metre of air.

"Dust-free air in buildings and conveyances is to be secured only by complete removal of all dirt and dust from surfaces which may be disturbed during occupation."

SOME DIFFICULTIES AFFECTING THE HOUSING PROBLEM IN BOROUGHS.

By J. H. Garratt, M.D., Medical Officer of Health, Borough of Cheltenham.

The difficulties in regard to habitation under which the poorest large families live are great. When sickness overtakes any member the conditions at once become terrible to contemplate. The houses of these large poor families are nearly always very dirty. These families occupy the small places in which they are found on account of the comparative lowness of the rent. If they went into a house which would accommodate them well, decently, and hygienically, it would cost half the income of the family to pay the rent. With reference to the division into rooms of the smallest houses I have sometimes observed that downstairs the house is divided into a little kitchen and a little front parlour. The latter being the depository of a few pathetic nick-nacks, is shut up as a sort of *sanctum sanctorum*, being only opened in all its unaired fustiness upon the rare advent of a grand visitor. It would be much better for the health and comfort of the inmates for only one good living-room to be provided in the house, instead of dividing the space as above mentioned. Where there is a little parlour downstairs, and a large family occupies the house, the room should be furnished for an additional bedroom. Sentiment, and the little pardonable pride of the wife to have a private room, generally prevents the parlour being used as a bedroom, and the space is practically lost to the house.

Generally speaking, when a man betters his position, the first thing he thinks of doing is to go into a better house; but he cannot go there until he can pay the rent. The need of going into a larger house, however, is more and more accentuated as a man becomes less and less able to do it. The larger the family grows the less rent can be afforded, and it must often happen that the reason of a family being in low water lies in some incapacity or lack of health or constitution, the only help for which lies in a better mode of living, and a better place in which to live. And how are these things to be provided? The answer to this question is the crux of the consideration. How are people who cannot pay the current rate of rental to be provided with convenient and healthy homes? It is the worst and least capable part of the populace that occupy the worst houses. This part constitutes a large class numerically. The members of this class are the worst tenants; they pay their rent irregularly; they earn irregularly. Some are naturally idle, some dissolute, some ill, some lacking in natural wit and capacity. This is the part of the populace upon which it is necessary to fix the mind in dealing with the question of the housing of the poor. It is the most unprofitable class. Inasmuch as this class is never likely to be dealt with by private enterprise, because private enterprise requires to be well paid; if any help come to it, it will come at the hands of the public, that is the public governing bodies. It is much too large and intricate a matter to be effectively dealt with by the private efforts of charitable individuals.

How can governing Coporations proceed in the matter? If they build houses with money borrowed at the greatest advantage, some to accommodate families of about eight or more persons, and some smaller, and fix the rentals at the lowest price they can afford, they will be able to supply houses of a class and convenience that cannot otherwise be got at so low a rent. These being offered for letting will instantly be taken by superior artisans and others who are earning a fair wage, and who on the whole are well able to take care of themselves. Thus a class will be benefited for whose benefit there is no urgent call. If the Corporations continue to build, they will sooner or later affect the readiness with which the other houses are let and bring down their rents, and then will begin a competition as between cheaper rents on the one hand and better houses on the other. Ultimately it may be hoped that the poorest class for whose benefit the movement was started, will get into houses a grade better than before. It is not sure that they will move at all unless the cheapest houses are compulsorily closed, or the people forced out of them. A number of persons who before paid 2s. 6d. a week for a wretched place will otherwise be inclined to stay on at 1s. 9d. When the overcrowding does not exceed the limit of 300 cubic feet of sleeping space per adult person a family cannot be forced out of a house on that score at present.

Any more direct method of re-housing the poorest of the poor is beset with the greatest difficulties. It would be a most invidious and even impossible task to pick out those that most required to be benefited. Sanitary considerations would be overwhelmed by friendly sentiment and unequal estimates of moral worth, and the worst, for whom the greatest benefits are theoretically required, would be rebuffed and offended and neglected. Human nature, and even human charity, are full of unwarranted prejudices. There are further complications in the possible ill-effect upon independence. There are many idle persons ready to lean upon any support. There are many others ready to take any unfair advantage, and in order to obtain benefits will make pretences of being worse off than they are.

Thus it is easy for Sanitary Authorities to adopt Part III. of the Housing of the Working Classes Act. It is easy for candidates for the Municipal Council to talk about improving the dwellings of the poor. But when you examine the question closely the way is obstructed, as it were, by a tangle of thorns and briars. The temper in which the matter is being treated shows a great advance in Socialistic thought, but from whatever source the idea comes of improving the dwellings of the poor, it must be practicable. The question to be answered and proved is whether the proposition for ruling bodies to provide houses for the poor be practicable; whether, in fact, the housing of the poorest can be considered apart from the raising of the standard of their moral, mental, and physical condition generally. It is a very large question and a very complex one. The whole result of public interference in providing houses for the poor seems impossible to estimate. Yet

before entering upon such a business one should know what result one is aiming at, and be able to clearly estimate the effects of one's action. It would appear as if action were being taken in some places before these points have been made plain.

ANNUAL REPORTS.

Chester (Port Sanitary Authority).—In his report for 1900, the Medical Officer of this Authority (Dr. J. Humphry Williams, Flint) states that the nature and amount of the trade carried on in the river (Dee) is much the same as previously, the foreign trade showing some diminution. During the year no notification was received, and no sickness was reported on board. The hospital at Mostyn was always ready for the immediate reception of patients, and this, together with the readiness of the Chester Fever Hospital to receive any fever patients, made the district well prepared for the appearance of any infectious cases. During the twelve months the total number of ships inspected at the five ports of Connah's Quay, Rhyl, Mostyn, Saltney, Chester, and Hawarden Bridge was 554 (nine foreign and 545 English), carrying crews amounting to 2062 men.

Deeside.—In his annual report on the sanitary condition of the Deeside district, Mr. William Anderson, Aboyne, the Sanitary Inspector, states that during the year small extensions were made to the Aboyne and Torphins special drainage and water districts. These were rendered necessary by the erection of new houses, and with a view of providing for the requirements of others which were likely to be erected on feuing ground situated within the area of both special districts. These villages are growing rapidly, and the supply of houses during the summer and autumn months was, as a rule, not equal to the demand. A considerable number of drainage and water supplies outwith special districts had been dealt with during the year. In a number of cases new supplies had been provided, while old ones had been greatly improved by structural alterations. These works had all been executed with the view of preventing pollution or contamination, and also with the view of having a proper supply of wholesome water at or within a reasonable distance of every dwelling house. Slaughter-houses were, speaking generally, fairly well attended to, and no breach of the bye-laws had been made. The schools were also in a fair sanitary condition, but the privies and urinals in connection with some of them were of a very primitive description and far behind the requirements of modern sanitation. Factories and workshops were in a fair sanitary condition; ventilation, lime-washing, and general cleanliness were well attended to. Alterations and improvements were made on four which were complained about. There were seven registered dairies in the district, and the lime-washing and general cleanliness were fairly well attended to, and also the health of the cows, which was a very important matter, as it was impossible for an unhealthy cow to produce healthy milk, and on the quality of the food supplied to the cow the quality of the milk largely depended.

Edinburgh.—In the third annual report of the Sanitary and Markets Departments of the city of Edinburgh, Dr. Williamson states that the attention of the department had, as usual, been largely devoted to the introduction of sanitary appliances, so as to render the houses so treated free from those common recurring forms of nuisance which abound in all cases in which any laxity was allowed to exist. In no fewer than 35 instances there was found an entire absence of water-closet accommodation for the occupants of inhabited dwellings, which deficiencies were at once rectified. In nearly 350 cases the existing apparatus was found to be so defective as to give rise to complaint and to become an element of danger. In nearly 200 instances insanitary apartments had been treated, with highly satisfactory results so far as ventilation was concerned. During the year 2000 complaints as to the non-sweeping and washing of common stairs had been dealt with, which had taxed the energy of the staff to the fullest extent. The duty which devolved upon tenants of keeping their houses in a cleanly condition had been strictly enforced, and in nearly 1600 instances had it been necessary to ensure that such work was satisfactorily carried out. The question of overcrowding continued to occupy a large share of constant work and supervision, and during the year 350 cases had been dealt with. In 219 of these, it was satisfactory to report, successful efforts had been made, while 130 known cases of overcrowding were at present occupying the attention of the department. Under the powers conferred by the Public Health (Scotland) Act, it had been necessary to take action in regard to certain businesses and trades of an offensive nature. The burden of having open spaces asphalted or cemented should be laid upon the proprietors. In such a condition these would be more suitable as playgrounds, and would not form such harbours for decomposing refuse as the majority of them do in their present condition. Throughout the city there were at least 335 open spaces which required constant supervision. The number of proprietors responsible for such varied from seven to twenty, and the number of tenants whose houses overlooked such spaces amounted in some instances to 100. Dr. Williamson submits that such facts should emphasise the desirability of an almost daily cleansing, and should further emphasise the great difficulty in having this accomplished in which so many proprietors and tenants are involved.

Gosport.—The annual report of the Gosport Medical Officer of Health has just been issued. Dr. Hunter states that there has been a considerable diminution in the death-rate as compared with 1899, though the number exceeds somewhat the average of the preceding five years. There have been 823 births during the year, of which 426 were males and 397 females. The number of deaths recorded was 606 for the whole district, or 50 less than last year. The death-rate for the whole district is 20·89 per thousand, whilst for the district proper, that is excluding the naval and military population, it is 19·28 per thousand. Infantile mortality is, says Dr. Hunter, much higher than it ought to be, and were ordinary precautions taken by those having the care of infants a great saving of life would necessarily result. Of a total of 606 children under the age of one year 135 died, the mortality rate being 164·03 per thousand births registered. This, however, is a slightly better record than in 1899, when the percentage was 183·7. Dr. Hunter requests that the earnest consideration of the Sanitary Authority should be given to the matter. The number of cases of infectious diseases notified was 261. Scarlet fever was much less prevalent than in 1899, when 251 cases were notified, as compared with 77 in 1800. Enteric fever, however, rose considerably above the average, there being 148 notifications as against 125. Diphtheria and erysipelas both showed diminution. The number of deaths from notifiable diseases numbered 39, as against 48, the mortality rate being 1·38 per thousand.

Lichfield.—Dr. James Clark has issued his thirteenth annual report as Medical Officer of Health for the city. He records that last year the birth-rate was 27·5 as against 28·9 for the kingdom, and that the death-rate was 21·6 as against 18·3 for the whole country. The

death-rate was higher than any other year since 1892, and 3·3 higher than the average of England and Wales. Zymotic diseases caused a very unusual number of deaths, comprising two from measles, 11 from whooping-cough, one from diphtheria, one from typhoid fever, and three from diarrhœa; total 18. This gave a rate of 2·3 per thousand, and was the highest recorded within his experience. In all 28 cases of infectious disease were reported, two of diphtheria, three of typhoid fever, 14 of scarlet fever, and nine of erysipelas, and for the first time since its establishment deaths had taken place in the isolation hospital. Up to the end of 1899 there had been 211 patients admitted from the urban and rural districts to the hospital without any deaths. During 1900, 34 more patients had been admitted, and two from the rural district had died. As bearing upon the sanitary condition of the city, Mr. W. Chovil, Inspector of Nuisances, reports:—"I have made an inspection of the city, and repeated my inspection very frequently in those parts of the city occupied by the poor. Much has been done to improve the tenements, but the structural defects continue, wihch is a source of danger to the health of the tenants. The want of ventilation and personal cleanliness, with proper facilities for light, is absent. I have been successful in effecting improvements in some of the cottages. Overcrowding continues a danger to the health of the people. The lack of suitable cottage accommodation is very much felt by the poor. I have frequently moved them from one tenement, and after a few days found them in another part of the city, living in an overcrowded state." Summing up his observations, Dr. Clark says:—"Although there has been some advance made in the removal of insanitary conditions during the year ended, I would supplement your Inspector's report by again urging upon you the great necessity that exists of a more regular system for the removal, or the more effective dealing with house and ash-pit refuse. Water-carriage being the best and most suitable system of disposal, old and foul privies should be abolished and water-closets of modern construction substituted, and the other sanitary and structural defects mentioned should be forcibly urged upon the attention of property owners with a view to their more prompt correction. These matters have been brought under your notice in former reports, and I again press them on your consideration."

Smethwick.—In his annual report for the borough of Smethwick, the Medical Officer of Health (Mr. W. F. Marsh Jackson) writes:—The general zymotic and infantile death-rates compare most favourably with those of previous years. The marriage-rate is, I am glad to note, higher than it has been for the last two years, but there is a falling off in the birth-rate. In 1892 and 1894 a similar falling off occurred. These variations in the birth-rate are probably due to accidental causes inherent to a working class population, which is more or less migratory. It is a fact, and as such it must be accepted. I may, however, say that the marriage-rate was lower than usual during the two years preceding 1900. Still, although this falling off of the birth-rate has occurred, the rate compares favourably with that of all England. The population has undergone a further increase. I assumed at the beginning of the year under notice that on the 30th June it would be 65,700. Supposing this conclusion to be correct, an increase of population over 1899 of 4200 is shown. The number of marriages that have taken place during the year is 415, and the marriage-rate for this period is 14·9 per 1000 persons living per annum. The number of births registered during the year was 1859—986 males, 873 females, exceeding the number registered in 1899 by 3 only. The birth-rate for the year under notice is 33·3 per 1000 persons living per annum, against 36·03 per 1000 in 1899. The deaths registered number 872, against 780 in 1899, comprising 454 males and 418 females. The death-rate for the year is 15·6 per 1000 persons living per annum, against 15·1 per 1000 in 1899.

St. Ives.—Dr. Nicholls, in his report for 1900 to St. Ives Town Council, stated that there were 193 births (males 51, females 64). The birth-rate per 1000 was 31·67, against 34·62 in 1899, and the death-rate 18·87, against 15·75 in 1899. The deaths included 36 under one year, 22 over 65 years, 12 over 80, and 1 over 90. Four of the deaths were visitors, seven deaths were from zymotic diseases, including four diphtheria and two diarrhœa; six (five females and a male) were from cancer; eight from phthisis, and three from influenza. Deaths from respiratory diseases had been more numerous, 10 being infants. There were 21 deaths at all ages. The infant mortality was at the rate of 186 deaths to 1000 births—a high rate, but chiefly increased by deaths from bronchitis in February and April. Many of these infants suffered from malnutrition and bad feeding. No epidemic sickness occurred. During the year 49 cases of infectious diseases were notified, a rate of 8·04 per 1000. A great improvement was manifest in the lower portion of the town, resulting from the increased facilities for refuse collecting, by which twice as much work is done. Thirty-four new buildings had been certified fit for occupation. The water supply was good, and fairly met the extending requirements of the town. In his general remarks the Medical Officer says the year has not on the whole been unfavourable. The birth-rate was a very good average, but none too good considering the leakage through infant mortality. The increase in the respiratory death-rate was, he could not help thinking, in many cases due to, or in part caused by, influenza, although the evidence may not have been sufficient to certify this as the cause of death.

SCHOOL SLATES AND DIPHTHERIA.

The suggestion that the indiscriminate interchange of school slates among school children may result in the spread of diphtheria has been made, and no doubt the danger is a real one. The slates are all wetted and washed in the same bucket, and if they should get dry during the school session, of course the spitting comes in again. Her Majesty's Inspectors condemn the practice of children spitting on their slates and wiping them with their caps. Still, the custom lives. To reduce this danger the following suggestion has been made. Every child on its entry into the school should be supplied with a suitable slate, and its name marked on it on both sides. The child would occupy the same place in the class and always have the same slate; or, if removed to some other part of the class, carry its slate with it. Slates falling out of use from children leaving, &c., might be washed in some suitable disinfectant before being re-issued.

It is questionable, however, whether any system of reserving slates and pencils to particular scholars or of repeated and efficient disinfection is practicable. Pencil and paper have taken the place of the slate in some schools, and this innovation has everything to recommend it. One would like to see it adopted in the London Board Schools.

Mr. Pandeli Ralli has given £1000 for the erection of a new ward to the Cranleigh Cottage Hospital in memory of his sister; and towards the erection of a second additional ward Lord Alverstone, Lord Ashcombe, Mr. Healey, and Mr. Waller have given £100 each, and Mrs. Barnard Hanney and Miss Summer £50 each.

THE SEVEN-PLACE DECIMAL.

In the course of a review of Col. Moore's "New Tables," a writer in last week's *Engineer* "lets himself go" on the matter of decimals. As a clever piece of writing it is worthy of a high place in the ranks of journalism. How far its exquisite satire is applicable to the denizens of the office of the municipal engineer, we leave our readers to judge for themselves. The writer says:—

The devotion of the professional part of the human engineering race to formula and long rows of figures is a profoundly mysterious and pathetic psychological phenomenon. The longer one ponders it, the more deeply is one convinced that there are certain fundamental ingredients in human nature that remain unchanged throughout the æons. One of these is the imperative need of the human mind to worship what it does not understand, and what it has no use for. For many a long century stocks and stones satisfied this mental necessity in the elementary form which it took in the babyhood of mankind. The stocks and stones were hewn and chipped into very angular and ragged shapes, and were worshipped with more and more blind and abject reverence the uglier and bonier they grew. They grew very ugly and very bony indeed, and men who mingled piety with a far-sighted and calculating prudence found it profitable to imitate them in personal angularity by reducing their bodily frames to emaciated skeletons. These men justified and supported this bony existence by help of astrological and other runic complex calculations which pretended to wrest secrets from the heart of Nature, but which were based upon not a shadow of a trace of a relation with the true living nerve and muscle of Nature's physiology. When at last they were found out, men could not worship them any longer, and had to search for more modern stocks and stones. China led the way in giving up the emaciation business, for which it had gone in heavily in its earlier history, but to this day it maintains the runic astrology as a strong political and social force. European nations in the past century found it necessary to invent new forms of meaningless and therefore mysterious numbered diagrams. The latest and most improved, up-to-date, and go-ahead fetish is the most subtle and most powerful of all the generations of all the fetishes. He is the Algebraic Formula and the Seven-Place Decimal. Everybody has implicit faith in the Algebraic Formula, because nobody understands him. Not being able to trip him, or to cut him up, or to tear him in pieces, they stand in fear and awesome trembling before him, and let him have his way. He rules in all the designing offices without question or hindrance, and poor Nature, asking for only a little attention and consideration, slinks away unheeded. And when he blossoms out and matures in the fruit of Seven-Place Decimals, men bow down in reverence before him and subscribe share capital, and ask only for a moderate percentage of their capital to be repaid to them in dividends. Most men are modest, and take care to leave him alone.

It is touching to observe the pious attitude of the professional engineer in his behaviour towards the Seven-Place Decimal. The first rite to be performed is, of course, to pay his guinea for his fifteen millions of printed figures which are to help him to tell the Public Works Committee whether the new sewer is to be 3ft. or 3½ft. in diameter. The payment of the guinea produces a glow of holy satisfaction and content. Then, if there be no pressing call at the telephone, he turns over the pages of the tables in awe-stricken dreamy admiration of the endless maze of S.P.D.'s rising tier upon tier in giddy columns *de profundis ad astra*, and stretching left and right from $-\infty$ to $+\infty$. Somehow they always seem to average in O, but this is only the effect of the daze upon the eyesight. The third rite to be performed is quiet contemplation of the shelves and pious consideration of in which place they —it, he, the fetish, the S.P.D.—would look best. The place is chosen, and the Tables are laid up in it. They lie there. They are taken down once every two years, to see that the S.P.D.—*Spiritus Pontificus Divinus*—is still there all right in his pristine glory and magnificence, and has not shrivelled into any semblance of common sense; also in order to wipe the dust off. From his quiet resting place upon the shelves, the Spirit is breathed throughout the office, and pervades the minds of engineers, without noise or effort, with potent inactivity. It is enough that he is there; he penetrates without pushing; he dominates without energy or the possibility of a germ of energy arising within him.

CHINESE PREJUDICE IN SANITARY MATTERS.

By Arthur Stanley, M.D., &c., Health Office, Shanghai.

In China considerable breadth of view and treatment is necesssary in hygienic measures. With an unsympathetic people like the Chinese, sweeping sanitary measures are difficult of operation, and though hygienic conversion is hard, dragooning is still less effective, and any attempt to hustle the East is poorly rewarded. The process of social evolution can perhaps be studied on broader lines in China than anywhere on account of its particularly massive and concrete historical records, and the lesson taught appears to be, that in many respects the methods of some centuries of practical experience are frequently confirmed as good by modern science. And it is by following out these methods in a spirit of scientific sympathy, tempered by an accurate appreciation of Asiatic environment, that the best results may be obtained. Although in sanitary matters action is sometimes taken *ultra vires*, it is essential the principle be maintained that in relation to public health the power of the Municipal Council is supreme. In dealing with Asiatics a little wholesome despotism is good, and in matters of life and death it is the duty of the Government to govern.

In its bearing on the attitude of the Chinese to modern public health measures, it may be noted that the prejudices of the Chinese against Western medicine are still strong. The Chinese are a people with a supporting belief in all kinds of drug charms and spells, and their medical methods are strictly empirical and mostly founded on the fancies of the alchemistical religion of Tao. The Chinese drugshops contain an immense number of drugs and preparations, are the most elaborately ornamental of all shops, and the Chinaman spends a large part of his income on medicines. It is not surprising, therefore, that public health measures, which are founded on organised common sense, and from which the personal factor of the relation between doctor and patient, with all its fallacies, is eliminated, do not appeal acutely to the Chinaman. He is attracted only by the merest scum of so-called Western civilisation furnished by well-advertised "patent medicines" and itinerant quacks. As in diseases the least curable there are the greater number of drugs recommended as cures, so it is with the Chinese, who, though ignorant of the real cause of disease, have a proportionately great desire for a multitude of drugs—the Chinese pharmacopœia is the largest in the world.

The Stockton Urban District Council has authorised the Medical Officer of Health to attend the annual Congress of the Institute of Public Health to be held at Bournemouth from the 25th to 30th July.

SANITARY INSPECTORS' EXAMINATION BOARD.

An examination for Sanitary Inspectors under the Public Health (London) Act, 1891, was held in May, 1901. The following is a list of the candidates who passed in the above examination, with the names of the Institutions at which the candidates received instruction :—

Name of candidate.	Name of Institution.
Miss J. Agnew	Sanitary Institute.
Miss E. I. Beeston	Sanitary Institute.
Miss A. E. T. Biggs	National Health Society.
Mr. J. L. Clark	Liverpool School of Hygiene.
Mr. T. W. Dee	King's College.
Mrs. T. Fisher	National Health Society.
Miss M. F. Hoe	Sanitary Institute.
Miss Anne Hutchinson	National Health Society.
Mr. E. J. Manders	University College, Cardiff.
Miss E. C. Martin	King's College.
Miss F. Potter	National Health Society.
Mr. T. Robinson	Liverpool School of Hygiene.
Miss M. Stampa	National Health Society.
Mr. S. W. Wingfield	King's College.

SHOULD PULMONARY TUBERCULOSIS BE NOTIFIED? *

By Dr. W. C. Chapman, Member State Board of Health, Toledo.

The subject of this paper, "Should Pulmonary Tuberculosis be Notified?" whilst more particularly one to be discussed by Health Authorities and physicians, appeals so closely to the sentimentality of the people, it is well to include them as interested hearers when considering the desirability of adopting measures to carry out such plans.

Before speaking specifically of "tuberculosis," it may be asked, Why should any disease be reported to the health officials? Is there sufficient benefit derived from the knowledge that infectious disease exists in a neighbourhood to repay for time and money spent in obtaining such information? And what can be rightly expected as a result of attempts made to prevent the spread of such disease by the boards of health?

Experience has shown that certain diseases are highly contagious, that they are easily communicable from one person to another, and that the only way whereby the spreading of infection can be overcome is by the enforcement of strict rules of isolation. If it were possible for attending physicians to see to the details of this work, and to institute sanitary measures, which include environment, then the health officer would become an almost useless personage. The diagnosis of the case has been made by the attendant, and rarely does the health department find occasion to reverse such diagnosis. Unless difference of opinion arises among local physicians, the occasion scarcely ever occurs in which such department should act, other than as an executive body charged with the enforcement of law. As an expert because of great experience, the health officer may be called to decide as to the disease under treatment, but then only in the presence of the attending physician, and most frequently at his request. All isolation regulations should be controlled by the Health Authorities, and they should have, as they do in this State, full power to enforce them. Tracing the local cause for disease is one of the duties of the sanitary officer, and many an epidemic has been stayed by scientific, and therefore laborious investigation. The discovery of the polluted well, or stream of water, amply repays for all expenditure. It is therefore to be expected that well-directed, systematic effort, will minimise the dangers from contagious or infectious diseases.

* A paper read at the eleventh annual meeting of the Ohio State Board of Health, 1901.

Having demonstrated that diseases classed as contagious may be combated by modern methods, and communities freed from epidemic influence, there is no objection upon the part of anyone to the enforcement of restrictive measures. It is only when the contagious nature of a disease is questioned that opposition comes. The public is sure that scarlet fever, measles, diphtheria, and like diseases, are contagious, and therefore willingly submit to reasonable control; but taking the one under consideration, consumption, its contagiousness is not so apparent. When doctors disagree, why should not the laity?

The question is asked, Is consumption a communicable disease? Does it attack the well-nourished, and therefore healthy? Otherwise, can the specific tubercular germ be implanted in a normal being, then developing and destroying until death ends all? It requires years of teaching to overthrow early belief, and only a few years have passed since all were taught that consumption was a hereditary curse handed down from ancestry. Those who could look backward upon a family history without taint would remain free from the disease. Insurance companies confirmed this belief, as they do to-day. The family history of consumption prevents the issuance of a policy. Believing, as most investigators do, that the tubercular germ may be conveyed through the air and implanted in proper soil in any lung, it is not possible to consider the disease other than a contagious one. Differing from others, in that it is one which develops slowly, and cannot be communicated to a healthy person, there must be primarily a lesion before implantation of the specific germ is possible. A lengthy, close relationship, as sleeping in the same bed, or occupying common apartments, nursing the afflicted one, or otherwise remaining in close contact, may after a time convey the disease, but never does it pass through a definite prodromic stage, and in an abrupt development quickly manifest its presence.

In attempting to arrive at a satisfactory conclusion in regard to the matter of reporting cases of comsumption, the question comes, Why should they be reported? Being a chronic disease, easily recognised by the attending physician, and so far only amenable to hygienic and restorative treatment, without specific medication, what benefit can be obtained by the patient from the intervention of the health officials? The answer is, nothing. What may be expected in the way of preventing friends and attendants from becoming infected with the disease? Here the answer is the same, almost nothing. The few rules to be followed in the care of sputa and other excretions are so simple, that they scarcely need mentioning. There can be but one benefit that can accrue to anyone, and that is the obtaining of statistics, so that comparative tables may be prepared and the ratio of recoveries to death may be obtained. It is known that tuberculous patients have frequently recovered. The proportion is not tabulated, but could be determined with considerable accuracy if all cases were known to the Authorities. Boards of health may investigate residential surroundings, and advise as to sanitary regulations of the home, but this action would be resented by the physician, and might prevent the intended good. There must also be a great change in the sentiment of the people before they will agree to be separated from the loved ones dying of lingering disease. They will consent to the removal from home by the advice of the family physician, but are unwilling to obey the unsolicited advice of an officer. There seems to be a rising and almost insurmountable obstacle to the enforcement of rules in regard to the supervision of consumptive cases by the officer of health, and that is the prejudice of the physicians. A very conservative body of educated men see no adequate reason for troubling themselves to make reports of their tuberculosis cases. If any benefit could be proven, acquiescence might be prompt. If such a positive preventive procedure as vaccination against

small-pox is ignored, or strongly objected to, by quite a large percentage of physicians and people, how can it be expected that they will permit of the quarantining of consumptives? Care must be taken that health boards and health officials do not undertake to rapidly and radically assume authority. There seems to be rising all over the world a sentiment that certain men are endeavouring to force opinions which have never been proven, by close investigation, to be correct. A notable example of this feeling is shown by a translated article in the *Lancet and Clinic*, December 29th, and a quotation may be considered to the point. The article is from the pen of Dr. A. Lutaud, editor of the *Journal of Medicine*, of Paris:—"The mania to legislate on the matters of medicine and hygiene, derived from England and Germany, has now developed in France. Not only are laws made more or less oppressive to the liberty of the people, but even against the rights of the physician himself. That which startles is the fact that such legislation is established at the instance of individuals belonging to our own medical corporation. It is certainly not the general practitioner, those who gain a living honourably and by hard labour in the exercise of the medical profession, who have asked for the passage of such enactments against personal liberty and added restriction to the art of healing; the latter know full well the dangers of contagion."

Much follows this quotation, most of it being an attack upon modern serum medication, it is an exaggerated statement of well known procedures that have often benefited mankind. This article is mentioned merely because it shows that opposition will come in the house of supposed friends; but it also shows that the profession and the laity are not willing to advance rapidly in adopting new procedures.

A warning note is given by our friend, the editor of the same publication, December 15th. "It is recognised," says he, "that the police power of the State and municipality is, to all intents and purposes, almost unlimited. It is this absolute power of the State over the citizen that makes it possible for the boards of health and health officers to enact arbitrary regulations, which are an offence that is quite intolerable."

In concluding this paper, in view of opposition by the profession and the laity, and because of only slight benefits to be derived by the public and the profession, it seems advisable that pulmonary tuberculosis should not be notified, as other contagious diseases, to the Health Authorities.

PUBLIC HEALTH IN THE DAYS OF MOSES.

In the domain of public hygiene we find most wonderful evidence of the great genius of the greatest legislator of all times and his prophetic anticipation of many of the discoveries of modern science of medicine and hygiene. The preservation of forest, disposal of excreta, vital statistics, notification of infectious diseases, sanitary inspection, isolation, diagnostication of contagious diseases, quarantine, fumigation and disinfection, all these terms seem to read like titles of chapters in a modern text book on hygiene, but are nevertheless mentioned in the Pentateuch and were made by Moses part of his system of sanitation for his chosen people.

In Book 5, ch. xx., vs. 19 and 20, we read: "When thou shalt besiege a city, &c., thou shalt not destroy the trees thereof, for thou mayst eat of them, and thou shalt not cut them down, for the tree of the field is man's life"; here we see that Moses has recognised the value of vegetable life and the preservation of trees in their relation to the sanitary environment of the people. In the same book, ch. xxiii., vs. 12 and 13, we find a very wise rule for the disposal of excreta in camps. Every camp had to have a special place outside its boundary where the people were compelled to go to, and, especially for this purpose, made paddles on their weapons to dig and cover with earth their excrementitious matter.

In Book 4, ch. xvi., we read: "Now they that died of the plague were 14,700," it is evident, therefore, that Moses had some system of vital statistics, else the number of those who died would not have been known.

There are many speculations and commentaries on what was meant by "Zoraath" and leprosy mentioned so many times in the Bible, but it is conceded by all who studied the matter that those diseases mentioned by Moses were epidemic, contagious, and infectious, and the laws in regard to them, with a view to prevent their spread and keep them within bound, are certainly remarkable in their thoroughness as well as anticipation of discoveries of modern science. Chapter xiii. of Leviticus is a very definite and detailed section of infectious diseases. "When a man shall have in the skin of his flesh a rising, a scab, or bright spot, &c., then he shall be brought unto the priest," here we, as well as in the latter expression, "he shall come and tell the priest," find the rudiments of compulsory notification of contagious diseases. And the priest shall "look and behold." Here the duty of diagnostician is imposed upon the priest, who is the spiritual as well as health officer. Should, however, the priest not be able to determine the nature of the disease, or even if he should be in doubt, then "the priest shall shut him up for seven days." Here we find the principle of temporary isolation. When after isolation the disease is finally diagnosticated as an infectious one, then the one infected was pronounced unclean, and "all days wherein the plague shall be in him he shall be defiled, he is unclean, he shall dwell alone, without the camp shall his habitation be." After recovery and quarantine of the infected, we find a whole procedure for disinfection for the patient and his clothes as well. "And he that is to be cleansed shall wash his clothes, shave off all his hair, and he shall wash his clothes, also his flesh, in water, and he shall be clean," not, however, before a disinfection with a mixture of "cedar wood, hyssop and scarlet," a phenol group of that period.

The system of sanitation of Moses embraces not only man and his clothing, but also the house. In the same chapter quoted we find quite an interesting section on house inspection, &c.: "And he that owneth the house shall come and tell the priest" (it seems then that the duty of complaining and notifying was imposed upon the owner of the house), saying: "it seemeth to me there is, as it were, a plague in the house." Then the priest shall go and see the house (not, however, before the house is emptied by its inhabitants), and behold, "if the plague be spread on the walls of the house, then the priest shall cause the house to be scraped within round about, and they shall pour out the dust that they scrape off without the city into an unclean place." But, if after this procedure, the house is still unclean, then the priest "shall break down the house, the stones thereof, &c." Quite a radical measure, the extent of which is limited even in our most modern sanitary legislation.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

The following meetings will be held at the new offices 19, Bloomsbury-square, W.C., on Wednesday, June 12th, 1901.

General Purposes and Finance Committee at 4.0 p.m.
Half-yearly General Meeting at 7.0 p.m.

It is reported that Mr. J. P. Morgan, the American millionaire, is paying for the cost of the installation of the electric light in St. Paul's Cathedral.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

MAY 30, 1901.

SANITARY SCIENCE AND LONGEVITY.

THE writer of a recent article in the *Scotsman* draws some instructive comparisons from an analysis of the figures in the report of the Registrar-General for Scotland for 1900, as illustrative of the changes in the length of life during the last seventeen years. The figures dealt with by the writer are those for the eight principal towns of Scotland, which may probably be taken as exhibiting in the most marked degree the operation on human life of the advance of modern sanitation. In the country, with its greater slowness to receive and apply sanitary ideas, the change can hardly be expected to be so clearly marked. The years brought under notice for purposes of comparison are 1883, 1898, and 1900. From an examination of the figures for these years, the proportion per cent. of the deaths at each age—from birth to five, from five to twenty, from twenty to sixty, and over sixty—to the total number of deaths, is explicitly brought out as follows :—

In 1883, up to the age of five the death-rate was 41·1; in 1898, 39·7; and in 1900, 36·2. From the age of five to twenty the rate was for the three years respectively 10·4, 7·3, and 7·1; from twenty to sixty, 30·1, 32·0, and 33·5; over sixty, 18·4, 21·0, and 23·2; the total death-rate per cent. for the three years being 2·0240, 1·8447, and 1·9070.

The most striking feature of these statistics is that in the early ages of life, and more particularly in the case of young children, there has been a progressive decrease in the ratio of mortality to the total mortality; or, in other words, the chance of life for the young has been steadily on the increase. That this is due to greater care for the young, owing to a more widespread attention to observance of the laws of health, there can be little doubt, and the statistical evidence of the fact is most satisfactory. On the other hand, when we pass to the ages over twenty, we find an increase in the percentages, which, however, is but the natural consequence of the preservation during early years of many of those lives which would at a former period have succumbed in the struggle for existence. To a certain extent, therefore, the advance of sanitary science would seem to bring about a revolution in the Darwinian law of "the survival of the fittest." Reduced to percentages, the difference between 1883 and 1900 works out as follows :—Between birth and five years of age, the increased immunity from fatal disease is equal to 11·9 per cent.; between five and twenty, the increase is even larger, viz., 31·7 per cent.; while between twenty and sixty, the augmentation in the mortality ratio to the total deaths is represented by 11·2 per cent.; and over sixty by 26·09 per cent. From another set of comparisons of the years in question, as illustrating the mean age of death, we have the following results :—In 1883 the mean age was 27·2; in 1898, 29·4; and in 1900, 31·4; representing a mean increase in life between 1883 and 1900 of 4·2 years, or about 15 per cent. Taking, again, the mean age of those dying above five years of age, the figures are 44·5 for 1883, 47·1 for 1898, and 47·7 for 1900; and for deaths occurring above twenty, the mean ages are 51·4, 51·8, and 52·2 respectively. All along the line, therefore, a progressive increase in longevity is recorded, which must be placed to the credit of sanitary science. The writer from whose analysis the foregoing abstract of figures has been taken pursues his investigation with great minute-

ness of detail with regard to the statistics for each individual town, showing that in point of longevity Perth occupies the place of honour among the eight chief Scotch towns, and Glasgow takes the bottom place in the list. In summarising his results, he remarks that this increase in the duration of human life is attended with some drawbacks; for "an increased proportion of less robust lives are included in those entering upon adult life, while more deaths from more chronic causes play the part formerly taken by the acute and brief diseases of childhood and youth."

The Treatment of Consumption in Edinburgh.

It will be in the recollection of our readers that a very elaborate report on the treatment of consumption was last year submitted to the Town Council of Edinburgh by the Public Health Committee. One of the most important recommendations in the report, following on a suggestion of Sir Henry Littlejohn's, was that provision should be made for the reception of a hundred cases in the last stages of consumption, and the proposal was made that for this purpose a hundred beds might be fitted up in the Infectious Diseases Hospital, the buildings of which would be rendered available by the removal of the establishment to the new Fever Hospital at Colinton. The proposal was not acted on at the time, and the Public Health Committee are now again moving in the matter, and urging on the Town Council the desirableness of taking action at an early date. The portion of the report which explains the proposal, its feasibility and cost, and the estimated benefit to the city, is of great public interest. The cost, it is stated, "would not exceed £50 per bed, or an annual expenditure of £5000. The result would be the immediate abstraction of a hundred sources of dangerous infection. Unhappily, patients who have come to that stage have only a short expectation of life. In a similar institution under the municipality of Paris the experience is that the average life of such patients received into hospital is only three months. That would mean an admission of 400 patients in the course of a year. But even if only 200 patients were received in a year, this would imply a very large reduction of dangerous risk to the lieges." Turning to the financial aspect of the case, the Report proceeds to ask the question, "May the city look for an adequate return for such an addition to its annual burdens?" It may be respectfully answered that, upon the evidence of figures set forth in this Report, there is no expenditure of public money more likely to yield an ample and immediate return. It is not unreasonable to expect that in the way suggested within ten years the mortality from consumption in Edinburgh will be reduced by 200 per annum. But if only 100 lives were saved to the community, it may be claimed that the expenditure would be justified. Upon the experience of last year, the average age at which we lose our people through consumption being about thirty-three, it may be reckoned that each saved life may be taken as good for ten years of labour. There is good authority for taking the annual wage-earning power of each citizen at £35, and £35 capitalised at ten years' purchase would give £350 for each saved life. If the mortality were reduced by only 100 lives, the saving per annum would then be £35,000, which must be admitted to be ample return upon an annual expenditure of £5000. To this saving there should be added the further saving of sick bed expenses, and loss of wages of the victim. It is intended to bring the matter before the next meeting of the Town Council, as the subject is considered one of great importance, if not of urgency.

Burial Amenities in the Hebrides.

The innate conservatism in some matters of the people in the outlying portions of the Highlands makes it difficult to instil into their minds certain elementary ideas of sanitation. An instance of this has occurred in connection with a graveyard scandal in the island of Harris, which is receiving the attention of the Local Authorities. According to the report which has reached us, "the cemetery at Maraig has been allowed to get into a disgraceful state of overcrowding, its general condition being described as a mound of human remains. Of late years, coffin has been placed upon coffin until it was only possible to scrape together from 7in. to 15in. of earth for a covering, the average depth being 9in., while in one spot the coffins are laid side by side, and have only a slight covering of turf over them. The ground has been closed by Privy Council Order; but so tenaciously do the people cling to the old place, despite these disgusting conditions, that no fewer than four interments have been made in defiance of the Authorities." Such a state of things should be deemed disgraceful to any community, but the people of the Western Hebrides seem to be deficient in sensibility in such matters. They cling to the ways and customs of their forefathers, and are slow to appreciate or welcome the march of sanitary ideas. Is it any wonder in such circumstances that fever is ever rife in their midst?

A Place where Pigs are Raised.

In his report on the sanitary condition of the rural district comprised in the Spalding union, Dr. Fletcher gives the description of a farmyard he came across in the course of his inquiry. It was in combination with a slaughterhouse, which opened into a barn, and this in turn opened on to a large manure heap. "On one side of this," says Dr. Fletcher, "was a roughly-constructed pig-stye in a filthy state, and on the other side a swamp of blood-stained washings from the slaughterhouse, which is unprovided with proper drainage. Throughout the district pigs are looked upon as manufacturers of manure. Straw is placed in the run adjoining the stye, and, not only is this left to be trodden down by the pigs with their own urine and excrement, but soiled straw and manure is removed from stables and cowsheds, and is also thrown in. This

process is repeated time after time, and the level of the material rises in the run until it may become three or more feet higher than the ground level, and in wet weather the whole becomes trodden and churned into a decomposing mass of filth, in which the unfortunate pigs wade about, carrying the filth into their styes, and fouling them to such an extent that they have not a clean or dry place to lie on excepting when the interior is provided with fresh straw. Observing one run in front of a stye at Moulton in a very filthy state, I spoke to the owner, a farmer, about it. He seemed surprised, and said that he had cleaned it out only the week before, removing *three loads!* While on the premises some straw and cow-droppings from the adjoining cowsheds were thrown into the run, and some young pigs at once commenced routing amongst it and devouring the manure. The man expressed the view that the pigs got from it any nutriment left by the cow. This may be true, but the practice is disgusting at any time, and especially so when it is considered that the pigs are intended for human food. In this district the pigs practically spend their lives on manure heaps, and devour any filth thrown to them." This utter disregard of all ideas of decency and cleanliness is not confined to the piggeries. In some places, owing to want of cleanliness, want of drainage and insufficient room for the animals, they are in some cases unable to lie down without actually resting upon their own excretions, hence they become in a filthy condition, and their hind quarters, and in some instances even the udders, become fouled with filth. Dr. Fletcher does not hesitate to say that the chief reason for this neglect of sanitary law is largely due to the inadequate administrative staff of the union, and urges as the first step in the path of reform the appointment of a full-time Medical Officer of Health. Spalding has often been urged to do this, and thus bring itself into line with all the other unions of Lincolnshire. It has hitherto neglected to do so, but the Local Government Board has given it to the 24th of June to amend its ways. If it is not done by that date the Board will have something else to say upon the subject.

Local Government in Ireland.

The twenty-eighth annual report of the Local Government Board of Ireland has recently been issued. In many points it possesses exceptional interest, as it deals with the period of transition from the old method of local administration in Ireland, to the new one inaugurated by the Act which established County and District Councils almost similar to those existing in England. Notice is taken of the fact that more than 4000 elections took place upon the same day without a hitch, a point which should not be overlooked by those who advocate that parliamentary elections should all be held on one day. At the outset of their existence the Councils met with many difficulties, notably the refusal of the banks to give financial aid except under guarantees from the Central Board. In the end it is thought this action may really be beneficial, as already the County Councils have had the wisdom to secure good credit balances. Much time has been spent in adjusting the relationships between officers and Councils, and, although one or two special cases have arisen, on the whole matters have now been adjusted, and it would appear that the administrative machinery is in fair working order. The predictions of those who said that the Irish would prove themselves incapable of carrying out the new system are being belied, for the County and District Councils have, with few exceptions, properly discharged the statutory duties devolving upon them, and the Board is confident that ere the first Councils have run their course, everything will be quite in order. In dealing with the public health statistics the Board reports a decrease of 2039 reported cases of fever, and that only 19 cases of small-pox were treated by dispensary Medical Officers during the year. Reference is also made to sewerage works and water supply in rural districts, closing of burial grounds, the enforcement of the Food and Drugs Act, and loans under the Public Health Act (amounting to £4,476,712). Under the Housing of the Working Classes Acts loans have been sanctioned to the amount of £375,164, while for providing labourers' dwellings loans were sanctioned to the amount of £29,816, and grants of £3005 made to boroughs and £36,994 to counties. Out of 16,303 houses authorised, 14,385 have been provided, of which 14,281 are actually let, and 303 others are at present in progress or contracted for. Further improvement schemes have been or are about to be submitted, proposing to provide 8177 new cottages, 2725 additional half-acre allotments to cottages already sanctioned, 277 allotments to existing houses, and 80 acres of land to be parcelled out in allotments to be let to labourers living in villages or towns. The estimated cost of these schemes is about £1,358,135.

Sources of Enteric Fever.

The reference in Sir Henry Colville's book to the causes of enteric fever in South Africa, has given rise to considerable comment in the daily Press, and has called forth one or two interesting letters from private individuals. One of these, giving the personal experience of the writer on the Australian goldfields, is worthy of note, not perhaps for any striking originality, but because of the experience it records. Writing to the *Morning Post*, "Prospector" says: "I would point out that the experience of medical men on the West Australian goldfields, where typhoid and enteric were in the earlier days terribly common, points to bad water as the chief source of infection. Fevers have practically disappeared from Kalgoorlie and Coolgardie now that pure condensed water is obtainable, and Cue is quite a healthy town, though six years ago the normal death-rate was 1 per cent. per diem among the pioneers—to all intents and purposes picked men physically, in the prime of life. In those days drinking water came from surface

pools, and was very dangerous stuff to tackle, but subsequently numerous wells were sunk and good water is abundant. The water of Mount Magnet, sixty miles from Cue, is excellent, and cases of typhoid are not more frequent than in the coastal towns. I have heard the 'dust theory' advanced, but do not think there is much in it. Disturbing the vegetable deposits is productive of a mild kind of low fever, accompanied by headache, but the effect is, generally speaking, only temporary, and must not be confounded with true typhoid." This fully confirms the views stated to us a short time ago by one who had done every colony now gathered into the great Australian Commonwealth, and, really, if we only trace back the history of typhoid epidemics at home, a like result is obtained.

The Changes of a Year.

In his annual report to the Surrey County Council, Dr. Seaton draws attention to the remarkable number of changes which took place in 1900 in the Medical Officers of urban and rural districts of Surrey. Of the thirty-four Medical Officers in the county, sixteen had been changed in the period under review. Dr. Jacob, who has served his Authorities in a manner that has won the admiration of the Local Government Board, decided to relinquish eleven out of the thirteen districts for which he was responsible. His retirement was the subject of universal regret to his colleagues. Reference is also made to the changes in the Guildford rural and Woking districts by the death of Dr. Wellington Lake; at Camberley by the resignation of Dr. Walcot; at Richmond by the death of Dr. Rowland, and at Barnes by the resignation of Dr. Adams. Taking into consideration the two joint Hospital Boards of Mogden (Richmond and Isleworth) and Stoke (Guildford, Godalming, and Woking) there were in all eighteen appointments to be thought of and dealt with, either separately or in combination. In regard to the new appointments, Dr. Seaton expressed the opinion that there were good prospects of having a staff efficient from the standpoint of modern requirements. He anticipated that one important outcome of the changes would be more official attention, in which he expected in due course to share, to the housing question. The sources of milk supply might also well be more under supervision, and in some instances the work of the district Inspector would, no doubt, be closely followed up.

Nice as a Health Resort.

It is a moot point with many people as to whether some of the so-called "health resorts" on the Continent are really what they are represented to be. Take, for instance, the case of Nice, from which place Consul-General Sir J. Harris has recently reported on the trade and commerce for 1900. This, he points out, depends largely upon what "the season" is. But from what he says we do not see that there are any special reasons why people should flock to the town. It is said that during 1900 the public health was "fairly good," because only 36 cases of typhoid were registered by the Bureau d'Hygiène for the whole year. The deaths registered numbered 2311, or about 21 per 1000. This may be a satisfactory rate for France, but we do not deem it so in this country. There are manufacturing towns that can show a better return than this, and there is not a suburb round the metropolis but what would be greatly concerned if its death-rate approached within half a dozen points of such a figure, whilst the average for such a county as Surrey is only 13·7, with about a dozen urban districts where the figures are less than than 10 per 1000. In another part of his report Sir J. Harris states that "the tables and statistics of mortality published each month by the Bureau d'Hygiène appear to me to leave much information out of account which would be of interest. Thus, broncho-pneumonia seems accountable for 210 deaths during the year, and it would be desirable to know how many of these grafted themselves on a previous attack of influenza. There are, moreover, no less than 637 deaths to which no cause whatever is assigned." Of course this may have been put in to let the town down as lightly as possible. But it is quite clear that there is nothing in the vital statistics of Nice, and in fact of many other places in the Riviera to warrant their choice as health resorts in preference to many in our own country. Indeed, perhaps it would be more correct to say that the unhealthy pastimes—for both mind and body—of these places are the greatest attraction to a certain class of individuals.

THE EXTENSION OF CALCUTTA.

The extension of Calcutta southward, the removal of the insanitary bustis that once disfigured the finest residential portion of the town, and the erection of new and magnificent buildings have recently been proceeding with such extraordinary rapidity that we shall shortly be able to speak not only of Greater Calcutta but of New Calcutta. It is especially a matter of congratulation that the bustis, which clung, fungus-like, to the main streets, and gave Calcutta so bad a name among visitors and tourists, are coming down. At one time there was scarcely a street in the block between Park-street and Lower Circular-road which did not contain collections of these unsavoury huts. At the present moment nearly all these streets are clear. A large portion of the worst bustis, that which fronted on Theatre-road and Camac-street, is now being pulled down, and doubtless the whole of it will go as soon as the lease of the present tenant expires. Again, Bamun Busti, which gives its name to one of the most aristocratic wards in Calcutta, is on its last legs. The huts lying between Ballyganj, Circular-road, and Lansdowne-road, were pulled down recently, and the process of demolition is extending westward. These improvements are, however, not due to the municipality but to private enterprise. The very insanitary busti near the north entrance to the docks has been partly cleared away, we understand, by the Port Commissioners, and further south the Bengal-Nagpur Railway has taken up and cleared an enormous area, which was formerly packed with huts of the most primitive description, with no system of ventilation or drainage. The inhabitants of the reclaimed areas have gone down still further south where, though they are further from their work, hut rent is cheaper, and there is more room in which to live and breathe.—*Englishman.*

CORRESPONDENCE.

(*To the Editor of* The Sanitary Record.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

AUTOMATIC REGULATION OF BACTERIA BEDS.

Sir,—In the "Cross-Table Chat" in your issue of the 16th inst. there is a paragraph mentioning the various apparatus which has been got out for the automatic charging and discharging of bacterial beds. The writer is good enough to recognise our position as the first to bring out apparatus for the purpose; but later on in the paragraph he makes a remark which is calculated to do injustice (no doubt unintentional) to our own and possibly to some other systems. Speaking of an apparatus which has been recently introduced, he mentions that the inventor claims "that by its use there is no loss of head," the suggestion being that head is lost with the other types of apparatus mentioned. As those of your readers who have visited any of our town installations will be aware, our alternating gear works without loss of head, so that its employment does not increase even by an inch the fall which the filters would require if used without gear. This holds good with the shallowest filters in use.

We might add that the requirements which an alternating gear is called upon to meet are much more stringent now than they were when the original works at Exeter were laid down. It is generally considered that the beds should be filled quickly and kept full for a fixed period of time, and drained completely after each discharge. It is also held by many that the opening of the discharge valve should be gradual, so as to prevent the initial rush which would otherwise take place. Our gear is accordingly designed to meet these requirements, as well as that of the Local Government Board that the length of the cycle should be maintained at eight hours as a minimum.—Yours faithfully,

Cameron, Commin, and Martin.

7 and 8, Bedford-circus, Exeter,
May 25th, 1901.

CRIME IN LIVERPOOL, VIRTUE IN LONDON.

Sir,—I note that at the Liverpool Police-court a firm of butchers has been fined for selling as New Zealand lamb meat that had come from Australia, while another firm was also fined for selling River Plate mutton as New Zealand lamb. These are doubtless heinous irregularities, but they pale in comparison with those committed in many butchers' shops in London and the suburbs, namely, the offence of selling as English and Scottish meat the aforesaid Australian, New Zealand, and River Plate mutton, all to my taste equally bad. I am quite despairing of ever tasting either real English beef or mutton again.—Yours faithfully,

X. Y. Z.

FACTORY *v.* HOME-MADE CLOTHING.

Sir,—It is by no means an uncommon occurrence for doctors and sanitary officials to find very great difficulty in tracing the source of infection in cases of notifiable diseases. I wonder how often the link could be found in some one's new suit of clothes. I have often thought of the great risks that are run through the introduction of new clothes into the house which have been made by outworkers. A great prejudice exists in the minds of most men and women against factory-made clothes, yet they are undoubtedly made under better hygienic conditions than those purchased at the fashionable tailors'. In the case of the factory there is the great protection of the Factory Acts. In that of the outworker, no protection whatever. I have often noticed the untidy, dirty-looking young women taking the work into first-class tailors' shops, and only this week saw a girl of about seventeen taking clothes into a good-class City tailor, who was so dirty in appearance that it would have been a public benefit if she could have been taken away to a workhouse, and had her clothes burnt, and the order of the bath conferred upon her.

No doubt my experience is that of others, and I should like to see some steps taken to remedy this condition of things.—Yours faithfully,

J. Robinson.

London, S.W., May 28th.

DIRTY PUBLIC VEHICLES.

Sir,—Some time ago you called attention to the dirty condition of many of our public vehicles—especially emphasising the railway carriages on the Southern lines. I was travelling on one of these lines and saw a notice asking passengers not to put their "feet upon the seats"—some one had added "or you will dirty your boots;" and although the addition was humorous, it was absolutely true. Can nothing be done to compel the offenders to clean their carriages? If the dirty vehicles happened to be cattle trucks the companies could and would be fined, but I know of no means of compelling them to keep clean the carriages used by poor suffering humanity. Again I ask, can nothing be done?—Yours faithfully,

F. Johnson.

REVIEW.

The Economical Disposal of Towns' Refuse. By W. Francis Goodrich, A. I. Mech. E., with seventy-five illustrations. P. S. King and Son. Price 10s. 6d. net.

We have already many books on "refuse destructors and the disposal of town refuse," and this adds one more to the number. The author in his preface informs us that "previous works on the subject have been confined to the disposal of refuse in this country, which," he says, "has been a mistake," and he has introduced information as to American practice. Later on he informs us that there is nothing to compare with our modern British practice, so that after all the necessity for another volume is somewhat doubtful. The work follows very much on the lines of Maxwell's "Removal and Disposal of Town Refuse," and excepting the particulars relating to foreign practice there is really little that is new. Mr. Goodrich is an ardent advocate of refuse destructors, and holds that house refuse has a greater calorific value than is generally supposed, and instances the steam power obtained from burning refuse in Oldham, Rochdale, Darwen, and Warrington. Against this, however, must be set the fact, which is not touched on by the author, that these towns are adjacent to coalfields, where coal is cheap and house refuse contains an exceptional amount of cinders which is not found in districts away from coalfields. Nevertheless, destructors are becoming indispensable in nearly all urban districts, owing to the difficulty of other means of disposal of the refuse from such districts, and it is desirable that Local Authorities should have all the information possible before them before deciding upon the class of destructor to adopt, and whether it is profitable to attempt to utilise the power said to be available for purposes such as electric lighting, &c., and thus have what is termed a combined power plant or otherwise. The author has, however, it appears to us, a good practical knowledge of refuse destructors, and his book is deserving of careful perusal.

Public Works.

SEWERAGE.

DALKEITH has obtained a loan of £1200 for drainage work, and £250 for a disinfecting apparatus.

THE Clerk to the Blaby Guardians has been authorised to make application to the Public Works Loan Board for a further loan of £1411 for sewerage works at Kirby Muxloe.

THE Barrow Rural District Council has sealed a mortgage for £5500 for works of sewerage at Birstall, and has also ordered another mortgage to be sealed for £2145 for works of sewerage at Newton Linford.

THE Bristol Sanitary Committee has resolved to recommend the Council to carry out the construction of the Malago sewer, which formed part of the general sewerage scheme of 1900, at an estimated cost of £27,000.

A SPECIAL meeting of the Machynlleth Urban District Council was held last week to consider the sewerage disposal scheme. The further consideration of the matter was adjourned to the ordinary meeting, the clerk in the meantime to negotiate for suitable land for the works.

FOLLOWING upon the visit of a deputation representing the Royal Commission on Sewage Disposal, to the Beaumont Leys Farm, Leicester, the Borough Surveyor (Mr. E. G. Mawbey, C.E.), has just given evidence before the Commission upon the results of recent experiments in the bacteriological treatment of sewage on the Leicester sewage farm.

THE London County Council, has agreed on the recommendation of the Main Drainage Committee to repair the invert and side walls of the Islington branch of the London Bridge sewer for a length of about 3000ft. between Liverpool-road and Canonbury-road. The work is of such a nature as can only be carried out under a schedule of prices, as it is not known until the repairs are in progress how much of the brickwork will have to be replaced. The cost of the work is estimated at £1950. The Council has also decided that extensive repairs be made to the St. John-street sewer, Clerkenwell, for a length of about 1800ft. between Northampton-street and Albemarle-street. The work will be carried out under the jobbing schedule of prices, and the total cost is estimated at £1170.

A SECOND Local Government Board inquiry was held at Hungerford last week into proposed schemes for draining the town of Hungerford. Unfortunately the result will in all probability be the same. The former scheme was rejected by the Local Government Board on account of the unsuitability of the proposed site of the outfall works, and from the remarks of the Inspector it was evident he regarded the proposed site as being similarly at fault. Mr. Cuss, the engineer, received a lengthy cross-examination from Colonel Slack, the plans and figures being exhaustively dealt with. The scheme proposed to collect the sewage by gravitation to a place called Phelps' meadow, and then it was pumped into a septic tank, or rather a receiving tank. It would be pumped and treated by the bacterial system. The Inspector pointed out the Local Government Board did not sanction such treatment. Mr. Cuss said it was successfully at work at Sutton and other places. This site was the only one available to them without applying for compulsory powers to purchase land, but there were other sites which would be better. The population which would be dealt with under the present plans was estimated at 3000, and the dry-weather flow would be about 20 gals. a head. The water supply was from wells, but there was a scheme in hand for the establishment of a waterworks.

AT a recent meeting of the Hunslet Rural District Council a report was read with reference to the Middleton sewage disposal works, and Mr. Shaw was instructed to prepare plans and estimates for two new settling tanks, the work to be pushed forward as quickly as possible.

THE Sewerage Committee of Aberdeen Town Council met last week and proceeded to inspect the progress of the work at the great sewage and electric-cable culvert at Dee Village. By the aid of candle light the committee walked along the inside of the culvert as far as Marywell-street, and had ample opportunity of viewing the work.

LIEUT.-COLONEL SMITH held an inquiry at Eastbourne last week into the application of the Town Council for permission to borrow £2200 for a public library and baths at Seaside, £1200 for storm water drainage, £875 for the improvement of the Old Tollgate Bridge, and £593 for making up the road to the destructor. The proceedings were of a formal character, and no opposition was raised.

AT a meeting of the Birmingham, Tame, and Rea District Drainage Board, held at the Council House last week, on the recommendation of the Finance Committee, it was decided to borrow £82,000 from the United Kingdom and General Provident Institution at 3¾ per cent. interest for twenty years. The Works Committee recommended the tender of Messrs. Thomas Lowe and Sons, at £8375, for the construction of main carriers between Minworth and Curdworth, and that the Board apply to the Local Government Board for sanction to a loan of £8000 for the drainage of old lands and for the construction of covered carriers. All these recommendations were adopted, the covered carriers, it was explained by the chairman, having been designed at the suggestion of the engineer out of consideration for the public feeling of the neighbourhood.

WATER.

MALMESBURY Corporation has decided to purchase the local waterworks at the price of £6540, the price fixed by arbitration.

THE Crowland (Lincolnshire) Rural District Council, in order to improve the water supply of the town, has decided to commence boring for water, and an engineer has been instructed to carry out the necessary work. The Council is raising a loan of £1000 for the purposes of the undertaking.

THE St. David's Water and Gas Company announces an issue of 1507 ordinary shares of £5 each, upon which interest at the rate of no less than 4 per cent. is guaranteed until April, 1903. The city of St. David's has hitherto been both without water and gas, so that it is argued that this company, which has a capital of £16,000, has a good opening before it. The proceeds of the present issue will be devoted to constructing the authorised gasworks, and for laying gas mains in the principal thoroughfares of the town.

THE residents of Crossgates, Manston, and Stanks are supplied with Leeds water through Hunslet District Council; but, owing to the rapid development of the district, the supply is altogether inadequate now, the people at New Manston and Stanks having experienced a water famine of late. Some time ago the Water Committee of the Tadcaster District Council made arrangements with the Wetherby Water Company for a further supply at 9d. per 1000 gallons, but as the mains will not be constructed before the end of the year, it is stated the Water Committee has decided to erect a reservoir for storage purposes on Whitkirk Hill, by which route the Leeds water is taken. By this means it is hoped to temporarily relieve the necessities of the district.

THE Devizes Corporation has engaged a geologist to advise it as to a new water supply.

AT the last monthly meeting of the Greenock Town Council the Chairman said that in spite of the absence of rain during the past two or three months there was water in store sufficient to last until October.

CONSIDERABLE satisfaction has been expressed at Buxton that the water question has at length been amicably settled. Last week the Duke of Devonshire, K.G., received a deputation, headed by Mr. A. Brown (Chairman of the Council), Mr. C. F. Wardley, Mr. R. Hulme, J.P., the Clerk (Mr. Taylor), and Surveyor (Mr. Grieves), and the whole question was discussed. The details of settlement have not been made public, but the result of the interview with his grace has resulted in what may be termed a close to the dispute which has existed for so many months, and entailed considerable expense.

THE new waterworks constructed at Ruskington, near Sleaford, are now in working order, and at the meeting of the Urban Council last week, the Waterworks Committee reported that, although several houses in the town were without any water supply, the owners refused to bear the cost of laying the water on. It was resolved to levy a rate of 6d. in the pound to cover the initial outlay, and to take steps to compel all owners to provide their tenants with the new supply, unless they could prove to the satisfaction of the Local Government Board that they already possessed a satisfactory supply. The Council also resolved to prevent the retailing of the water to neighbours by those who had made the necessary connection with the main.

THE Select Committee of the House of Lords, presided over by Lord Hawkesbury, sat again last week to consider the proposed protective clauses, the preamble of the Leeds and Harrogate Water Bills having been passed by the Committee. The chief provisions of the agreement are that the Corporation shall not take the lands of Lord Masham, except such lands as are required for the construction of the works and reservoirs. If the Corporation wish the works protected from drainage, they can carry out the same themselves. The reservoirs shall be fenced round, and no barbed wire be allowed. A free supply of water shall be given to Lord Masham and his tenants. The Corporation shall replace the turf where it had been disturbed, and shall compensate the owners for any damage in the case of the bursting of the reservoirs. The Corporation abandon Healey Reservoir.

A LOCAL Government Board inquiry has been held at East Donyland recently into the Lexden and Winstree Rural District Council's proposal to borrow £3100 for purposes of water supply for the parish of East Donyland. The Council's scheme involves the purchase of the brewery lately in the occupation of Messrs. Daniell and Co., and it is claimed for that scheme that the supply of water there is pure and would meet the requirements of the place. The parishioners, however, do not look with favour upon the idea, and have armed themselves with an alternative scheme which they contend will be much more in the interest of the parish if adopted. They sent this to the District Council in the hope that it might be forwarded to the Local Government Board, but the District Council, having already submitted the brewery scheme, and having entered into a provisional contract for the purchase of the brewery—subject to the Local Government Board's decision on the matter—felt that they were unable to entertain the second scheme—whereat the parishioners of East Donyland have waxed exceeding wrath. Mr. Joseph Proctor, a member of the District Council's Committee appointed to consider the question of the Donyland water supply, said over the river at Wyvenhoe something like £1000 had been spent in borings, but here they had a fine supply of water without any risk.

THE Lambton Collieries Company are busy constructing two large reservoirs on the summit of West Herrington Hill, into which water will be pumped from the adjoining East Herrington Waterworks; and, when completed, it is anticipated that there will be a sufficient supply to provide for the whole of the inhabitants of the Herrington, Philadelphia, Shurney-row, and Fence Houses districts.

A BILL to confirm certain Provisional Orders of the Local Government Board came last week before the Examiners of the House of Commons for proof of compliance with the Standing Orders. There was no opposition at this stage, and the necessary formal proofs having been given, the Bill was ordered to be reported for second reading. Among other Orders was one authorising the Corporation of Newark to borrow an additional sum, not exceeding £20,000, for the purposes of its water undertaking.

EXCELLENT progress is reported with the new reservoir which Mr. L. P. Nott is building for the Llanelly Borough Council at Upper Llidi. The reservoir will have a capacity of 200 million gallons. The sum of £70,000 has been borrowed for carrying out the new works, and it is already quite clear that this will more than suffice for meeting the whole cost. Several economies in various directions have been suggested by the contractor and engineers, and Mr. Nott has also offered to complete the contract by March next for an additional £1000. By the terms of the contract the work is to be completed by July of 1902.

IT is worthy of note, says the *Bucks Herald*, that when the Rickmansworth and Uxbridge Water Bill came on for second reading in the House of Commons all the Bucks members spoke against it, and the fallacies of the measure were so clearly shown up in their speeches that it was thrown out by the House without the promoters even striving to take a division upon it. All the speeches were straight to the point. Mr. Grenfell, M.P. for South Bucks, showed the connection between the promoters of the Rickmansworth Water Bill and a leading London Water Company, and the disastrous effects that would follow the passing of the Bill to the localities affected. Mr. Carlile, in a clear and forcible speech, argued on behalf of the Bucks County Council, and demonstrated their reasons for opposing the measure. The member for North Bucks drove his points home in the lucid manner which his constituents appreciate, and clearly showed how the County Council, by opposing the Bill, were acting in the interests of the county. Mr. Rothschild urged geological reasons for opposing the measure, arguing that if it were passed the London Water Company would ultimately appropriate the water that belonged to Buckinghamshire. The result was eminently satisfactory, and the county may congratulate itself upon having three members who can fight its battles so successfully in the Legislative Chamber.

LIGHTING.

THE Stranraer Gas Company have decided to reduce the price of gas from 5s. to 4s. 7d. per 1000 cubic feet.

IT has been decided that a scheme should be prepared for the erection of a refuse destructor in conjunction with the intended electric station at Stoke-on-Trent.

BILLS to confirm certain provisional orders made by the Board of Trade under the Electric Lighting Acts, 1882 and 1888, relating to New Hunstanton and Wisbech, came last week before Mr. Lowther (Chairman of committees of the House of Commons). Formal evidence having been given, the Bill passed the committee stage, and in due course will be reported for third reading.

The Dorking Gas Bill has been read a third time in the House of Commons.

The Bill of the Bath Gas Light and Coke Company, which has been passed by the House of Lords, passed last week through its Committee stage without opposition, before Mr. W. J. Lowther, sitting as Chairman of the Committee of Ways and Means.

At a recent meeting of the Sub-Committee of the Electric Lighting Committee of the Edinburgh Town Council, it was reported that during the year just closed there had been applications for the electric light equal to 194,000 8 candle-power lamps. This, it was stated, far exceeded anything in the experience of the Committee.

The Bill confirming an order granted provisionally by the Board of Trade to enable the Urban District Council of Burgess Hill to lay distributing mains in Church-road, from the railway station to St. John's-road, Keymer-road, from the railway station to Ferndale-road and in Junction-road, from Keymer-road to Oakwood-road, and to break up certain other streets in the district not repairable by the Local Authority in the carrying out of the undertaking, passed through its Committee stage in the House of Commons, last week, without opposition.

Last week a special meeting of the Darlington Town Council was held to consider the question of continuing opposition to the Cleveland and Durham Electric Power Bill in Parliament. A resolution was adopted, on the proposition of the Mayor, seconded by Alderman Barron, that the Bill as amended in the House of Commons was considered unsatisfactory in the interest of the Corporation of Darlington, and that the sub-committee be consequently authorised to take measures to oppose the Bill in the House of Lords. There was no discussion in the open Council.

The growth of Ilford in Essex has been phenomenal. But a few years since it was a country village, now it is going ahead rapidly in those things that make a healthful and prosperous suburb. In addition to having acquired several public parks, it has gone in for an electrical undertaking costing about £70,000, and the light was on Saturday evening formally switched on by the wife of an ex-chairman of the Council, Mrs. Weeden, who was presented with a beautiful silver three-light table lamp. There are thirty-seven arc lamps of 1500 candle-power each, but residential streets are lighted with incandescent electric lamps. Within eighteen months it is expected that an electric tram service will be established.

A Local Government Board inquiry was held at Colchester last week with reference to the application of the Council for sanction to borrow £15,900 for electric lighting. Mr. A. R. Sillar, the Electrical Engineer, said they had overspent the last loan of £6500 to the extent of £664, owing chiefly to the fact that more meters were required and to the rise in the price of copper and cost of service mains. £6500 had been spent to meet the requirements of the consumers in service mains and professional fees. It was explained that £1970 5s. would be required for alterations to machinery necessary upon the proposed doubling of the voltage. The extension was necessary, because they had a great many more consumers than was anticipated; the change of voltage was necessary, because last winter during a heavy "load" the loss was found to be 7½ per cent. They were also to have electric tramways, and for these they would require an increase of power. It was intended to increase the number of accumulators, to re-wind two motors, and make alterations necessary for the higher voltage, &c. The rest would be for generating station extensions, building an underground water-feeder, purchasing new engine, feeder for the new barracks (£1260), &c. The sum of £3900 was for the purchase of the Osborne-street property adjacent to the electric light station.

The Watford District Council has decided to apply to the Local Government Board for sanction to a loan of £31,000 for the purpose of electric light works.

We understand that the Newcastle and Gateshead Gas Company has just contracted for its annual supplies of gas coal. The quantity required is between 130,000 and 140,000 tons, which has been distributed over several North Durham collieries at prices averaging about 9s. a ton delivered at the company's works, Redheugh. Last year the company had to pay as much as 16s. for its supplies.

Bills to confirm certain Provisional Orders made by the Board of Trade under the Electric Lighting Acts 1882 and 1888, relating to the electric lighting of Birstall, Shipton, and Honley, came last week before Mr. Lowther, Chairman of the Committee of the House of Commons. Formal evidence having been given, the Bills passed Committee, and in due course will be reported for third reading.

The Kensington Borough Council has contracted with the Kitson Lighting and Heating Syndicate for forty arc lamps, to be placed on one street, at a cost of £1581 for the posts and lamps, and £25 per lamp per annum for the current, which will make a total cost for the first year for the forty lamps of £2581. Similar terms have been made for two or three other streets in the same district.

For three years in succession, writes a correspondent, the Gas Light and Coke Company have applied to Parliament for powers to raise additional capital, and three times has Parliament refused to grant the request. In 1899 a Select Committee of the House of Commons recommended that the company should adopt a certain course which was calculated to benefit their gas consumers, but up till now the company have shown no willingness to adopt the recommendations; and in consequence of this Parliament has steadily refused to give further capital powers. The company's capital is now practically expended, and, apparently with the object of economising what little they have left as much as possible, they have intimated that they cannot any longer supply penny-in-the-slot meters. At present they have about 125,000 of these meters in use, but no more will be issued till the company have made their peace with Parliament at any rate. One consequence of this decision will be that thousands of the poorer classes in the company's area of supply will be denied the use of gas.

GENERAL.

At the last meeting of the Finsbury Borough Council a resolution was passed disapproving of the Shops Bill and the Shops (Early Closing) Bill, and the Town Clerk, Mr. G. W. Preston, has informed the Home Secretary, the London members of Parliament, and the other metropolitan Borough Councils of the decision.

The report of Mr. Clayton, the officer deputed by the Governor of the Straits Settlements to visit Christmas Island last year, deals mainly with the phosphate deposits, their working, and the condition of the labourers employed on them. At present only a very small space is being worked, but here the phosphate lies in blocks and is conveyed to the shore by trucks running on an inclined plane at the rate of 330 tons per day. Mr. Clayton enters in detail into the treatment of the labourers and others, of whom there are over 550. He describes their residences, food, wages, &c., and thinks the Phosphate Company deals very fairly with them; but he advises the employment of a resident magistrate and a fully-qualified medical man, and also an increase in the hospital accommodation. A Medical Officer has already arrived from England, and arrangements are being made for the permanent residence of a Government officer.

It is reported that a Bill is shortly to be introduced into Parliament which has the object of enabling Urban District Councils to advertise their districts as health resorts, and charge for that purpose against the general district rate a sum not exceeding the amount of a rate of a penny in the pound. The Bill applies only to England.

The popular West Somersetshire watering-place of Minehead wore a gay appearance on Saturday last, on the occasion of the opening of a new pier, which has been erected at a cost of £12,000. The opening ceremony was performed by Mr. George Fonnes Luttrell, of Dunster Castle. The new pier will enable passengers to land at nearly all tides.

The Streets Committee, at the last meeting of the Common Council (London), reported as to subsidences which had taken place in the carriageway of King William-street, Great Tower-street, and Eastcheap, and that these disturbances had been made good at a cost of £300. In answer to a question, the City Engineer said it was difficult to assign any exact reason for these subsidences, but they had probably arisen in consequence of the recent construction of tubular and other railways.

At a meeting of the Henstead Rural District Council held last week, the question of the contemplated extension of the sewage farm at Kirby Bedon by the Norwich Corporation was discussed at considerable length, and it was unanimously resolved that the Corporation Authorities at Norwich be informed that as the proposed extension would create a nuisance and be prejudicial to the health of the surrounding inhabitants, it would be their duty on its completion to take the necessary steps to have the same abated. In this the Council is desirous of preventing trouble and expense in the future both to themselves and to the Norwich Corporation.

The New Joint Fever Hospital for Dumbarton, erected on a site at Havock, by the Western District Committee of the County Council of Dumbarton and Dumbarton Town Council, was opened recently. The site on which the hospital stands is in a commanding position overlooking the Clyde, and extends to nearly five acres. The buildings consist of administrative block, two pavilions (each of two wards), caretaker's house, &c. The original cost was estimated at £14,000, but this had been exceeded. The plans were prepared by Mr. John M. Crawford, architect, Dumbarton, and the work was carried out under the care of Mr. G. Roxburgh, Inspector of Works. The wards are capable of holding forty-four beds. The sewage is to be treated by means of the septic tank principle.

The attention of the Halifax Special Sewerage Committee having been directed by the Local Government Board to the sanitary condition of the town, it made an inspection recently. At the end of Hollings-lane, at Old Causeway, and in Water-street, the sewage pipes were found well-nigh blocked with refuse, emitting most objectionable smells. The Committee then held its usual meeting. The Local Government Board had asked that the dry-weather flow in the sewage pipes should be verified, and that the Council should state what it intended doing with Sowerby. According to the latest letter, Sowerby, with a population of 3000, sends 70,000 gallons per day, while the estimate of the Sowerby Bridge flow is 130,000 gallons, and it has four times the population of Sowerby. Either Sowerby or Sowerby Bridge had made a mistake, and the question arises, "Does Sowerby really pay on the capital expenditure the Sowerby Bridge Council has provided for 70,000 gallons?" Sowerby has been asked to verify its figures. The suggestions in the letter of the Local Government Board will, we understand, mean an additional expenditure of some £10,000 to £12,000 more acreage being required at the sewage works at Milner Royd.

It is gratifying to announce that small-pox is abating in Dundee. There were fourteen cases in hospital last week, none of a virulent type, and it is expected most of the patients will be discharged shortly. There are no inmates in the temporary reception house. The precautionary measures which have been adopted by the Medical Officer and the sanitary department have not been relaxed in any way, and unless another outbreak occurs the city will be clear of the malady very shortly.

The insanitary condition of Broadstone, a question that was ventilated at the last meeting of the Poole Rural District Council, is giving rise to considerable anxiety on the part of the inhabitants and those who are interested in the health of the district. If there are bye-laws dealing with cesspools, then it should not be necessary for moral compulsion or pressure to be exercised in order to make the Council take steps to carry them into effect. Familiarity with unpleasant facts sometimes tends to blunt the powers of perception, but the condition of affairs at Broadstone is by no means either to be desired or commended.

After many months of hard work by the Local Committee, we are glad to know that South Londoners are now assurred of the additional 43 acres being added to Brockwell Park. The whole of the sum required, £66,800 odd, has been promised, the London Parochial Charities having offered a further generous contribution. For rescuing this beautifully wooded land from the hands of the enterprising jerry builders, London is indebted to the London County Council, the Municipal Bodies of Lambeth, Camberwell, Newington, St. George-the-Martyr, and Southwark, the Ecclesiastical Commissioners, the London Parochial Charities, the Peabody Donation Fund, the Commons and Footpaths Preservation Society, Mr. H. C. Gooch, and the Skinners', Goldsmiths', Merchant Taylors', Drapers', and Armourers' Companies; also to many generous donors towards the necessary working expenses.

At a recent meeting of Bo'ness Town Council, the Special Committee appointed to negotiate with proprietors in the insanitary area in the centre of the town, reported that they had come to terms with certain of the proprietors in the Vennel. Property of the value of some £2000 had been purchased, and improvements at this narrow dangerous part of the street would be gone on with immediately. As the whole of the properties in the scheduled area must be purchased before 13th July, 1902, the Town Council granted authority to the Committee to negotiate for the acquisition of the rest of the properties. It was agreed to borrow on temporary loan, and that a permanent loan be afterwards negotiated, payable in fifty years. It was resolved that the authorised borrowing for the street improvement at North-street be raised from £4500 to £5300, and that this sum, less the £2300 already borrowed, be got on temporary loan.

The question of watering the streets of Newport now that the dust is very much in evidence occupied the attention of the Corporation recently. Mr. J. Liscombe voiced the feelings not only of the tradesmen in the main streets for keeping down the dust which now spoils their stocks, but also the wishes of those in the streets where private residents live. The Chairman of the Sanitary Committee said at present the main streets were watered once a day, and those who used the streets for vehicular traffic had a strong objection to more watering than that. Mr. A. E. Parfitt suggested that the streets be washed early in the morning. It was like a Johannesburg dust storm at times in the main streets, and drapery goods especially were spoiled. Mr. F. Phillips suggested that the streets should be swilled from fire hydrants. Alderman Jones said the matter would be tried as an experiment, but the Sanitary Committee had been informed by the Waterworks Committee that the reservoirs were running down.

The enormous cost of vaccination under the new Act is, we understand, causing some concern among metropolitan poor law unions. In West Ham, for the year 1898 the amounts paid to Medical Officers was only £289 12s. 10d., and to the vaccination officers £311 8s. 3d. Last year, under the new Acts, the amount paid to the public vaccinators was no less than £2242 4s. 6d., while the vaccination officers received fees amounting to £647 4s. 3d., the amount paid to each of the two officers being £31 and £30 respectively.

The Institute of Preventive Medicine is at length installed in its new building near the north-east corner of Battersea Park, but we learn that the "vivisectionists" are not to have the field all to themselves in this neighbourhood. At the opposite corner of the park a large house, locally known as "The Folly," which has many years remained without a tenant, has been acquired by the Anti-Vivisection Society, and is now undergoing extensive alterations with a view to its opening shortly as an "Anti-Vivisection Hospital."

A special meeting of the Sanitary Committee of the Llanelly Urban Council was held last week to draw up replies to give to Local Government Board inquiries in respect of the housing of the working classes in the district. Messrs. T. Hughes and Joseph Williams remarked that there was a distinct want of housing accommodation in the town for labourers receiving from 18s. to 22s. per week. There were plenty of houses at 5s. and 5s. 6d. per week. It was decided to give the answer, and to say that the question of making provision under the Act was under consideration.

At a special meeting of the Bath Surveying Committee, a report was considered from the Scavenging Committee with regard to the alteration of the destructor. Alderman Taylor said it was absolutely necessary that the work should be got on with at once. Mr. Fortune had prepared a report which dealt with the question of introducing forced air draught. The work could be done for £1242, and the Scavenging Committee recommended the acceptance of a tender by Messrs. Goddard, Massey, and Warner. This recommendation was agreed to, and a meeting of the Urban Sanitary Authority will be held shortly to confirm it.

Sir Kenelm Digby, Permanent Under-Secretary at the Home-office, presided at a conference last week to consider representations from persons engaged in the tanning industry and other trades involving the handling of hides as to the Home-office rules for the protection of workmen from infection by anthrax. Mr. W. L. Jackson, M.P., was among the speakers, and it was pointed out that the wearing of gloves was an impediment to work, and that a garment fitting tight at the wrist and at the neck would be sufficient protection. Other matters were referred to, and Sir Kenelm Digby promised that all the suggestions made should be considered before any further rules were made.

National Health Society.

OFFICIAL TRANSACTIONS.

Sanitary Inspectors' Examination.—It is satisfactory to note the success of the Society's students in the recent examination held by the Sanitary Inspectors' Examination Board. As before, the majority of the female candidates were students from the National Health Society, and all these ladies were successful in obtaining the certificate. The names thus added to our list of successful students are as follows:—Miss Adeline E. T. Biggs, Mrs. Theodora Fisher, Miss Madeleine Stampa, Miss Anne Hutchinson, Miss Florence Potter.

PERSONAL.

Mr. A. A. Piccaven has been reappointed Inspector of Nuisances for Long Sutton, at the same salary.

Dr. Boustead has just resigned his position as Medical Officer of Health for Hexham, after eleven years' service.

The salary of Mr. Wm. Gray, as Distribution Engineer to the Birmingham Water Committee, has been increased from £300 to £400 per annum.

Dr. C. Killick Millard, Medical Officer and Public Analyst for Burton-on-Trent, has been appointed Medical Officer of Health, Superintendent of the Isolation Hospital, and Public Analyst for Leicester.

Dr. Richardson has been reappointed Medical Officer of Health for Eppingham for six months.

Mr. T. W. Witts has been reappointed Inspector of Nuisances for East Alton, for one year, at a salary of £60 per annum.

Mr. C. W. Thompson, the present Surveyor for Ripley, has been appointed Inspector of Nuisances at a salary of £60 per annum.

The Local Government Board has approved the appointment of Dr. Scott as Medical Officer of Health for Castle Donington.

Mr. William Tedham, of Tunbridge Wells, has been appointed temporary Sanitary Inspector for Woolwich for six months, at a salary of £120 per annum.

Mr. J. A. Gray, of Cumberland, has been appointed gas manager to the Teignmouth Corporation. There were fifty-five applicants for the post, to which is attached a salary of £150 per annum.

Dr. A. Wellesley Harris, Medical Officer of Health at Southampton, has been unanimously appointed as Medical Officer and Analyst to the Metropolitan Borough of Lewisham, at a salary of £800 per year.

The Chief Inspector of Factories has appointed Dr. A. C. K. Turner to be certifying surgeon under the Factory Acts for the Fairford District of Gloucestershire, and Dr. E. F. Clowes for the Wootton-under-Edge District.

Mr. Thomas W. Dee, son of Mr. T. G. Dee, treasurer of the Sanitary Inspectors' Association, has passed the examination of the Sanitary Inspectors' Examination Board, thus qualifying himself for an appointment as Sanitary Inspector. He has already taken honours in plumbers' work under the City and Guilds of London Institute.

After a brief illness the death has just occurred of Mr. J. M. Brydon, vice-president of the Royal Institute of British Architects. In London he designed many public buildings, and at the time of his death was architect of the new Local Government Board and Education Department building that is being erected in Whitehall at the corner of Parliament-square.

We regret to record the death of Dr. Robert Skimming, which took place after a long illness at his residence, Trevor Lodge, East Molesey, on Thursday week. Dr. Skimming, who was 58 years of age, had been suffering for some years, but the end came somewhat suddenly. He was M.D. Edinburgh, 1864; F.R.C.S. 1873 (L.M. Univ.), and R.C.S. Edinburgh, 1864, and a member of the British Medical Association. He went to East Molesey over thirty years ago, and succeeded the late Dr. Rowlands as Medical Officer of Health under the Local Board. He was also Vaccination Officer and Poor Law Medical Officer for their district, and Medical Officer to Court Good Intent Ancient Order of Foresters for many years. He retired from these public offices in 1892. He was the author of a well-known medical work on epilepsy. He leaves a widow, one son (who is in New York), and three daughters, for whom much sympathy is felt.

CONSTRUCTION OF ROADS AND STREETS IN GIBRALTAR.

We gather from the Annual Report of Dr. H. P. Elkington, Medical Officer of Health, Gibraltar, that the roads and streets of the colony have been constructed of three different materials, viz.:—(1) Limestone macadam, (2) wood, (3) concrete. Macadam roads had been constructed throughout the colony, but for various reasons were replaced by wood and concrete in the principal thoroughfares of the business portion of the city. The macadam roads still existing, such as are vested in the Commissioners, are good, and maintained in satisfactory condition; but on steep gradients they are at times found to be slippery; this is a condition said to be inseparable from the limestone used in their construction when watered by sea water. Nevertheless, from a sanitary point of view, the roads constructed in this manner, when satisfactorily cleansed and maintained, are far superior to other formations of a more expensive character.

The wood pavements have proved to be quite unsuitable in this climate; they absorb the urine, &c., from animals, and in consequence throw off in hot weather a most disagreeable smell, and the dust from them is most injurious. They appear not to be durable, and are said to be twelve times as costly in construction as other forms which are more suitable.

The concrete roads are rough, noisy, and expensive. It would appear that the Commissioners do not contemplate repeating the experiment of covering the surface of their streets with this material.

During the last few months a new form of pavement has been introduced into the colony, known as "Tar Macadam." This is noiseless, impervious, free from dust in summer and mud in winter, is easily cleaned, and forms a really effective sanitary paving. It is understood that the Commissioners are trying it as an experiment in this climate, as it cannot be positively stated what effect the sun may have upon it in the hot months. If it stands the test of the summer satisfactorily, its advantages are so great that it is to be hoped it will be used to replace the insanitary wood pavements with as little delay as financial considerations will permit.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2209.—Houses for the Working Classes: Book Containing Plans.—"J. E. H." writes:—"Can you refer me to any publication giving reliable advice as to the building of healthy working-class cottages? Information is required as to general plan, and good but inexpensive sanitary fittings."

Answer.—The best book on the subject is undoubtedly Cranfield and Potter's "Houses for the Working Classes in Urban Districts," comprising thirty typical and improved plans arranged in groups, with elevations for each, and block plans, &c., also introductory and descriptive text, general notes on planning, tables giving sizes of rooms, cubic contents, cost, &c.; price 15s. 9d. post free. For a reliable book on sanitary fittings as asked for, Jensen's "House Drainage and Sanitary Fitments," price 5s. 3d. post free. Either of the books may be obtained from the office of this journal.

2210.—Combined Drainage: Premises Within Same Curtilage.—"Inspector" writes:—"A combined drain receiving the drainage of three cottages, belonging to one owner, as in accompanying sketch, is in a defective condition, and a nuisance is caused on adjacent premises. The owner of the combined drain has been served with a preliminary notice to repair the drain, but disclaims all liability, and refers us to Section 4 of the Public Health Act, 1875. Will you please advise as to who is responsible?"

Answer.—The combined drain receives the drainage of three houses within the same curtilage, and it is a drain repairable by the owner. See Pilbrow *v.* St Leonard's, Shoreditch, 1 Q.B. 33, 59 J.P. 68. The Authority should serve notice upon the owner under Section 41 of the Act of 1875, and on his default execute the work and recover the cost.

2211.—Sale of Food and Drugs Acts: Skimmed Milk, Proceedings.—"J. P. H." writes:—"An Inspector appointed under the Sale of Food and Drugs Acts asked for a pint of milk, and was served. He divided the sample. The analysis certified it was deficient in butter fat to the extent of 12 per cent. A summons was issued under Section 6 of the Sale of Food and Drugs Act. The justices dismissed the summons, contending that to have succeeded the Inspector must ask for new milk, basing their decision on Lane *v.* Collins. Can you inform me if there is not a more recent decision wherein it is held that an Inspector is not obliged to ask for 'new milk' to succeed under Section 6?"

Answer.—In the case of Lane *v.* Collins, 14 Q.B.D. 93, 49 J.P. 89, proceedings were taken under Section 6 for that the respondent who was asked by Lane, appellant, for milk, and was supplied with skim milk, and a metropolitan police magistrate had refused to convict on the ground that Collins had committed no offence within the 6th Section, inasmuch as Lane had asked for milk, and got milk, but milk which had been skimmed; and this decision was upheld on appeal. The proceedings in such cases should, however, be taken under Section 9, which provides that "no person shall, with intent that the same may be sold in its altered state without notice, extract from any article of food any part of it so as to affect injuriously its quality, substance, or nature, and no person shall sell any article so altered without making disclosure of the alteration," and should not be taken under Section 6. The querist does not state whether the vessel containing the skimmed milk was labelled as required by Section 11 of the Sale of Food and Drugs Act, 1899. If this was not the case, proceedings should be taken under both of the sections referred to.

2212.—Combined Drainage, Drain or Sewer, Cesspool and Gully: Meaning of Terms.—"Inspector" writes:—"(1) I enclose sketch showing a block of houses owned by one owner. Your opinion is asked as to whether the main drain is a sewer, and for the cleansing and maintenance of which the Council is responsible. Would the vesting be different if the houses belonged to several owners? (2) Please define the difference between a cesspool and a gully, or what is the meaning of the term cesspool in the scavenging clauses? Should I take it that before the Public Health Act, 1875, was passed that a trapped gully was unknown, and that the gully has replaced the cesspool within the meaning of the Act?"

Answer.—(1) From the sketch submitted it appears that the whole of the houses have one common backyard, in which the main drain and other drains are laid. The houses are within the same curtilage, and the combined drain is consequently a drain and not a sewer. See Pilbrow *v.* St. Leonard's, Shoreditch (1895), 1 Q.B.D., 433, 59, J.P. 68; St. Martin's-in-the-Field *v.* Bird, 1 Q.B.D., 420. The duty to cleanse and repair will be on the owner. (2) A cesspool is a well constructed below ground level to receive the sewage from a house or number of houses. It is not supposed to be provided with an overflow. A gully is a small chamber formed usually in one piece of iron or stoneware for the reception of sink wastes, rain-water, &c., and is connected to a drain, into which the contents are delivered. It should be trapped and provided with a grating over it. Gullies of iron and stoneware are, of course, now used to receive the washings from streets. The querist's surmise that the gully has replaced the cesspool is not correct. Cesspools still exist in most rural districts.

2213. — Smoke Nuisance from Workshop Stove. — "Inspector" writes:—"Will you please advise as to whether a Local Authority are enabled to take proceedings against a cooper for an alleged nuisance caused by smoke emitted from an ordinary stove in his workshop used for warming the room, and in which he frequently burns his waste material? The chimney to this stove is no higher than the bedroom windows of two adjacent houses, and when the wind is in a particular direction the occupiers have had to close their doors and windows on account of the above."

Answer.—The Local Authority may institute proceedings under Secs. 94 to 96 of the Act of 1875, the offence being that defined by Sub-sec. 7 of Sec. 91, of not consuming the smoke arising from the combustible used therein.

2214. — Houses Draining into Cesspool: Easement.—"C. H. C." writes:—"A field and four cottages have been sold to two separate purchasers. A has purchased the field, and B has purchased the cottages adjoining. In the field there is a cesspool (now full), into which the four cottages drain. The Local Authority have served notices, separately, upon A and B to cleanse the cesspool. Please advise (1) who is liable, A or B?

NEW WORK BY W. J. DIBDIN, F.I.C., F.C.S., F.S.I., &c.

NOW READY. 219 pp., Cloth, Gilt. Price 5s. Net.

LIME, MORTAR, & CEMENT:

THEIR CHARACTERISTICS AND ANALYSES, WITH AN ACCOUNT OF

ARTIFICIAL STONE & ASPHALT

By W. J. DIBDIN, F.I.C., F.C.S., F.S.I., &c. &c.,

Formerly Chemist and Superintending Gas Examiner to the Metropolitan Board of Works and London County Council.

PRESS OPINIONS.

"A very useful little treatise. . . . It deals with the character and chemical composition of the various materials used in making mortars and cements, and the methods and results of their chemical analysis. . . . We recommend this book not only as an excellent text-book for students, but also as a practical treatise for practical men."—*British Architect.*

"There has certainly been need for a book dealing with calcareous structural materials from the builder's and architect's point of view. Questions of the quality of lime and of cement, of the composition of mortar, of the suitability of diluents, such as sand and gravel, come frequently before the members of this trade and profession, who have to pronounce upon to the best of their ability. The author has succeeded in putting together a number of useful statements—especially to be commended is his dissertation on mortar. The section on asphalt, embodying Mr. Clifford Richardson's researches, will be acceptable."—*The Engineer.*

(2) If B undertakes to cleanse (and he seems inclined to shift it on to A) can A ask for compensation in respect of passing over his land, opening up, &c. (3) May A fill up the cesspool (of course by giving notice), or prevent the drainage from being discharged on to his property?"

Answer.—(1) The owner of the cottages will be liable. (2) Both A and B have purchased the properties, subject, we think it will be found, to the easement of the drain and cesspool on A's land. B should refer to the deeds of his property, which will contain a clause relative to the easement, but apart from this we should say that an easement has been acquired, and B will have a right of passage to the cesspool over A's land for the purpose of emptying it. Compensation will be payable only if damage be created. (3) No.

2215.—Petroleum Acts: Whether Sanitary Inspector can be Required to Carry Out Duties of Inspector Under.—"M. S." writes:—"Can a Rural District Council compel their Inspector of Nuisances, who was originally appointed without such duties, to carry out the duties of Inspector under the Petroleum Acts without additional remuneration?"

Answer.—If the Inspector of Nuisances was appointed subject to the General Order of the Local Government Board of the 23rd March, 1891, and half his salary is repaid by the County Council, the Local Authority are not entitled to require him to carry out the duties of Inspector under the Petroleum Acts without additional remuneration. The officer may himself appeal to the Local Government Board by letter on the subject, and ask for their guidance.

2216.—Insufficient Drainage: Property Changing Hands after Notice.—"J. W." writes:—"Notices were served some time ago by this Urban District Council under Secs. 36 and 41 of the Act of 1875 on the owners of two contiguous houses, the drainage of both houses being conveyed through one house; one of the owners commencing carrying out the work before obtaining the consent of the adjacent owner. The latter has now sold his house to the owner of the one who had carried out the notice. the property being sold with the declaration that a notice had been served by the Sanitary Authority. One person now belongs to the two houses, and he declines to do the work, alleging that that which was formerly a drain is now a sewer. Will you please advise what position my Authorities are in

Answer.—At the time of service of the notice the drain was a private drain, repairable by the owners. The notice, in our opinion, still holds good, and the Local Authority may do the work on the owner's default, and recover the expenses.

2217.—Public Slaughter-houses: Slaughtering in Private Premises.—"E. R." writes:—"In this urban district a public slaughter-house was erected some years ago by the Sanitary Authority. Several of the butchers have now commenced complaining of the buildings and the rules, and have tried to erect private slaughterhouses for themselves within the Borough, but have been refused. Recently one of them has commenced to slaughter on a farm outside the Borough, and he brings the carcase to his shop in town. Your opinion is therefore kindly asked what power, if any, has the Urban Authority in the matter? What powers have the Rural Authority in whose district the farm is situated, to prevent this or any other building from being used as a slaughter-house?"

Answer.—The Urban Authority may prevent the erection or use of any building intended for a slaughter-house, by refusing to grant a licence for the erection or use of any such building. They are unable, however, to prevent the erection and use of slaughter-houses or buildings used as such outside their own district. The Rural Authority, if they do not already possess Model Bye-laws with respect to slaughter-houses, might be asked by the Urban Authority to adopt bye-laws for their district appertaining to slaughter-houses. The Rural District Council may be invested under Sec. 276 of the Act. of 1875 with the powers of an Urban District Council under Sec. 169 of the Act, to make bye-laws and control slaughter-houses within their district.

2218.—Public Highways: Footway Improvement.—"Surveyor" writes:—"In my district, which is an urban one, it is proposed to construct and pave a footway alongside the old highway which passes through the town. This highway is about 25ft. wide, and alongside it, but set back about 7ft., were built—some of them fifty years ago—dwelling-houses. It was evidently intended that a pavement should be made along the front of the houses. This, however, has only been carried out by a few owners. The Council have now adopted the Private Street Works Act, 1892, and I have prepared plans for a 6ft. pavement along the front of these houses. Will you kindly advise who may be required to pay for the paving—the owners of the houses, or should the Council do the work out of the rates?"

Answer.—It would have been helpful to us if we had been furnished with a plan of the proposed work, and also one showing the conditions as now existing. It appears to us, however, that the owners cannot be required to contribute to or bear the cost of the footway paving. From the informatien given it does not appear that the 7ft. strip has been dedicated as a public highway. The Council should do the work and charge the cost to the district fund.

THE CONSTRUCTION OF ROADS, PATHS, AND SEA DEFENCES.

By Frank Latham, C.E.

(Borough Engineer and Surveyor, Penzance. Author of "The Sanitation of Domestic Buildings," &c.)

CHAPTER I.—INTRODUCTION.

There are few questions which have such a practical bearing on the progress of a nation, the advancement of civilisation, the furtherance of knowledge, and the numerous advantages to be derived from easy intercourse between all parts of a country, as that of the effectual construction and maintenance of roads.

It is a matter of much importance in these days of competitive industry and increasing needs of commerce, bringing in their wake the ever-growing demand for increased facilities of exchange and transport, and the more extensive adoption of modern modes of locomotion, that all roads should be constructed in the most efficient manner, so as to best conform to the requirements of the times; thus their durability of construction and those conditions necessary for safety and ease in travelling should be carefully considered, and the best course adopted, thereby reducing as much as possible the amount of wear and tear to horses and vehicles, and at the same time contributing to the comfort of those whose business causes them to be "on the road."

The economies derived in a system of good roads over even secondary ones must be considerable, but when compared in these days with the bad roads of a century or more ago, the saving to the public must be enormous, besides abolishing an inconvenience which would be absolutely intolerable to the high standard of excellence expected by the public at the present day.

Sir Henry Parnell says:—"The measures necessary to be taken for affording the means of travelling with rapidity and safety, and of transporting goods at low rates of carriage, form an essential part of the domestic economy of every people. The making of roads, in point of fact, is fundamentally essential to bring about the first change that every rude country must undergo in emerging from a condition of poverty and barbarism. It is, therefore, one of the most important duties of every Government to take care that such laws be enacted, and such means provided, as are requisite for the making and maintaining of well-constructed roads into and throughout every portion of the territory under its authority."

In populous districts, large towns, and health resorts, it is of paramount importance, apart from the desirability of good roads for traffic, that all roads and back courts should be maintained in a proper state of repair, from a sanitary point of view. A residential district with bad and neglected roads and courts cannot be regarded as healthy. Cleanly roads in proximity with dwellings play an important part in the sanitary education of the inhabitants, and no dwelling can be regarded as perfectly sanitary, especially in crowded localities, when abutting on neglected and, perhaps, narrow, sunless, and inefficiently-drained roads.

Since the introduction of railways there is practically greater demand for good roads in and about towns than was previously the case, the fact that railways have set in motion the whole of the people and commerce calling for the provision of the best facilities for transportation to and from these main centres and arteries of the country.

It is by means of the railways that so many thousands of persons flock to the seaside towns and other health resorts at various seasons of the year, calling forth in no small degree the construction of beautiful roads, promenades, and drives, sometimes entailing much engineering skill and considerable outlay of money.

The railway has, by its rapid conveyance of commerce and passengers from one locality to another, placed the remotest parts of the country within easy touch with the great centres, and has been the means of opening out many delightful and hitherto unfrequented districts, all in their turn requiring improved means of intercommunication.

As the earlier history of the advancement of road making in England is interesting, it is as well that before entering on to the present methods of construction, that an outline of the past should be briefly sketched.

The Carthaginians have the credit for the invention of paved roads. The Romans, who were in touch with the Carthaginians from about 500 years B.C., became well instructed in the art of road making, and in the year 312 B.C., Appius Claudius partly constructed the most noble of Roman roads, named after him the Via Appia, or Appian Way.

The interest taken in the construction of roads by the Romans was exceedingly great, so much so that under Augustus and Julius Cæsar all the principal cities and towns were made to communicate with Rome by paved roads, which work was followed by numerous similarly constructed roads communicating throughout Europe and continuing through neighbouring continents and islands, the direct lines of the great roads being maintained from shore to shore.

Mr. Tredgold says:—"The Roman roads ran nearly in direct lines; natural obstructions were removed or overcome by the effort of labour or art, whether they consisted of marshes, lakes, rivers, or mountains. In flat districts the middle part of the road was raised into a terrace. In mountainous districts the roads were alternately cut through mountains and raised above the valleys, so as to preserve either a level line or a uniform inclination. They founded the road on piles where the ground was not solid, and raised it by strong walls, or by arches and piers where it was necessary to gain elevation."

Pinkerton's Geography contains the following remarks on the Roman roads of England: — *The Roads of England*, "which may still be traced in various ramifications, present a lasting monument of the justice of their conceptions, the extent of their views, and the utility of their power. A grand trunk, as it may be called, passed from the south to the north, and another to the west, with branches in almost every direction that general convenience and expedition could require. What is called Watling-street led from Richborough in Kent, the ancient Rutupiæ, northeast through London to Chester. The Ermine-street passed from London to Lincoln, thence to Carlisle, and into Scotland. The Foss way is supposed to have led from Bath and the Western regions, northeast, till it joined the Ermine-street. The last celebrated road was Ikeneld, or Ikneld, supposed to have extended from near Norwich, southward, into Dorsetshire."

Upon the Roman power being broken up, their successors allowed the roads to fall into a bad state of repair, in fact cared little or not at all for them, so that in course of time these magnificent roads were practically ruined by absolute neglect and contempt.

It was not until comparatively recent date that successful road-making was practised by modern nations. England and France gave but very little attention to the construction and repair of roads until about the 17th century. Prior to this time the roads of this country were allowed to remain in the most disreputable condition, and in some places almost impassable. As recent as 1770 a publication by Mr. Arthur Young, describing his tour in the North of England, gives some very striking accounts of the state of the roads at that time. In describing some of the turnpike roads, he explains that the road from Wigan was so bad that

he measured ruts in its surface 4ft. in depth, and that the road's surface is mended merely by "tumbling in some loose stones, which serve no other purpose than jolting a carriage in the most intolerable manner." The road to Newcastle appears to have been even worse than the Wigan one. Mr. Young says:—"A more dreadful road cannot be imagined," and that he was obliged to hire two men at one place to support his chaise from overturning. He says:—"Let me persuade all travellers to avoid this terrible country, which must either dislocate their bones with broken pavements, or bury them in muddy sand."

Mr. Thomas Codrington, in his work on "The Maintenance of Macadamised Roads," says:—"On the ordinary highways, improvement was hindered by the system of statute duty, and by parish management under a person chosen yearly to serve the office of surveyor of highways. Everyone who kept a team of horses was liable to be called upon to do six days' team work, and those who did not keep horses paid money instead. The parish surveyor generally had no special knowledge of road repairing, and the team labour and other work were seldom well applied."

Under this system the responsibility of maintaining roads near towns or between towns would come very heavy upon those few persons who were expected to provide the funds for carrying out the necessary repairs.

The first attempt to improve the highways was by the introduction of the turnpike system.

The first turnpike road was established by law in 1653, by means of which a toll was imposed upon all but pedestrians that passed through the gate. This toll was then used for purposes of road-making. It appears, however, that the people were prejudiced against the system of toll gates, and that for many years the turnpikes were few.

At the end of George the Second's reign the system was put into more general operation throughout the country.

It was, therefore, the end of the 18th century before any marked improvement was made in the defective state of the roads.

The following extract from an essay on the "Construction of Roads, dated 1813," by Mr. Edgeworth, will show the defective condition of roads that existed even in the early part of the 19th century. Mr. Edgeworth says:—"In many parts of this country, and especially near London, the roads are in a shameful condition; and the pavement of London is utterly unworthy of a great metropolis."

Early in the 19th century rapid changes began to take place in road making, largely due to the labours of Metcalf, Telford, McAdam, and others.

Mr. McAdam, in his "Remarks on the Present System of Road-making," says the then existing practice of making a road in England and Scotland was "to dig a trench below the surface of the ground adjoining, and in this trench to deposit a quantity of large stones, after this a second quantity of stones, broken smaller, generally to about 7 lb. or 8 lb. weight; these previous beds of stone are called the bottoming of the road, and are of various thicknesses according to the caprice of the maker, and generally in proportion to the sum of money placed at his disposal. On some new roads made in Scotland in the summer of 1819 the thickness exceeded 3ft. That which is properly called the road is then placed on the bottoming by putting large quantities of broken stone or gravel, generally 1ft. or 1ft. 6in. thick at once upon it, and from the careless way in which it is done the road is as open as a sieve to receive the water which is retained in the trench, whence the road is liable to give way in all changes of the weather."

(*To be continued.*)

INFECTIOUS DISEASES, DISINFECTION, VENTILATION.

By W. Arnold Evans, M.D., Medical Officer of Health, Bradford.

(*Concluded from page* 465.)

Although it is the safest plan to consider that anyone suffering from a fever is equally infectious during every period of its course, yet there are stages in the course of some affections in which the poison seems to be more powerful than at others; in measles and whooping-cough the infection is very powerful at the onset of the disease, which fact is one reason why these infantile affections are so difficult to control, one child becomes infected almost as soon as, or before, the affection in another child has been recognised.

In diphtheria one must regard the patient as infectious for as long as any of the characteristic bacilli can be cultivated from the mucous membrane in the throat. In scarlet fever the infection may remain for a long time—indeed, it is difficult to say when people who have suffered from scarlet fever may with safety mix with their fellows; at any rate, they remain infectious for as long as the skin peels or there is any discharge from the ears or nose.

Now the behaviour of disease-producing organisms in bringing about the conditions peculiar to any disease is not always the same. The microbe may enter the body through some delicate membrane, gain access to the blood stream and multiply rapidly, and so cause the symptoms characteristic of its presence. As an example of this method of infection I may mention those diseases which generally are known as "blood poisoning" and relapsing fever, or, the bacillus may enter an organ of the body, may remain there and set up an inflammatory action, resulting in a perversion of tissue growth with consequent tissue death and the formation of abscesses and cavities, *e.g.*, phthisis. Or, again, it may become attached to the surface of a mucous membrane, multiply, and produce a poison which is absorbed as in diphtheria.

Now the germ theory of disease is closely allied to the question of immunity, and immunity may be either natural or acquired. By *natural* immunity I mean that some animals are not liable to be infected by a bacteria that would produce a disease in others. This immunity depends upon several conditions, some of which are not known, but at the same time is only a relative term; for if a few bacteria only are introduced into the body, no untoward result may follow, but if large quantities are introduced the result may be disastrous.

But immunity may be *acquired*, *i.e.*, produced artificially. For a number of years persons are rendered immune to small-pox by vaccination, and so in many other diseases, *e.g.*, diphtheria and plague. Immunity may also be induced by previously bringing on a mild form of the disease.

The first duty of a Sanitary Inspector on becoming aware of an outbreak of infectious disease is to visit the house and make an examination of the interior and exterior in a manner described last week by Dr. Cameron. But let not the Inspector rely on a Compulsory Notification Act to give him the information, for some cases are not notified at all, on account of the absence of medical attendance, and such cases are frequently the starting-point of an epidemic which afterwards gives trouble. Having become acquainted with the existence of a case of infectious disease, inquiry should be made in the neighbourhood to find out if there exist other cases in the district, and very frequently the School Attendance Officer can give valuable information in this respect.

Always look to the water supply, for this is fre-

quently the cause of illness, particularly in country districts.

The school attendance must be ascertained, together with any such important fact of there being a considerable number of children away from a particular school from the same illness.

You should inquire closely into the milk supply, for milk is a very potent medium in the spread of infectious disease. Epidemics of scarlatina, enteric fever, and diphtheria are frequently caused by infected milk supplies. You must, of course, make inquiry as to the method of excrement disposal, whether it be by water-closet or privy midden; the conditions of sinks, gullies, and drains. Finally you should be on the alert for the existence of nuisances due to the keeping of animals or accumulations of filth.

Another set of duties relates to the isolation of the infected person and the final disinfection of the house. In the matter of isolation you must exercise tact and discretion. Remember that an Englishman's house is his castle, and that undue interference is likely to be resented. Never enter a bedroom of a sick person; it is not necessary, and any information you require can be got without doing so. In some cases, such as one-roomed dwellings, one must enter the bedroom, but in houses consisting of several rooms it is not advisable to do so.

Ascertain whether some one person is told off to look after the patient, and whether the necessary precautions are taken to prevent this person mixing with other people. You should give instructions as to the proper use of disinfectants, and how to treat infected articles. Give detailed instructions in full. I think the best method is to leave a printed bill, but be sure the advice contained in it is put as concisely as possible, for if the bill be a long one people will frequently not take the trouble to read it.

Other points are to find out with whom the patient has been associating since he became infectious, and keeping these under observation for the necessary period of "quarantine;" the presence in the house of books belonging to a public library, which should be removed and destroyed, or disinfected.

If your inspection has led you to suppose that there is any condition which is unsatisfactory, you should issue proper notices to secure the abatement of the nuisance or nuisances, and see that the terms of your notices are complied with.

All the remarks I have hitherto made, whether as to the discovery of the cause or the prevention of the spread of the disease, have had reference to facts coming under your notice as a result of the first visit. But you have afterwards to keep an eye upon the invaded house for a variable time. If the patient is being treated at home you may have to pay visits for a good many weeks, and those visits should be regular and frequent. It is impossible for me to say how frequent, because that will depend upon the particular disease, upon the precautions that are being taken, and upon the likelihood, in your judgment, of your instructions being properly carried out. At any rate, they should be regular and sufficiently frequent to ensure your seeing how your directions are attended to, and I think you will do well to remember that the time when you ought to make these visits oftenest is towards the *end* of the infectious period, for after two or three weeks people begin to be careless. Every subsequent visit is advantageous, not only in the way of enabling you to see if your instructions are being carried out, but also by enabling you to find out if any further cases have occurred in the same house. You should always make quite sure that if there is any further occurrence of the disease it does not escape your notice.

Lastly, you have to perform the final disinfection of the invaded house.

DISINFECTION.

The process consists in the killing of the various micro-organisms, which are the cause of infective diseases. No process can be considered efficient unless it is a real germicide, and not an agent which will merely prohibit temporarily the growth of germs. A bad disinfectant is worse than none at all. I am afraid that in the popular estimate a disinfectant is often considered to be a substance which, by its own powerful smell, will disguise an odour which is more offensive. This is not disinfection, and the agent used should be spoken of as a "deodorant," but not a "disinfectant."

The principal forms of disinfection are three, viz.:—

(1) *Heat*, by hot air, steam, or boiling.
(2) *Chemicals*, in solution or powder.
(3) *Fumigation*, by gases or vapours.

Let us consider fumigation first. This is generally done by the production of sulphurous acid, or chlorine, the most common method being the burning of sulphur in a room after the doors and windows and various other openings have been sealed up. In all probability the sulphur fumes have no effect unless the atmosphere has first been moistened by a steam spray. This method has the disadvantage of spoiling any bright metal work which has not been covered by greasing—a prevention which should be taken before fumigation with chlorine or sulphur. A convenient quantity of sulphur to burn is 1 lb. to 1000 cubic feet. Although, as I have said, the burning of sulphur may have little or no direct effect in disinfecting living organic matter, I am not prepared to recommend the abolition of this time-honoured practice, for the indirect effect of the process is certainly great. The stench created by the sulphur is so disagreeable that people are compelled to keep open the door and window of a fumigated room for a long time, and so let in an abundant supply of fresh air, which is one of the most efficient of disinfectants.

A similar fumigation may be made by liberating chlorine gas from bleaching powder, but large quantities of chlorine are required to produce even a slight germicidal effect.

The best method of disinfecting the walls of a room which has recently been occupied by a sick person is the production of a disinfectant solution in the form of a fine spray. This can easily be done by the Equifex sprayer, a convenient apparatus which can easily be carried in the disinfecting van and worked by one man. The material generally used is formic aldehyde (formalin) vapour of the strength of about $\frac{1}{2}$ per cent.; or, if preferred, corrosive sublimate solution about 1 part in 1000. I have used formalin with good results.

Disinfection by chemicals in solution appears to be a very simple matter, and, provided the materials are used in suitable strength, no doubt is so. But not unfrequently the solutions used are too strong. You must remember that the desired effect is the destruction of living organisms, which consist of albuminous matter, and that the object of the chemical substance is to penetrate their interior. If, however, the solution of the disinfectant be very strong, the exterior of the germ becomes coagulated and resists any further soaking into the substance of the organism, so that practically no disinfection takes place, for the organism is not killed but only temporarily put out of action. On the other hand, you must not have the solution too weak. I find a solution of 5 per cent. carbolic acid, or of mercuric chloride (1 part in 1000) to be efficient disinfectants. This method of disinfection is convenient for such articles as sheets and blankets that have been soiled by infective matters. In all well-regulated hospitals such things are soaked for a few hours in some disinfectant solution before being sent to the laundry.

Disinfection by the sprinkling of powders is peculiarly applicable to surfaces that have been fouled by the

scattering of offensive organic matter. Apart from the deodorant qualities of such powders, their method of action consists in the evolution of some oxidising agent on the application of moisture. There remains for consideration, therefore, the method of disinfection by heat, the simplest application of which is boiling, which can be applied to most of those textiles usually cleansed by washing with water. But many articles, such as bed-hangings, and articles of clothing, curtains, cannot be boiled, and there remains for these the process of disinfection by hot air or steam.

Hot air.—Until some twelve or fifteen years ago, disinfection by steam was rarely done, the apparatus in use being the hot-air disinfector, the heat, as a rule, being supplied by a series of atmospheric gas burners. The objections to the hot-air apparatus are:—

(1) It is not an efficient disinfector, the temperature required to disinfect by hot air being much higher than that required in a steam disinfector.

(2) That this temperature is so high that most fabrics are destroyed by it.

(3) That air is a bad conductor of heat, consequently the time required to disinfect by no air is unduly great.

(4) Hot air does not possess the penetrating power of steam, so that although it may destroy organisms on the surface of an article, it cannot be relied on to destroy infection at any depth below the surface.

Hot air must never be employed to disinfect fabrics. Its use should be entirely restricted to the disinfection of articles such as leather goods, which are destroyed by the action of steam.

However, in modern disinfecting stations disinfection is carried on by means of steam. Now, in order to explain the action of a steam disinfector, I must remind you of two or three simple physical facts:—

(1) The boiling point of water, and consequently the temperature, varies with the pressure.

(2) The water in passing from its liquid form into steam absorbs a large amount of heat, which heat is again given out when steam is condensed into water.

(3) That under pressure steam may be heated considerably above the boiling point, viz.: 212 deg. Fah., when it is so called "superheated" steam.

(4) That steam under ordinary atmospheric pressure becomes condensed on coming into contact with a comparatively cold object. This is saturated steam.

(5) That superheated steam on coming into contact with a cold object may be reduced in temperature, but not sufficiently so to make it condense and give up its latent heat.

The behaviour of steam vapour and steam gas in reference to disinfection has been so well described by Mr. Defries, that I cannot do better than quote his description. He says, "It has been found to lie in the entirely different properties possessed by steam, both in its given killing power and the rapidity with which it will carry heat through itself and through persons' bodies, according as it is a gas or a vapour. I use these terms as approximately describing the two forms in which steam may exist."

A gas proper is, of course, the vapour of a liquid of which the boiling point is substantially below its actual temperature, and a vapour proper is the vapour of a liquid of which the boiling point is near such temperature. One obvious consequence of this fact is that a gas proper may be considerably cooled without condensing, while a vapour proper will condense on a very little cooling. When water becomes steam it is accordingly a vapour; but supposing that vapour is further heated, it will not condense until it has lost the whole of the heat so added, and in the meantime is found, in fact, to behave approximately like a gas proper.

The chief discrepancies in the results obtained by steam disinfection are due solely to the difference in the properties of steam vapour or saturated steam, and steam gas or superheated steam.

It will be seen, therefore, that with jacketed machines, which are worked with a higher pressure in the jacket than the chamber there is a danger of having the steam superheated, and in consequence delayed and inefficient disinfection.

There are other disinfectors, *e.g.*, Dr. Thresh's, which are worked with steam continuously passing through the chamber and therefore not under pressure at all. This machine consists of a disinfecting chamber surrounded by a boiler containing a solution of chloride of sodium conveyed through a ball cock from a service cistern. The steam which is formed at the top is conducted down from the cylinder and admitted to the disinfecting chamber at the bottom, being allowed continuously to escape. The object of the chloride of sodium is to obtain a higher temperature in the steam than would be got from pure water at ordinary atmospheric pressure.

VENTILATION.

The object of ventilation is to supply a proper amount of fresh air without causing a draught. Ventilation is *external* or *internal*.

External ventilation refers to the movement of air about houses, the manner in which such movement is interfered with by the proximity of buildings, also their height and the narrowness of streets.

Should external ventilation be defective, it is almost impossible to obtain the internal ventilation of a dwelling properly. Dwellings built back to back, as is commonly the case in Lancashire and Yorkshire, are exceedingly difficult to ventilate, owing to the impossibility of there being any through current of air.

The amount of fresh air which should be supplied to each person in a room continuously occupied is 3000 cubic feet per hour, so that if the room contains 1000 cubic feet, the atmosphere must be changed three times in the hour.

The composition of air—nitrogen, 79 per cent., oxygen, 20.96 per cent., and 4 volumes in 10,000 of carbonic acid, when the atmosphere of a room contains more than two volumes. In addition, as the result of being occupied, it becomes foul, and limit of permissible pollution is reached.

Many examples of apparatus for ventilating rooms were shown by means of lantern slides, the simplest, and the one generally recommended for ordinary sash window frames being the Hinckes-Bird ventilator.

QUESTIONS.

The following questions were asked by members of the audience, and answered by the lecturer from the platform:—

Q. Can typhoid excreta be safely buried in an ordinary cottage garden, and at what depth? How soon would it be safe to dig the garden?

A. Yes; about 2ft. In about two months.

Q. Is continued fever a mild form of typhoid?

A. No.

Q. How many years may typhoid germs continue to live (1) in soil saturated with discharges, (2) in an old disused rubble drain, (3) in a house imperfectly disinfected?

A. (1) For an indefinite period; (2) a long time; (3) several months.

Q. Is it not better to burn typhoid stools than to bury them?

A. Yes; if it can be done.

Q. Should the fumigation of rooms by sulphur not be

discontinued if not effective? What should take its place?

A. Yes; spraying the wall with formalin.

Q. Is it necessary to fumigate with sulphur after typhoid fever, and to disinfect bedding, &c.?

A. Some form of disinfection should be done after every case, but a formalin spray is better than sulphur. All soiled bedding, &c., should be disinfected by steam.

Q. Should rooms recently occupied by cases of puerperal fever or erysipelas be fumigated?

A. Either fumigated or sprayed with formalin.

Q. Would it be better to place typhoid excreta in special tubs provided by the Sanitary Authority than to put them down the water closet?

A. No; the sooner they are disposed of the better. If there be a privy midden instead of a w.c., the special tub should be used.

Q. Will sewer gas emanating from open grates in the street give diphtheria to children playing over them?

A. I think it may.

Q. What cubic space is recommended in hospitals and cottage houses?

A. In hospitals 1500 cubic feet. In cottage houses not less than 300 cubic feet per head.

Q. Do you consider back-to-back houses built in continuous rows with the sanitary conveniences next to the street unhealthy?

A. This style of house has the fault common to all houses built back to back, viz.: absence of through ventilation; otherwise the houses are as good as houses on the back-to-back system can be.

Q. Do the building bye-laws in Bradford prohibit back-to-back houses?

A. Yes.

Local Government Board Reports.

The Medical Officer's Annual Report.

Each year the report of the Chief Medical Officer of the Local Government Board increases in bulk, and proves that the work of the department is ever widening in its importance. The one recently issued, although bearing the signature of Dr. Power, has little to do with his work, for it deals with the closing period of Sir Richard Thorn Thorne's officership, which was so suddenly brought to a close in December of 1899. For this reason it appears to us that it lacks the stamp of individuality we have been so used to under the old *régime*, and which doubtless will be again present next year, when Dr. Power deals with events coming directly under his own supervision. The death of Dr. Thorn was not the only loss the department sustained, for in March, 1900, it lost Dr. Robert Cory, who for many years had been Director of the Board's Animal Vaccine Establishment.

It is still disappointing that the full vaccination statistics are over three years in arrears. If Dr. Power can devise means for expediting these important returns he will do a good public service, for really we cannot understand why they should be so much behind. We are told there were 927,518 children born in 1897, and of these 62·4 per cent. were returned as successfully vaccinated, 11·2 per cent. as having died unvaccinated, 0·3 per cent. as "insusceptible," and 3·4 per cent. as having had obtained "for them (under the Act of 1898) certificates of conscientious objection." This latter appears a little mysterious. Seeing that the Act was not passed until the autumn of 1898, and until that the "conscientious objector" was unknown, how could these certificates be granted? Accepting these figures as correct, however, there still remains 22·7 per cent. as "postponed, removed, or not to be traced," and this is the highest percentage yet recorded for England and Wales.

Other vaccination statistics refer to 1899. During this period 1461 vaccination districts were visited by Medical Inspectors, and out of 1461 vaccination officers, 1083 were recommended for grants. In the same period 499,281 capillary tubes of glycerinated calf lymph were issued in response to 47,097 applications from public officers. This number appears to have been far in excess of the expectations of the officers, for the provisional arrangements at the Animal Vaccine Establishment, at the Jenner Institute of Preventive Medicine, and at the National Vaccine Establishment, for the production, testing, preservation, and distribution of glycerinated calf lymph have, notwithstanding the extension of them referred to by Sir R. Thorne in his last report, proved inadequate. Accordingly, at the close of the year 1899-1900, negotiations were proceeding for setting up the several establishments on a wider and more satisfactory basis.

The administrative work of the Department was of a very extensive character. Quite a number of conferences between the officers and representatives of various Authorities were held in London. These were found to be most valuable, and proved the means of effecting considerable reductions in expenditure by the launching of ill-considered and impracticable schemes. Over sixty inquiries were held in regard to proposals as to hospital provision and accommodation; whilst several other districts were visited with reference to the provision of disinfectors, the erection of mortuaries, and the adaptation of bye-laws to local needs. Joint inquiries by Engineering and Medical Inspectors, with regard to schemes for sewage disposal and water supply, were held in more than a dozen places, whilst the scavenging arrangements of several others were brought under review.

Inspections were made with regard to the incidence of disease and to questions concerning local sanitary administration in various localities, namely: As to diphtheria at Aberdare by Dr. Thomson, and at Aldershot by Dr. Reece; as to enteric fever at Bilston and Coseley by Dr. Mair, at Chichester by Dr. Thomson, at Coleford by Dr. Fletcher, at Falmouth by Dr. Buchanan, at Heanor, Ilkeston, and parts of the Basford rural district by Dr. Wheaton, and at Shirebrook (Blackwell rural district) by Dr. Copeman; as to scarlet fever at Norman Cross by Dr. Bruce Low, and at Walmer by Dr. Sweeting; as to anomalous illness at South Witham (Grantham rural district) by Dr. Bruce Low; as to small-pox at Hull by Dr. Johnstone; as to suspected ship-borne plague at Liverpool, and as to alleged fatal plague at Suffolk by Dr. Bulstrode; as to sanitary circumstances and administration in the borough of Windsor by Dr. Bulstrode; in the urban district of Consett by Dr. Wheaton; in the urban district of Idle, and the rural districts of Braintree, Chelmsford, and Tendring by Dr. Fletcher; in the rural districts of Axminster, Biggleswade, and Chailey by Dr. Mivart; in the St. Dogmells rural district, and in the Dartford registration district (comprising Bexley, Erith, and Dartford urban districts, and Dartford rural district) by Dr. Sweeting; and as to the permanent constitution of the Manchester port sanitary district by Dr. Reece. Many of the reports on the above inquiries have already been referred to in our pages.

Following this general summary of the work of the Department, Dr. Porter proceeds to make special reference to some of the auxiliary scientific investigations carried out during the year, reports of which appear in the appendices. Some of these we may refer to in future issues.

National Health Society.

OFFICIAL TRANSACTIONS.

Examinations for the Diploma.—We have much pleasure in adding two names to our list of diplomées—Mrs. Fisher and Miss A. E. Biggs having successfully passed examinations on Nursing and Physiology (held recently by Mrs. Latter and D'Arcy Power, Esq., F.R.C.S., respectively), thereby completing the full course of training and examinations required for the diploma. Miss Madeleine Stampa has also successfully passed the examination on Nursing for the diploma.

ASSOCIATION OF NATIONAL HEALTH WORKERS.

On Thursday, May 9th, Dr. Robert Bowles lectured to the Association on "The Proper Management of the Physical Relations of the Tongue, Mouth, and Throat in Various States of Unconsciousness."

Dr. Bowles prefaced his lecture by shortly describing the elementary anatomy of these parts, indicating particularly that the tongue, being attached to the lower jaw by its mucous membrane and its muscles, has its relations with surrounding parts altered as the mouth is opened or closed. When the mouth is closed the horizontal portion or body of the jaw forms nearly a right angle with the spinal column, from which the symphysis is then at its greatest distance. When the mouth is opened by the dropping of the jaw, the symphysis describes the arc of a circle and approaches more nearly to the spine, where the posterior wall of the pharynx is attached. The tongue having its chief attachment to the symphysis, would consequently be drawn away from the pharynx in the former case, and allowed to rest in contact with it in the latter. These facts were made perfectly clear by two diagrams of a subject lying on its back on a table. In the first diagram the mouth was closed, in the second it was open. The dissection from which the drawings were taken was made on the body of a patient aged sixty, who died of cancer of another portion of the body, great care having been taken not to displace the parts more than was necessary to give a fair view of the base of the tongue and the epiglottis. When the mouth was open, and the subject on its back, the road to the larynx was completely obstructed, in consequence of the tongue resting in contact with the back of the pharynx; but the obstruction could be removed by hooking the base of the tongue forward. When the mouth was closed, the tongue was lifted from the pharynx, leaving ample breathing space. But even with the closed mouth, if the chin were much bent on the sternum, the base of the tongue was almost in contact with the back of the pharynx. From this dissection it would seem that the muscles of the tongue attaching it to the symphysis of the jaw are too short to admit of the base of the tongue reaching the back of the throat when the mouth is closed and the chin is well away from the breast bone. This dissection also suggested the necessity of caution being used in raising the head with pillows, for if the head be too much bent forward on the chest, the tongue may lie in dangerous proximity to the pharynx, even when the mouth is closed.

Several varieties of stertor may be recognised: (1) Nasal stertor, arising from approximation of the alæ nasi towards the septum by the in-going air, as in the act of sniffing. (2) Buccal stertor, due to vibrations of the lips, and puffings and flappings of the cheeks during inspiration or expiration. (3) Palatine stertor, arising from vibrations of the soft palate, whether the breath passes through the mouth or the nose. (4) Pharyngeal stertor, caused by the lolling back of the base of the tongue into near contact with the posterior wall of the pharynx. (5) Laryngeal stertor, referable to vibrations of the chordæ vocales. (6) Mucous stertor—a term which may be given to the bubbling of air through mucus or fluids in the trachea.

The dangers of the supine position in apoplexy are, (1) The falling back of the tongue, causing sudden and complete apnœa. This may occur in all cases of paralysis, whether from syncope, apoplexy, concussion of the brain, chloroform poisoning, suffocation from carbonic acid, or drowning. (2) Fluids or other foreign matters may be drawn into the larynx from the mouth and stomach. In convulsions of children there is often a large flow of saliva and secretion in the bronchial tubes. This becomes immediately churned into foam, and greatly impedes respiration. In the lateral position all this drains away, the breathing is freed, and recovery often commences immediately. In epilepsy the fit will often cease at once by removing the stertor by turning the patient on to his side; little mechanical contrivances are also necessary to oppose the spasms of the mouth, tongue, and fauces.

Drunken men put into cells overnight are occasionally found dead in the morning; while still unconscious they have been a little sick, as they are in the supine position, the vomit goes down the bronchial tubes and causes death by suffocation. Had they been placed in the lateral position, the vomit would have dribbled out of the mouth and the respiration have been left unimpeded. At an autopsy of a drunken man who had died from symptoms of suffocation, some of the contents of the stomach were found in the bronchial tubes.

In syncope, too, the lateral position is important, although the respiratory disturbances in this instance are secondary to heart failure. The tongue and its attached muscles become in effect paralysed, and therefore subject to the ordinary laws of gravitation. In syncope as in every other form of unconsciousness the air-ways must be jealously watched, and every possible obstacle to the free and easy entrance of air must be removed.

The Committee of the Royal Medical Chirurgical Society on Drowning came to the conclusion "that it was the entrance of fluid into the lungs, and the effects thereby produced, which was the cause of death in drowning." In drowning it is necessary to evacuate the water from the lungs and to provide for the introduction of fresh air by artificial respiration. Dr. Bowles contended that there is no known method equal to that of the Marshall Hall method.

The patient is placed in the prone position and the ribs firmly pressed so that the air in the lungs is squeezed out, and fluid can escape by the mouth. He is then turned on to his side, the ribs on the upper side expand and air drawn in. He is then placed on his chest and pressed upon as before. These semi-rotation movements, prone and lateral, are repeated fifteen times a minute; care must be taken that the patient is always turned on to the same side, preferably on the right. In 1861 a woman who had been taken out of the Serpentine, and treated by the hot bath at the receiving-house, was brought to St. George's Hospital about one hour afterwards. On admission "her breathing was fair, with loud rattling noise; her lips were livid, her pulse very good, her surface and extremities very cold; she was sensible, and able to speak." Warmth and appropriate measures were employed; but in half an hour the resident Medical Officer was summoned, and only arrived just in time to see her draw her last breath. The Marshall Hall method was immediately employed for half an hour without the slightest signs of recovery, but a large quantity of frothy fluid came from the mouth. At the post-mortem examination next day it was reported that "both lungs contained an immense quantity of frothy fluid; the bronchi were filled with fluid and injected." In this case the lungs were loaded

with and paralysed with water. Dr. Bowles argued that had the Marshall Hall method been used earlier it would have unloaded the lungs, and had the patient been placed on one side, on her arrival at the hospital, the upper lung would have cleared and acted quite sufficiently to sustain life. A lung containing frothy fluid does not clear immediately; the belts of foam must gradually coalesce and ooze slowly away, and to assist this nothing is more adapted than the Marshall Hall method.

Dr. Trollope, of St. Leonards-on-Sea, was called to a man who had been taken out of the sea. The man could speak a little, and vomited a quantity of water, but he rapidly became worse, insensibility came on, the breathing was slow and faint, and the pulse flickering. The Sylvester method was being used, and Dr. Trollope persisted in it for some few minutes. "Meanwhile," Dr. Trollope reports, "his respiration had ceased, beyond a slight mucous rattle in his wind-pipe, his heart's action could not be felt, jaw clenched and lips livid. . . . I then, finding these symptoms supervening in spite of the persistence in Dr. Sylvester's method, immediately had recourse to Dr. Marshall Hall's prone and postural, or 'ready' method, and was gratified to find fluid escape from the mouth each time the body was laid on the chest, and respiration gradually set up, commencing with long-drawn respirations, or rather gaspings, at intervals. I persevered in the prone and postural movements for three quarters of an hour, till respiration was thoroughly and satisfactorily established. The man then again vomited between a pint and a quart of water, and was afterwards able to swallow a few tablespoonfuls of tea and went on satisfactorily."

Dr. Bowles insisted then on the following principles: (1) That palatine, pharyngeal, and mucous stertor are the result of a mechanical condition—a condition which may always, and at once, be changed to the great relief of the patients, and sometimes to their permanent recovery. (2) That it is necessary to keep the patient on one side, that that side should not be changed, and that the paralysed side should be downwards. (3) That mucus and other fluids gravitate into and fill up the lower lung, and, therefore, that if the sides be reversed, the mucus will find its way into the opposite lung. (4) That the fluid, crossing from the large bronchi of one lung to those of the opposite, becomes churned into foam and causes dangerous obstruction to the respiration. (5) That the lung, by remaining inactive and filled with mucus for a long period, is not injured.

RATS AND THE SPREAD OF PLAGUE.

By D. S. Davies, M.D., Port Medical Officer of Health, Bristol.

Plague is a disease resembling, perhaps, typhus fever more than any other home disease in its method of spread from person to person by direct infection. It finds a suitable home, as does typhus, in localities whose insanitary condition connotes overcrowding, poverty, and stagnant air—conditions favourable to the intensification and transmission of the specific poison. If this were all, the method of medical inspection, isolation, and forward notification, would suffice to prevent its introduction, or at least to stamp it out before any serious spread occurred. But recent study of the disease has shown that plague is epizootic as well as epidemic; that is, it affects certain animals rats especially) as well as man, the two infections run together, and thus two epidemics have to be fought simultaneously, one above ground, the other below ground.

The disease has been observed in recent epidemics to spread slowly at first, but always with a tendency to get "set" in a place; sometimes, after apparent subsidence, to re-appear in a fresh quarter (due to migration of affected rats); and in India at any rate, to defy extinction over a series of years. Since its advent in India in 1896 it has caused over a quarter of a million deaths.

Rats have been demonstrated to have direct relation to the spread of plague by Yersin, Hankin, Cantlie, Simond, Weir, Surg. Col. Bainbridge, Dr. Doriga, Dr. Calmette and others. The following is a brief *résumé* of the chief facts:—

(1) Kitasato, Yersin, and others have found the specific bacillus of plague in the dead bodies of rats and mice, collected in houses in which cases of the disease subsequently broke out among the occupants, or in the streets of infected towns. They have also placed beyond question the great susceptibility of these rodents to the bacillus.

(2) In all the infected towns of India, manifest examples of contagion from rats to men have been observed. At Bombay, in certain establishments where the dead bodies of rats were found, it has been noticed that the persons who collected them alone contracted plague, although many other workpeople were engaged at the same place.

(3) The first cases of the disease have sometimes appeared in warehouses where wheat, cotton, seed, or other substances likely to attract rats were stored. At Kurachee, where the warehouses are situated in streets without dwelling-houses, the first sufferers were the caretakers.

(4) Well-constructed and well-maintained houses, *i.e.*, where rats cannot find harbour, nearly always remain free from plague. On the other hand is to be observed the permanence of infection in the houses of poor natives, notwithstanding the removal of the residents and furniture and the most rigid disinfection, because of re-infection from infected rodents.

(5) The epidemics at Bombay, Kurachee, and Karod were chiefly localised in quarters where the disease had broken out among rats. The spread of infection in other parts of these same towns was regularly preceded by the immigration and death of rats, and its diffusion always corresponded to the route of travel taken by these rodents in their migration.

(6) In healthy countries adjoining infected, the disease broke out amongst the inhabitants without the importation of a single human case, but was preceded by the immigration of rats from an infected place.

(7) In many countries and towns the development of the epidemic among the inhabitants followed a month after the importation of the first cases, or after the death of fugitives arriving from infected localities. During the interval the plague had been propagated by rats or mice.

(8) The mode of infection and propagation of plague on certain ships proved that the rats on board had been the vehicles of contagion.

(9) A well-demonstrated connection exists between the plague of man and that of rats or mice. The same specific agent (the Bacillus Pestis) is the cause of each. It is communicable from rat to man or man to rat. Either one or the other may be the vehicle of contagion from place to place. Although the transference of infection from a sick man to a healthy man does occasionally occur, the rat seems to be the chief and almost necessary agent of the epidemic diffusion of the plague.

The rat is far more dangerous than the mouse, because of its migratory instinct, which becomes an uncontrollable scourge, carrying contagion into distant quarters of a city or into adjacent countries.

NECESSARY MEASURES OF PRECAUTION.

(1) Owners of riverside warehouses and granaries should make systematic effort to exterminate rats. The mongoose is stated to have proved useful, or the pro-

fessional ratcatcher may be engaged. In some districts the rats have been inoculated with a coccobacillus (Danysz), which is fatal to them, but harmless to domestic animals. The action of this coccobacillus seems to be very uncertain, and its success to depend much upon the freshness of the culture, and partly upon the resistance of the particular species of rat. Special inquiry is being made as to its use.

(2) Shipowners should note the possibility of infected rats being introduced from infected ports, and adopt precautions when loading at such ports: (*a*) The mooring cables should be guarded by special conical collars. (*b*) Footbridges should be raised during the night. (*c*) Before loading, the absence of rats should be ensured, by trapping, poisoning, or fumigation; dead rats should be burnt.

(3) On arrival, the practical difficulty is to destroy the rats (which can only be reached by fumigation), without injuring the cargo. Ratcatchers are occasionally employed, and a price given for rats caught; discretion must be used not to encourage importation of rats to secure the reward.

We have found fumigation with sulphurous acid gas effectual in destroying the rats in the closed hold; but this can only be used after the cargo is cleared out.

Dr. Calmette, who was sent by the French Government to investigate the recent outbreak of plague in Portugal, has given an interesting account of his mission to the Société de Médicine Publique in Paris. He preaches a crusade against rats and mice as a measure of prevention. The French Government has already taken steps for the destruction of these rodents in ships arriving from plague-infected ports.

Dr. Calmette recommends that the discharge of cargo, especially grain and cotton, from places where plague exists, should be strictly forbidden till after the most rigorous inspection has been made. Bales and sacks should be opened and their contents emptied out and examined. If any dead rats are found, the whole must be destroyed without the ship being allowed to touch the quay. Further, a war of extermination should be declared against rats at home. A price should be put upon their heads, and he suggests that 50,000f. (£2000) be voted for the purpose. A capitation grant of 10 centimes, or 1d. per rat would ensure the destruction of half a millon rats.

In Denmark a campaign is already being carried on upon these lines. A price was put upon their heads, and an official report of the progress of the campaign in Copenhagen is issued weekly. In the first week the number was 6000, in the second 6616, in the third 6780. More recently the number has risen to 10,000. Other towns and communes have followed this example, and it is hoped that in no long time the rat will be extinct in Denmark.

In Russia a similar war has begun. At Odessa the following device to protect passage of rats over mooring ropes, has been used. The cable is run through a piece of iron pipe about a foot in length, and welded on the end of the pipe is a flange, a funnel which resembles the end of a trumpet with the wide end facing the ship. The iron pipe is stuffed with oakum to prevent slipping, and to prevent rats from passing through it; this is fixed on the ropes close to the ship.

THE ATTITUDE OF SHIP OWNERS AND SHIP MASTERS.

The measures necessary to rid a ship of rats are very simple, and a thorough fumigation with sulphur of the whole ship's interior when empty will practically suffice. The treatment of hold and cabin spaces must be simultaneous, as the vermin simply go from one to the other if the fumigation is partial, and so escape suffocation. In order to secure this thorough and simultaneous fumigation it is necessary that the ship should be in the hands of the Sanitary Authority, empty, for at least twenty-four hours. Many owners are unwilling to lay up a vessel even for this short time, and, in the absence of any evidence of infection, no compulsion can be applied.

The use of carbonic oxide, on which experiments are at present being made, would be yet more effective.

Until plague showed a tendency to its recent pandemic extension, cholera was the only exotic disease that seriously threatened Europe; as this is a distinctively human disease, the presence or absence of rats on ship-board was of slight moment.

But in the case of plague, which has been shown so clearly to be frequently rat-borne, the case is far otherwise; and communities have a perfect right to protect themselves against a danger which is recognised and preventable.

If shipowners can, at little inconvenience and small cost, rid their ships of rats, and by the exercise of due vigilance when loading at infected ports, do much to prevent infected vermin from gaining access to their ships, they should undoubtedly be under an obligation to do so; nor should they be privileged to introduce an unnecessary danger into home ports, or merit compassion because they suffer some inconvenience or loss when the presence of infection, which they should have prevented, is discovered.

It seems curious, too, that such definite precautions should be universally enforced against non-living infective material, such as clothes and bedding; whereas living infective material, endowed with locomotion and of migratory instincts, is allowed unrestricted importation.

It would result in a saving, not only to the health or lives of the crew, but also to the pockets of the merchants, if shipowners were compelled to take simple measures of precaution on the lines indicated; nothing can be more wastefully expensive than an actual outbreak of plague, and "prevention in advance," though less showy, is far more desirable than "stamping out," which involves the permitted introduction of disease.

Some of the difficulty in securing attention to the destruction of vermin on ship-board is no doubt due to the absence of official recognition of this special danger in the plague regulations for dealing with arrivals from infected ports; it is to be hoped that a new order will replace the obsolete regulations of 1896, bringing them up to date and strengthening the hands of Local Authorities, who, at present, are free to do as much or as little as they think fit.

A SPECIAL meeting of the Edinburgh and District Water Trust was held last week to consider a report by a sub-committee of the Works Committee in reference to the Provisional Order, 1901, of the Trust. Lord Provost Steel presided. The Trust met in private, and at the close of this sitting the reporters were admitted. The Lord Provost then formally moved the approval of the report which was in print. Mr. Archibald seconded, and the motion was agreed to. The Provisional Order provides for an extension of the time given by the Act of 1895 for the completion of the Talla works. The date for the completion is now fixed at 1908. The formation of the sinking fund is in like manner postponed for other three years; and power is taken to borrow an additional sum of £200,000. The report relates that the accountant of the Scottish office had raised some points as to the sinking fund contribution and as to the compulsory purchase of the perpetual annuities in favour of the old water company in the year 1870. A meeting ultimately took place at Dover House, when it was agreed that after five years from the completion of the Talla works a fund should be accumulated out of revenue at the rate of £2000 a year, to be increased to £4000 a year after ten years, towards the extinction of the water annuities above referred to.

CONCRETE SUBWAYS FOR UNDERGROUND PIPES.

At a meeting of the Society of Engineers held at the Royal United Service Institution, Whitehall, on Monday evening, June 3rd, 1901, Mr. Charles Mason, president, in the chair, a paper was read on "Concrete Subways for Undergound Pipes," by Mr. Arthur Taylor Allen, of Portslade.

In introducing the subject the author referred to the construction of the first subway in England for underground pipes which took place about the year 1860, in the City of London. This was followed a year or two later by one in the city of Nottingham. He noted the lack of progress there had been in the extension of these new arterial thoroughfares, for, beyond one being constructed at St. Helens in 1898, very little had been done in that direction to minimise the evil resulting from the continuous breaking up of roadways for access to the numerous pipes laid under every thoroughfare. He gave a long list of streets broken up in the course of one year for obtaining access to pipes. He also pointed out the danger and inconvenience likely to arise from roadways being laid over a number of gas pipes, which might soon prove to be of insufficient capacity or become defective, and over water mains that were laid years ago when the water supply was very limited.

The author referred to the sections of the various Acts in force empowering public companies to break up streets after due notice, causing the total or partial blocking of a thoroughfare, interfering with traffic, and operating temporarily to the prejudice of business houses, the owners having no claim for any loss sustained thereby. He then alluded to the increasing number of underground pipes and the possibility of the provisions of the Rivers Pollution Acts being more rigidly enforced, and in the near future throwing upon some Authorities the necessity of separate sewers for surface or storm water. The author then described the subways in London, Nottingham, and St. Helens. To relieve doubt as to the possibility of a severe frost affecting the water mains in the subways, he gave satisfactory thermometrical readings taken in the Albert-street subway, Nottingham.

Turning next to the utility of subways, the author stated that by their construction access could be readily obtained for the purpose of inspection, alteration, or addition to any of the pipes at present hidden and placed beyond inspection. He drew attention to the fact that after works of great magnitude had been undertaken in obtaining a pure water supply, to ensure the health and safety of the population, the pipes conveying the supply were hidden. Thus a defective joint or a burst might remain undiscovered for a length of time, as was the case some years ago when the first intimation of a leakage in the borough water mains was reported to him by the sewer men when repairing a sewer in close proximity to the mains.

An efficient system of detection and prevention of water pollution or waste would be provided for by subways, and the life of iron pipes would be considerably increased. Electric and telegraph wires need no longer run along poles and roof fixtures; they could be put under ground, thus rendering them less dangerous and more reliable and permanent. Having regard to economy of cost, capability of resistance, and rapidity of execution, the author suggested concrete as the most suitable material for such works, and referred to its practical value as exemplified by its extensive use in connection with works in general.

In dealing with subways for large cities and busy thoroughfares where foot passengers experienced difficulty in crossing the street in safety, the author recommended that, in conjunction with the subway, underground conveniences should form a part of the scheme. Entrances would be erected in the centre of the street, so arranged that an easy and ready access (although private) could be gained from the first landing. This might be regarded as a peculiar suggestion, but he alluded to the revenue it was possible for it to bring in, as much as from £200 to £2000 per annum having been cleared as profit for such accommodation.

With regard to subways for suburban districts the author considered all large subways should have lateral ways, about 3ft. wide by 4ft. 6in. high, for the purpose of access and conveyance of gas, water, and other pipes, and he advocated making use of every available space by a specially-designed iron bracket for the pipes. The author submitted a proposal for a subway under each footpath of all new streets to receive the water, gas, and other pipes, the subways to form part of the laying out of the new street. He considered it necessary that the gas and water mains should be in duplicate, the concrete wall nearest the house would be perforated with 2in. and 2½in. holes for the house services, thus obviating the construction and expense of lateral ways.

The sewer would be laid under the road with the usual manholes on the principle adopted in the present day, but with the addition of elongated eyes every 20ft., extending to each subway. The chamber (common to all house drainage) to be constructed in the bottom of the subway by and at the cost of the owner when requiring to connect with the sewer. This method, he contended, would ensure the surface of the road being kept free from interference.

The author gave the cost of some subways constructed in London as £15 per lineal yard, Nottingham £10 per lineal yard, and St. Helens £7 2s. 4d. per lineal yard. He pointed out, however, that the information was of but little practical value, and must be accepted with the greatest caution, it being impossible to make a useful comparison between the cost of construction at other places without a knowledge of the conditions of each case. Although the initial cost would prove heavy, he pointed out that there might be some compensation if the excavated materials proved suitable for the concrete work. The author considered that the cost of constructing subways should be borne by a loan for a period of fifty years, as the works come under the category of permanent works.

THE HOUSING OF THE POOR PROBLEM IN THE METROPOLIS.

By Henry Kenwood, M.B., &c., M.O.H., Borough of Stoke Newington.

It is now impossible for a poor family to obtain two or three rooms in London for the same sum which would have procured them a small house of their own a few years back, and thousands are literally starving themselves to pay extortionate rents.

The Local Authority can do much to promote the most satisfactory standard of sanitation and decency procurable in these highly-tenemented houses, but the standard is one which does not satisfy the least fastidious in scores of cases, and the Nemesis must inevitably follow of a progressive physical and moral deterioration of our London poor. When insanitary conditions, such as we can deal with, arise on these premises, one's natural impulse is not to spare the owner who is responsible for the circumstances which have led to such nuisances, but his general practice is to raise the rents, and make the tenants bear the costs of the improvements. I know of instances in Stoke Newington where as much as 7s. a week is paid for two small rooms, and the demand for such accommodation is so great even at that figure that the condition is imposed that no tenant with

children is received. It is not difficult to see what such a condition of tenure leads up to, and how necessary it is for those who can only afford two rooms to limit their families. This is one of the causes, in my opinion, of the falling birth-rate in our large centres of population. Extortionate rents for poor-class property have a great deal to answer for; they cause a high death-rate, a high infectious sickness-rate (for communicable disease must run through the whole of the susceptible members of the crowded family—if not of the whole house), physical and moral decadence, and the restriction of families. Now, the birth-rate is the chief asset of the State, and this housing question is not only one of local interest and concern, it is a grave national question affecting the health, morals, and vigour of our country. It is the most pressing and important subject which London has to deal with. The remedy of municipalising such property bristles with difficulties, but if it were practicable it would be the most beneficial public health measure conceivable.

Where private enterprise succeeds in dealing with the housing problem it generally only succeeds by tolerating conditions of tenancy which could not be countenanced by a Health Authority, and hence it might well be suppressed; but all municipal enterprise is handicapped by the payment of such exaggerated compensation or purchase money that an excessive expenditure of capital is entailed in any improvement scheme. If a house of £50 a year rental is made to bring in £100 by subdividing it into a series of small tenements in which people are allowed to house themselves like rabbits, then the compensation for expropriation should be estimated on the £50 annual valuation, and not on the £100. The community is now compelled to pay extravagantly for removing an evil for which the owners of slum property should properly be made responsible. Failing the enforcement of responsibility against the slum owner, the Local Authority should have the power to compel the sale of such property at the rateable value of the land and the materials. What is desirable is a reform in the existing law which will make it unprofitable to own hopelessly insanitary property. At present the cost incurred for "compensation" and construction leads to the substitution of dwellings which can only be let at a rental which is too high for the bulk of those evicted, who therefore increase the overcrowding in the adjacent slums.

Slums encourage drunkenness, and, on the other hand, a drunken, thriftless class will produce slums; and if drunkenness, vagrancy, and culpable pauperism could be effectually diminished, one result would be a largely-increased proportion of persons able to pay rent for improved and suitable dwellings.

It will be said that with lowered rents many will still continue to live huddled together and in filth, if they can thereby save something for dissipation. That may be conceded, but when the Sanitary Authority is in the position of being able to say that sufficient accommodation is procurable at such a reasonable rent that the people *can* live wholesomely, then it will be for the Sanitary Authority to see that they do so; and doubtless much of the present day dissipation among the poor is the direct outcome of their miserable homes.

Easy and cheap transport to the outskirts of our large towns would do away to a great extent with the need for the working classes to live close to their work; houses would be cheaper and the children would have a chance of growing up under natural and healthy conditions.

Hitherto the houses erected by public bodies in the metropolis with a view of re-housing some of the population displaced by an improvement scheme have been too expensive (from 2s. to 3s. 6d. per room). The breadwinners in such insanitary and dilapidated property are not as a rule skilled workmen, and most of them, even when the greatest care and economy are exercised, make little more than a bare living wage. To close the houses of such people because they are insanitary, and to offer them other houses at a much-increased rental, and often far removed from the scene of their daily work, is not seriously to attack the difficulty of improving the conditions of life of these people. To build houses that could not possibly be let under 6s. 6d. a week (as is generally the case), is doing nothing for a class of people who were formerly paying but 2s. 6d. The provision of the former class of houses may well be left to private enterprise. They will soon be tenanted by those who are in receipt of fairly good wages, and who are really not the class of people for whom it is so necessary to find improved accommodation. The whole question is, of course, beset with great and serious difficulty, and the present state of our legislation does little to assist in its solution. The problem which has to be solved in the near future by Local Authorities is how to provide healthy houses for poor people of a class that the speculative builder does not provide for.

It is very generally conceded that those in humble circumstances cannot afford to pay more for rent than one-sixth of the income earned. The class which stands most in need of municipal help in the direction of housing is the class which does not earn more than from 20s. to 25s. a week on an average, and these want accommodation at not more than 3s. 6d. to 4s. 6d. a week. Once the supply is equal to the demand, rent would resume a more rational ratio to the workman's wage, instead of the fourth or even third which it often represents at present. If they are going to meet this real want, Local Authorities must not dream of an "annual profit," but will have in many cases to subsidise such provision to some small extent out of the rates. The much desired extension of the period of repayment of loans for land purchase to a hundred years would do much to reduce the financial difficulties attending the great problem of the housing of the working classes.

The London County Council has hitherto done more in the direction of shifting the slum population than of re-housing it under its improvement schemes. The Boundary-street area originally accommodated 5719 persons, but only eleven of these found homes in the too expensive buildings erected upon the old site. The disease was, therefore, intensified, for neighbouring areas became still more overcrowded, and this will continue to be the case so long as the re-housing does not keep pace with displacement.

There must be in the metropolis at present some 500,000 persons ("the submerged tenth") who cannot afford to pay a sufficiently high rent to secure healthy homes. The number of paupers in the metropolis during last year was estimated at 125,000, and the common lodging-houses provide for some 30,000; the balance remaining is a formidable one. It is in the interest of the whole community that these people should be housed sanitarily; but the process is so costly that municipal enterprise is heavily handicapped. It must be cheapened. The rookery sweater has no claim to receive handsome compensation. If it were made unprofitable to own insanitary and degraded property, we should have less of it to menace the health of every community.

THE Water Committee of the Corporation of Liverpool met last week, when it was reported by the Engineer (Mr. Joseph Parry) that during the week ending 25th ult. the quantity of water supplied, within and without the compulsory limits, was 210,263,000 gallons, the daily average being 30,038,000 gallons. In the corresponding week of the previous year the quantity was 185,108,000 gallons, the daily average then being 26,444,000.

FOOD ADULTERATION IN WILTS.

Dr. Bernard Dyer, County Analyst for Wilts, in his report for the quarter ended March 31st last, says:—"I have analysed during the quarter 109 samples of various articles of food and drugs submitted to me by the Inspectors of the county, of which 89 samples were returned as genuine, while 20 were either adulterated or contained some ingredient to which I considered it my duty to call attention. Among the articles of food included in these 20 samples was a sample of margarine containing only about 8 per cent. of butter. This material was, I understand, sold as butter. Ten samples of butter, otherwise genuine, were found to contain boracic preservative, the quantity in two cases being as small as 0·1 per cent., or 1 part in 1000, in three cases about 0·2 per cent., in two cases about 0·25 per cent., in one case about 0·3 per cent., and in two cases about 0·4 per cent. In no case, therefore, was the quantity of boracic preservative so high as ½ per cent. A sample of margarine sold as such was also found to contain boracic preservative, but not more than about 0·25 per cent. We are still awaiting the decision of the Royal Commission appointed to consider the question of the legitimacy or regulation of the use of such preservatives as this in articles of food. A sample of marmalade was found to contain at least 20 per cent. of glucose syrup; a sample of mustard contained 10 per cent. of wheaten flour; a sample of mixed spice contained 4 per cent. of sand or earth—owing, presumably, to the neglect of cleaning the various spices used, some of which are imported in a very unclean condition; and a sample of whisky was found to be 7½ deg. below the lowest legal limit of strength. Among the samples of drugs submitted to me was a sample of quinine wine made up of a strength differing from that directed for the preparation described under this name in the British Pharmacopœia. Six samples of borax were submitted to me. Three of these contained traces of arsenic so small that I considered that the samples might be passed as genuine, having regard to the limitation of the doses of borax which would be given for internal consumption. Three samples, however, contained sufficient arsenic to make it desirable, in my opinion, that the attention of the vendors, and through them of the makers, should be called to the matter. Although even in these cases the quantity of arsenic was insufficient to be of medicinal or physiological consequence, it is well to recognise the desirability of a reasonably high standard of purity for drugs, and, in order that this may be brought about, it may sometimes properly fall within the duty of the public analyst to call attention to impurities which, while not sufficiently grave to cause the sellers of the articles to be classed as offenders under the Sale of Food and Drugs Act, are nevertheless evidences of lack of care in manufacture in a direction which, if exaggerated, might possibly lead to more serious contamination."

THE DECLINING BIRTH-RATE.

In the opinion of Dr. Denning, Medical Officer of Health to the Elland District Council, the steadily dwindling birth-rate is a serious matter. The district which comes under his special care has deteriorated in this respect to a startling extent. Fifteen years ago, in Elland, he says, the population could be estimated, generally correctly, by multiplying the number of inhabited houses by five. At the '91 census it was found to be exactly correct to multiply by four and a-half, according to the returns. Now, from what he has heard, the population will not be more than four times the number of inhabited houses. That is a very big drop indeed. The birth-rate in Elland is much less than in other towns. It is only about 17 per 1000, compared with 28 for the country as a whole. This is a tremendous difference, as he points out, and Elland's birth-rate has been going down for some time. Also, it has been below the average for several years. "The public," Dr. Denning remarks, "look upon this matter as a great joke, but it will soon be an important question. It is a serious thing for the birth-rate to be going down." His conviction is that the present generation of parents are not physically as fit as those who went before them. It used to be a question of the survival of the fittest, but that is not the case now. All the improvements in sanitation and in medical and surgical science have helped to preserve the weaklings, and these weaklings marry as soon as they can, and are more dependent upon someone else than strong people. That, he thinks, has something to do with the falling birth-rate. "You don't see the matronly women and the big powerful men that you used to see." As a country, Dr. Denning says, we seem to be going towards the state of France. A declining birth-rate is becoming general all over the land, and the lowest birth-rate ever recorded was last year's. This does not look very promising for a "dominant" race; it looks, to quote the Doctor's words again, "as if we are becoming a degenerate race." In his report of 1894 occurs this paragraph: "The birth-rate (22·82 then) continues steadily to decrease. In 1891 it was 27; in 1892, 26·3; in 1893, 25·38; and in 1894, the decrease is very marked. Whether this is a sign of deteriorating or advancing civilisation, I know not."

To sum up, Dr. Denning emphasises his remarks on "the survival of the fittest." With the advance of sanitary science, weaklings survive, who before would have died, and left stronger men, to be followed by a stronger race of children. South Africa has found out the weaklings, as the long lists of the disease-stricken show. Here in the busy North, where the air is befouled by belching chimneys, and where "the bleak and sombre grey reigns supreme, and the beautiful and variegated colours and shades which Nature provides for our enjoyment and enlivenment are defaced and rendered hideous by the greed and prejudices of the 'powers that be'" (as Dr. Denning so forcibly expresses himself), narrow-chested men and women are reared at the looms and in the factories. You have only, says the Doctor, to contrast the servant girl with her sister from the mill to see the difference. No doubt physical drill, such as the *Spectator* advocates, would benefit the rising generation, who so sadly need it to develop their bodies and make them strong.

Dr. Wynter Blyth, Medical Officer of Health for Marylebone, in his last monthly report has a reference to plague dangers. He says: "The health officers for the various ports continue to take the addresses of passengers arriving in this country from plague-infected ports, and to forward the same to the various districts to which the passengers are bound. A considerable number of such passengers are supposed to have arrived in Marylebone during the last five weeks, but in about 90 per cent. the addresses cannot be verified. It would thus appear that either the passenger knowingly gives a false address, or that circumstances occur altering his destination. If the Marylebone experience is any indication of what occurs generally, then the matter is one demanding legislation. It is obviously most important that in such a disease as plague all persons coming from an infected locality should be, for a week at all events, under the surveillance of the sanitary officers of any district in which they reside, and it should be incumbent on them to notify to the authorities their movements within the time of possible incubation. This would not interfere with personal liberty, nor should it cause annoyance or inconvenience."

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

AN ARCHITECT'S UTOPIA.

IT is only to be expected that the growing interest in the housing question should develop phases of original thought among the community of architects; but, unfortunately, originality of ideas does not always savour of the practical. Some of the suggestions set forth in a lecture delivered by Mr. Raymond Unwin before the Workmen's Housing Council serve to corroborate this view. We have every sympathy with the architect who objects to the so-called model dwelling, with its small and sunless rooms haunted by the ghosts of disease; but at the same time we are fully sensible of the manifold difficulties which Municipal Authorities have to face in providing even this much in the way of accommodation for the working classes. The poetry of health with its ideal stanzas, reminiscent of country cottages covered with honeysuckle and roses, is admirable in its way; but before this ideal is reached there are difficulties to be surmounted which mere theorising alone will never accomplish. When speedier modes of transit become general, and "land grabbing" is extinct, then, and then only, may we expect to see a move in the direction which the visionaries of Utopia would have us take. The suggestion that houses should be made to live in is one that no sane person would for a moment question, and we fail to see anything original in the contention that sunshine and fresh air are essential to the enjoyment of health and happiness. But how to bring these within easy reach of the City toiler is the real question at issue. With Mr. Unwin's suggestion that cottages should be built in quadrangles, and that there should be one common garden accessible to the tenants as a whole, we are decidedly at variance. The idea is opposed to every social characteristic of the Englishman whose house is his castle, and whose ambition it is to possess a piece of ground, however small, into which he can dig and delve at leisure, and where his children can romp and play uninterrupted by the conventional regulations of the public playground. We know too well these "garden spaces in common" with their officious custodians in uniform, and their stern injunctions to "keep off the grass;" and as lovers of freedom we hate and despise them. For the nonce they are essentially a City element, and we sincerely hope they will continue so. The lecturer pictured a place where the domestic cat would no longer have a reserve ground in which to lie in wait for sparrows—rough on the cat, and equally hard on the children, to whom this domestic pet is in many cases a real source of pleasure. But while objecting to Mr. Unwin's separate-garden-abolition scheme, we are heartily at one with him when he proposes to sacrifice ornate architecture in order to spend every possible halfpenny of the cost on a larger living-room. The miserable band-box which has to do duty as a living-room in the modern small house constitutes a disease-producing medium which should be summarily dealt with; but equally important, in our opinion, is the necessity for larger sleeping apartments. The abolition of passages, landings, sculleries, staircases, and recesses, advocated by Mr. Unwin, would be easy were houses built upon the bungalow principle; but here, again, the question of land value crops up. Some day, perhaps, when we are enabled to go whirling through space at the phenomenal rate of speed indicated by recent theoretical experiments, it will be possible to found colonies remote from cities, where the class of house dreamed of by Mr. Unwin will find an abiding place. We are all anxious for that day to arrive, and though we shall not be alive to see it, our children's children may, perhaps, enjoy the heritage. It is,

indeed, fortunate that the professional architect of to-day can find leisure and opportunity to put in a little overtime, as it were, for the benefit of posterity.

"Unhealthy Cannes."

Last week we referred to the very doubtful value of Nice as a resort for invalids. The Paris correspondent of the *Daily Mail* has also placed certain unpleasant facts about Cannes before the readers of that paper. He quotes from the letter of a local correspondent, in which it is asserted that "in spite of local subterfuges to conceal the fact, there is not the slightest doubt that there is an epidemic of typhoid fever in Cannes at the present moment. The wife of the Bishop of Gibraltar is seriously ill, and so is the organist of Christ Church. At the Château St. Michel, belonging to Lord Glenesk, there is a case of typhoid, and other cases are at the Villas Mariposa, Capodimonte, Valletta, Soligny, and Champfleuri. A servant has been removed from the Villa Barety to the hospital, and two domestics from the Villa du Lys are also patients there. A workman employed by Mr. George Russell has died from typhoid; a young man of twenty-eight years of age, son of a neighbour of mine, has succumbed to it; and I know another young Englishman who is down with it. Nearly everyone one meets knows of someone who has been attacked by the fever. In the town hospital there are twenty-eight cases, and one local doctor is said to have admitted that he has forty-eight cases under treatment." In another portion of the same letter we learn that "under the late mayor the consuls were furnished with a list of deaths and all complementary details, such as cause of death, &c. The civic authorities now refuse to give more than the bare list, and as the local papers do not publish complete lists one never knows how many die. I am told, indeed, that two registers are kept—one for public inspection and one which is authentic." It is only right that these facts should be known to the public. In the present day, when the tendency on the part of certain people is to cry up everything foreign and anti-British, it is well to remember that much of this clap-trap is written by those entirely ignorant of what they are writing about. It may be, in the eyes of some, fashionable to go to these places, and a bronzed face may be the outward sign that the "Sunny South" has been visited, but of what use is this if the system has been contaminated with the seeds of fever? With all its shortcomings the old Homeland is after all the safest and best place in the world.

A Strong Indictment.

There is likely to be a lively interchange between the Urban Council of Bishop Auckland and the Local Government Board, as the result of a recently-issued report on the sanitary condition of the district by Dr. S. W. Wheaton, one of the Medical Inspectors of the Board. In his report, of which we propose to give a summary in a future issue, Dr. Wheaton says some strong things about the administrative work of the town. He affirms that the "work of the District Council has always been fitful and irregular; even when their officers have drawn their attention to very pressing and dangerous nuisances they have dealt with them in a spasmodic way, apparently soon subsiding into their normal condition of apathy towards all sanitary work. As the result of long-continued inaction of the Authority, the district now finds itself threatened by a sudden and heavy expenditure for public and private improvements which can no longer be shelved, which expenditure would have been spread over the course of many preceding years if those responsible for local sanitary administration had only performed their duty." He goes on to say that "with respect to the prevalence of enteric fever in the town for so many years, the general sanitary condition of the district is so bad that it is difficult to fix upon any single unwholesome condition as playing a principal part in the spread of fever. On taking into consideration all the circumstances of the distribution and progress of enteric fever in the district, there is presumption that the disease has from time to time been introduced and distributed over the district by means of a contaminated water supply." Altogether this is a pretty strong indictment to bring against any public body, and we naturally wonder what can be said in defence. Pending the meeting of the Council the local papers have commented upon the report, and doubtless the line they take is an indication of that which will be adopted by the Council. The *North-Eastern Daily Gazette* boldly calls the Doctor's findings into question. It asserts that the visit upon which the report was based was "hurried," and that he only made a "hasty perambulation round the town in company with the Sanitary Inspector." And, further, that at the very period when Dr. Wheaton says things were so bad, the County Medical Officer reported a considerable improvement all round.

A Countercharge against the L.G.B.

We do not think, however, much will be gained by this style of recrimination, for at the best it can only be based upon hearsay. We think there is a much stronger case for complaint against the Local Government Board in another statement put forward by the same paper. We are asked to believe that the Urban Council itself has just cause for complaint against the central Board. It is said that when a Local Government Board inquiry was held in response to an application by the Urban Council to borrow a large sum of money to improve the water supply of the town the County Council objected, and the Local Government Board refused the loan. The result is that, despite this opposition, the work has been carried out; but the cost has had to be defrayed out of the current rates, which has imposed a heavy burden on the ratepayers—a burden which is likely to be increased. Then the Local Government Board refused to allow the sewerage to go into the river

a mile and a-half below the source of the water supply. Three or four years before the serious outbreak of enteric the Local Government Board approved of a large sewerage scheme, by which the effluent had to go into the river, the outfall works being near Binchester. Here, again, an insurmountable difficulty arose. The Ecclesiastical Commissioners in the land lease refused to give any guarantee against pitfalls. Under these circumstances the Council felt it would be folly and waste of money to proceed with the scheme, for after spending the ratepayers' money a pitfall, or a series of such, might render the sewage farm useless. As the same public body owns much of the land in that vicinity and district, the difficulties of the Council can easily be recognised. But for two months or more the work of preparing a scheme of sewerage for the southern end of the town has been in active preparation, and there is reason for believing that the plans and estimates were adopted a fortnight ago. "This much," says the *Gazette*, "can be honestly said for the Auckland Urban Council, they are honestly endeavouring to make the town a most healthy one in every respect, and in doing so they are hampered by the antagonism of a section of the County Council and the red-tapeism of the Local Government Board." It is quite likely, as we have already indicated, that more will be heard upon the matter. But it does seem to us that if there had been a little more energy displayed on the one part, and a little patience on the other, the present unpleasantness might have been avoided. In fact, is not this true of all disputes and quarrels?

Clifton as a Health Resort.

When your town has a good record, do not hesitate to make it known. And there are many parts of these isles which are worthy of greater notoriety than they at present possess. But there are very few districts where men can be found with sufficient enterprise to urge their Councils to take steps to bring their claims before the health and rest-seeking public. Even if the Bill some are proposing to introduce this session should become law, we believe that many will hesitate to spend so small a sum as a penny rate upon advertisements. These people are often quoting the proverb about "casting bread upon the waters," but they always think it must be somebody else's bread, not theirs. The Isle of Man and Blackpool owe much of their popularity and success to the attractive advertisements scattered throughout the country, and if others would follow suit much of the holiday traffic passing over to the Continent could be diverted to home channels. Where the municipality will not act, however, the example just set by Clifton might be followed. Here the "Municipal Association" has sent a circular letter to the principal medical men of the county pointing out the splendid health record which the place possesses. It is pointed out that the death-rate for the thirty-three towns was 20·2, in Clifton it was but 12·2. Taking the zymotic diseases, the test is even better. In the towns it is 2·81, in Clifton it is only 0·61. The infantile mortality is also very low—112·1 against 181—and is said to "confirm a popular opinion that it is specially suitable for children." The letter goes on to say that "Clifton is sometimes regarded as merely the residential suburb of a great manufacturing city, but our forefathers were wise in their generation when they made it a favourite health resort. The climate of Clifton is exempt from extreme variations of heat and cold. At the Sea Wall on Durdham Down a fine view of the Bristol Channel is obtained. It may therefore be claimed that the air of Clifton combines the qualities obtained at an inland watering place with those of the air at a seaside resort — an up-channel breeze coming directly from the Atlantic Ocean. The breezy open Downs, 442 acres in extent and 300ft. above the sea level, and the extensive wooded slopes on the Somersetshire side of the river, give to it all the advantages to be gained by restful, quiet, and pure air, while the magnificent scenery of the Avon gorge and the surrounding country is a never failing source of interest." From personal knowledge we can confirm many of these claims.

The Pinewood Sanatorium, Wokingham.

The *Times* has an interesting description of the new consumptive sanatorium at Wokingham, to be known as Pinewood Sanatorium, which is being erected under the auspices of the London Open-air Sanatorium Association, and is now approaching completion. The chief obstacle with most similar institutions is that, being private ventures, the charges for admission place their benefits beyond the reaches of a very large class of sufferers. There are others, on the other hand, which are designed more particularly for the poor. The establishment at Wokingham aims at the mean, and is devised to meet the needs of that large class of the people who are neither very rich no very poor. After the Marlborough House meeting, at which the work of the National Association for the Prevention of Consumption was fairly launched before the public, the London partners of Messrs. Wernher, Beit, and Co. agreed to find £20,000 to build and equip this sanatorium, on the terms that after payment of all working expenses they should receive 2½ per cent. for their money; should the payments of the patients—which have been provisionally fixed at three guineas a head per week—yield any surplus profit after payment of this interest, it is to be devoted to the objects of the sanatorium. The buildings will consist of a central administrative block, with two blocks on each side for the accommodation of patients, all facing almost due south, so as to secure the maximum of sunshine. The two pairs of patients' blocks are connected each with a continuous passage running the entire length of the north side, the bedrooms, of which there are sixty-four in all, being arranged on the south side. The bedrooms are constructed with a cubic capacity of about 1000 cubic feet each, and the south side of the rooms is practically all window, two case-

ments and a fanlight affording the maximum of light and air. A feature of the buildings is that the joiner work is of the simplest possible character, with a complete absence of mouldings or angles, so as to avoid accumulations of dust. The dining-room is placed behind the administrative block, but unconnected with either it or the patients' blocks, so that to reach it from the other buildings it is necessary to pass into the open air. The other accommodation is all of the most complete description. Special mention must be made of the laundry, in which provision is made for disinfecting soiled linen by superheated steam before it is washed. There is an excellent water supply, and the septic-tank system is employed for the disposal of the sewage. It only remains to add that the site of the sanatorium is 300ft. above sea level, the grounds extend to 85 acres, and they are surrounded in every direction by pine-woods, from which the name of the establishment is derived. So judicious a combination of the resources of science and nature will, it is hoped, achieve great good in the interests of suffering humanity.

The Part Played by Disease in History.

A highly original and interesting view of the function of disease in shaping the history of the world, and particularly of civilisation, is developed in a lecture delivered in Edinburgh University by Dr. S. Archdall Reid. He claims that zymotic diseases have produced evolution of such vast political and biological importance, that the effects of all wars and diplomacy fall into insignificance beside them. Malaria, for example, where it is virulent, acts as an absolute check to colonisation; and the inhabitants of malarial regions must probably be considered to have undergone a gradual and painful process of evolution, in the course of which they paid toll in millions of lives, before they could dwell secure in their fever-haunted fastnesses. But now they cannot be displaced by incoming hordes. Similarly, Dr. Reid points out, our civilisation has been conditioned by our power of resisting certain infectious diseases—a power which has been acquired by a long process of evolution. The races of the New World are suffering extinction in large measure through the introduction of Old-World diseases. With regard to our own Anglo-Saxon race, Dr. Reid shows that they now occupy so large and fertile a portion of the earth's surface, that their world predominance in the future is assured. They may be beaten in war, they may break up into separate governments, but disease could not now exterminate them, and their increasing numbers must give them the ultimate victory. Of the momentous march of disease, which has founded great empires, and for ever changed the political face of the world, historians tell us nothing, while the theme has also been totally neglected by biologists and anthropologists. When the New World was discovered four hundred years ago, a new factor in empire building came into play. Unnoticed by historians, it has given to one vast empire, the Anglo-Saxon—an empire founded by a little people—a stability so great that it will probably endure as long as the human race inhabits the earth. This new light in which to regard history is certainly original, and the application of the method to various climes and peoples, in different periods, may be readily conceived to yield some interesting results.

The Extermination of Rats.

Rats have long been inseparably associated with the plague. Their connection with the outbreak in Glasgow was never conclusively proved, but in India, in Egypt, and latterly in Capetown, they have been, beyond a doubt, largely instrumental in disseminating the disease. Whenever a plague scare arises, one of the first measures proposed is the destruction of rats, but the thing, in a thoroughly complete and effective fashion, is more easily proposed than done. More particularly is it difficult on board ship, and yet it is by means of ships that these insufferable rodents carry the disease germs from port to port. A special interest, therefore, attaches to the recent experiments at the London Docks for the extermination of rats by means of sulphur dioxide gas. This gas seems to have the property of attracting the rats from their holes, and as soon as they breathe the fumes they become suffocated; at the same time it has no injurious effect upon the decorations of the saloon. The experiments were conducted on board the steamship Gourkha, and were highly successful, several hundred rats being destroyed in the space of a few minutes. Among those who witnessed the experiments on the Gourkha was the Chairman of the Cape Chamber of Commerce, and he is said to have been so much impressed with the efficacy of the new method, that he has resolved to recommend its adoption to the Harbour Board at Cape Town, with the view of applying it to all vessels coming from plague-infected parts. We understand that the system has for some time been in operation in America, and the officials of the Board of Health in London are now investigating it with a view to its more general adoption.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

The Municipal Engineers' meeting which was held at Chichester on Saturday last was not so well attended as these meetings usually are. This was doubtless due in considerable measure to the fact that Mr. Saunders, the Borough Surveyor, was not enabled to show any new feature or any new work in municipal engineering of general interest. His paper was a record of work well done, which is something more than can be said of most cathedral cities, which are, as a rule, both dreamy and sleepy. The gospel of sanitation was late in being adopted at Chichester, for until 1894 no drainage system existed, and the sewage was turned into soaking cesspools in gravel and chalk, such cesspools not infrequently being directly under the rooms of dwelling-houses with shallow wells for domestic water supply closely adjacent. As a consequence outbreaks of enteric fever were frequent—as any novitiate in sanitation would

expect to be the case. But the proposal to sewer the town provoked bitter opposition, and divided it into two camps—"drainers" and "anti-drainers"—and a lively campaign ensued.

It cannot, however, be said that Chichester folks were much worse than those in scores of other towns, for ignorance and vested interests prevail everywhere, and these factors are always in prominent evidence when measures for improving the sanitary condition and affecting the district rates of a town are projected. Ignorance, however, does not belong, like riches, to a particular class, and an interesting illustration of it was narrated by Mr. Saunders, for, he writes, "in the 'drainage campaign' one of the medical practitioners strongly advocated, in lieu of drainage, a scheme to sink cesspools opposite each house in the centre of the streets, and have the same periodically emptied." That medical practitioner, it appears to us, should be mummified and preserved in a glass case in the local museum as a curio.

The Chichester Corporation cannot be congratulated on the system of sewage disposal which they have adopted, which is costly, inefficient, and dirty, and they would be well advised to discard it as soon as practicable, to the benefit of the district rates. The annual cost of maintenance of the farm, excluding interest and repayment of capital, is £1040 for a population of 10,000, or at the rate of £7 per million gallons of sewage treated, and the purification even at this cost is very incomplete, as the effluent is discharged into the harbour. The Corporation should make themselves acquainted with more modern systems, and a little money spent on a deputation consisting of members of the Sewage Works Committee to see what is being done in regard to treating sewage in other towns would be a good investment for the ratepayers.

But Chichester—notwithstanding its sluggishness in municipal affairs—can give points to another Corporation which is now much in evidence for its antiquated methods of government, viz., Gravesend. This Corporation is one of those effete invertebrate bodies which do not own the gasworks nor the waterworks, and what is more, they do not even appear to possess a sewerage system nor sewage works, although the town has a population of 25,000. The Gravesend Corporation, who have just been pilloried before the Local Government Board for their sins of omission, gravely explained that "Gravesend was just like most other places except that it had cesspools instead of sewers," but the Gravesend cesspool was—according to the estimation of this august body—a paragon of perfection, for it was a perfect septic tank, absolutely out of sight, and, being out of mind, "it was admirable." Moreover, the system of emptying the cesspools by hose pipes and pumping the sewage through the houses to cesspool vans in the public streets was so perfect that there was absolutely no nuisance, and the Gravesend system, the Local Government Board was told, was held in admiration by members of other Councils! One would think so, too, and the system of municipal administration should be a source of admiration also for its antediluvianism. The Gravesend Councillors must be classed as modern Rip Van Winkles, but it is time they awoke, even if it be necessary for the Local Government Board to undertake the task.

Some time ago I drew attention in this column to the growing dissatisfaction to members of local authorities and also to a considerable number of Medical Officers of Health with the results of isolation hospitals, and that instead of such buildings serving to reduce the incidence of infectious disease in districts where they had been introduced, such diseases had prevailed to a greater extent subsequent than prior to their introduction. Since I last wrote—now twelve months ago — the case against infectious hospitals has grown stronger, and the spread of dissatisfaction at the failure of the system has extended greatly, as may be seen from a perusal of the columns of medical journals.

More than this, the ratepayer has just cause to grumble, for the cost of maintenance of such hospitals grows at an alarming rate, and in some districts it has caused an addition to the rates of as much as 8d. in the £. This might possibly be borne without much murmuring if adequate results could be shown, but when it is seen that, coincident with the extravagant cost, infectious disease is not reduced, but has grown more prevalent, "the worm" not unreasonably "turns." It is no use blinking the fact that the system is faulty somewhere, and the sooner this is generally recognised and 'the leek' eaten the better. The time may not yet have arrived when a Royal Commission should be appointed to inquire into the methods of infectious disease isolation as now practised, but I venture to predict that this will be inevitable within the next two or three years, and those who can help it forward will be doing good service.

Reference was made in these notes recently to the annual election of members for the Council of the Municipal and County Engineers' Association. Since my previous notes were written the ballot list has been in the hands of the members and the voting has taken place, with results which will not be declared until the annual meeting in June at Leicester. It is encouraging to observe that more interest has been taken in the election this year than has been the case in the past, and it is evident that members realise that the management of the Association is unsatisfactory, and that the task of removing the inertia must proceed from themselves and not from the Council, who are either unwilling or not desirous of grappling with the problem.

One of the evidences of this increased activity was the circularising of Surveyors to Rural District Councils to record their votes for a rural surveyor whose name was given on the circular, which, however, was not signed by the individual who issued it, and it may, as one member has pointed out to me, have been sent out by the candidate himself—a proceeding which is in violation of the rules of the Association, which prohibit any member canvassing for votes for the office of member of the Council.

But one fails to see the *raison d'être* of the complaint. Sectional representation has nothing to recommend it, and while rural surveyors are justly entitled to vote for whom they choose, is there any specific ground of complaint that their interests have been overlooked? I have taken the trouble to make inquiries into the matter in different quarters, and can find no evidence to support this. Nor can it be justly said that rural surveyors, as a class, are disparaged. Only those, I am assured, advance such a statement whose personal idiosyncrasies have led their fellows to value them possibly in a different light from that seen by themselves.

It is singular that rural surveyors should have adopted such a naïve way of endeavouring to secure the election of one of their number. I venture to think that if they sent in the name of a candidate to the secretary of the Association before April 20th, as any member is empowered to do by the rules of the Association, such name would have appeared on the list. Why this was not done seems inexplicable. I am confident that by following the usual course their laudable desire would have been better recognised than by proceeding in the irregular manner which has been adopted.

Senex.

CORRESPONDENCE.

(*To the Editor of* The Sanitary Record.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

SUCCESSFUL SEWAGE TREATMENT.

Sir,—On page 338 of your valuable journal of issue of April 18th appears an extract from the report of Dr. George Bury Wray (not Bray, as printed), Medical Officer of Health to the Basford Rural District Council, on the successful treatment of sewage at Kimberley, near Nottingham. As I personally superintended the conversion of these works to that of the Cosham system, I have perused the article with more than ordinary interest. Having acted as clerk of works over many sewage works, ten of which have been on the Cosham system, I find that where chemicals are used much better results are obtained by this system than others, and that with one-sixth part of the chemical recommended by the manufacturers. This in itself is a great consideration; but according to Dr. Wray, the tanks have been working for upwards of a year without the use of chemicals. There are two things that we may learn from this report. (1) That it is unnecessary to incur the expense of covering tanks with arches to exclude the air and light, as the same results seem to be obtainable with open tanks; (2) that we may estimate with some amount of certainty the quantity of sludge we have to deal with in the bacterial system.

On referring to an old note-book, I find that the sizes of the tanks referred to (six in number) are, No. 1 tank, 30ft. by 30ft. by 7ft. deep; No. 5 tank, 30ft. by 15ft. by 7ft. deep from floor to overflow, the capacity of the two being 350 cubic yards. This is the quantity of sludge the Doctor assures us accumulated in the first two tanks in the space of eleven months. The sewage consists of the waste water from two large breweries, several slaughter-houses, mineral water manufactories, and from about 5000 inhabitants; the sewage often comes down to the outfall very hot indeed, with a fair amount of spent hops, the tank capacity being only about seven to eight days' dry-weather flow, according to the capacity defined on the bacterial lines; their work is heavily handicapped. It would be interesting to know whether there are any more Authorities who have adopted this class of tank for the treatment of sewage by the bacterial principle, and if so, with what results.—Yours faithfully, W. Cowper.

Thame, Oxon, June 3rd.

FACTORY *v.* HOME-MADE CLOTHING.

Sir,—I was much struck with the force of Mr. Robinson's letter on this subject in last week's issue of The Sanitary Record, and would like to add that some of the large tailoring factories, or "workshops," as they are known in the Factory Acts, are almost, if not quite, as bad as anything to be found in domestic workrooms.

I have in mind one large tailoring factory, or "workshop," in a city in the North run up by a jerry builder on part of a disused burial ground, which was prepared—when I was a youth—for building on, by having some of the corpses removed so that the wall footings might be put in; the remaining corpses being left undisturbed. The soil-pipe from a series of water-closets passed through the kitchen within a foot of the washing-up sink; indeed, food, and plates, and dishes were frequently piled against it. Of course, there was oftentimes a bad smell—it was almost a permanent condition in the kitchen. There was no ventilation, and in the season I have frequently known the various workrooms overcrowded to an extent of over 70 per cent. I won't attempt to describe the elementary efforts made by the over-worked staff to give the place an appearance of cleanliness; it will be sufficiently understood when I say that the first thing I did on going home after visiting this place was to strip and take a bath and then walk carefully into an adjoining room and put on another complete suit of under and over clothing, leaving that which I had left off to be washed with a disinfectant.

The appearance of vermin upon the goods manufactured in this place was of such frequency that it called forth no surprise whatever—it was either shaken off or whisked off, accompanied by a remark referring to the "Norfolk Howards" or the "Scots Greys."

Don't imagine I have drawn an exaggerated picture of the only place of its kind, for there are many others more or less like it. Their cleanness and sanitary character are oftenest only skin deep. Don't think, either, that I have selected a place belonging to "Jew sweaters," as I have not. The owners are a well-known firm of highly respectable traders, who do only a retail trade, and so far as I know, they are no worse than a great many others.

My knowledge of the conditions under which clothing is made have led me never to buy garments from any maker except I knew who he employed and the manner in which the work was executed, and to steadily refuse all inducements to purchase so-called "cheap" things.

Even if the factory or workshop were sanitarily perfect, it must be remembered that the workers are mostly drawn from the very poor, badly trained, almost uneducated portion of the community, and their condition and that of the homes they live in reduce considerably the chances of purchasers obtaining clean, vermin-free, and disease-free clothing.—Yours faithfully,

Manchester, June 1st. M. Finlay.

"SCHOOL SLATES AND DIPHTHERIA."

Sir,—With reference to a note under the above heading in your journal of May 30th, 1901. In 1896 I published in the *Lancet* a note on "The Slate and Slate Pencil as a Means of Transmission of the Infective Material of Diphtheria and other Diseases amongst School Children." At that time I was investigating a serious outbreak and epidemic of diphtheria in the borough of Maidstone.

I then advised the School and Sanitary Authorities to insist upon the placing of all slates and slate pencils in the several school coppers or boilers, which contained a solution of sodium carbonate (common washing soda) in water, and boiling them for half an hour and then allowing them to drain and dry spontaneously. This, together with the boiling of the school dusters, was systematically adopted. A duster was wrung out in a suitable non-poisonous disinfectant (such as a solution of the bisulphite of lime in water), and was used to erase the writing on the slates during school hours, and the desks and forms were also washed with a similar disinfectant.

The risk of the transmission of infectious diseases by means of the slate is thus reduced to a minimum, and personally my experience inclines me to believe that a piece of slate (unframed) together with a slate pencil, are the cheapest and the most suitable materials for the use of school children, whilst the objections to the use of paper and lead pencils are many, and, even when burning after use is adopted, most difficult to carry out.

Lead pencils are often placed by the children in their mouths and passed from one to another, both within the school and outside. All paper must be carefully and systematically collected and burnt, and not carried out of the school by the scholars. Prevent this. Its retention in the form (of permanent records of the work done by the pupils) as copy-books is open to many difficulties f infectious disease break out in school, as

the disinfection of books and papers, &c., in steam steriliser is both inconvenient and expensive.

My experience of the disinfection of both books and paper (both at home and in India) is that apart from the great non-conductivity to heat of paper, the inconvenience and delay caused to the school during the disinfection, and the subsequent requests for compensation if the least injury is done to the glue and the covers, &c., of school books and the several other articles which must be disinfected when infectious disease arises in a school, is such as to disencourage its extension to exercise books or writing paper.

On a small scale it may be practicable, but on a larger scale I much prefer the slate and slate pencil, which can be dealt with satisfactorily every day if necessary, and checked too.—Yours faithfully,

P. Targett Adams,
The Medical Dept. of the G.P.O.,
2, Fitchett's-court, Noble-street, E.C.

Public Works.

SEWERAGE.

A proposed sewerage scheme for Haworth is estimated to necessitate a loan of £20,000.

At a recent meeting of the Blaby Board of Guardians the Clerk was authorised to make application to the Public Works Loan Board for a further loan of £1411 for sewerage works.

The Mutford District Council has decided to apply to the Local Government Board for sanction to a further loan of £750 for the purpose of completing the Kessingland drainage scheme, making a total of £3850.

The Nuneaton and Chilvers Coton Urban District Council has given the orders for "Meldrum Simplex" Destructor to be erected at its sewage works to supply all power for pumping, &c. A similar plant has been working at Hereford sewage works for four years, resulting in a saving of £400 to £500 per annum.

Last Thursday afternoon there was a large gathering present at the invitation of the Portslade and Southwick Outfall Sewerage Board, to witness the formal opening of the outfall sewer for the drainage of the district. The Chairman (Mr. W. Mews) made a few interesting introductory remarks on the object of the gathering. In a few years, he said, it would be almost past belief that two parishes such as Portslade and Southwick, with a population of some 9000, should have been without any means of disposing of their sewage save by evil-smelling ditches and cesspools. The carrying out of the drainage scheme, he said, had been a matter of eight or nine years' work, during which time they had had many difficulties to contend with. Enumerating these, he mentioned that the Shoreham Harbour Trustees had declined to allow any drainage whatever to enter either arm of the harbour. Then the Board of Trade had raised objections to plans on the ground that the navigation would be interfered with. Their friends at Southwick, too, and also the Authorities at Brighton and Hove, were zealous that no sewage should find its way on the beach. The contract for the present work was entered into two years ago. The land portion of the work had been completed in 1899, and the whole of the time since had been taken up by getting the syphon and the outfall out to sea. He went on to speak of the efficiency of the syphon and outfall, and then gave a word of praise to the clerk of the works (Mr. Hockley) for the admirable manner in which he had carried out his work.

The Christchurch Town Council proposes to drain the borough at a cost of £22,000.

The Wetherby District Council has appointed Mr. E. J. Silcock, M. Inst. C.E., of Leeds, to advise it with reference to a joint drainage scheme for Bramham, Clifford, and Thorparch.

A Local Government Board inquiry has been held at Barrow-on-Soar with respect to an application of the Rural District Council to borrow £9250, the estimated cost of sewerage and a sewage disposal scheme.

At a recent meeting of the Barry District Council it was decided to call the attention of the Sanitary Committee of the Glamorgan County Council to the want of a proper system of drainage at Dinas Powis. It was stated that there was a grave suspicion that the water supply of Barry was being adversely affected.

A Local Government Board inquiry has been held by Mr. Tullock, with reference to the application of the Milton Rural District Council for sanction to borrow £800 for works of sewerage and sewage disposal at Newington. It is proposed to install the septic tank process of sewage disposal in the parish in order to deal with the sewage question.

On the Army Estimates, Vote 10, for works and buildings, a discussion of much interest recently took place on the expenditure incurred on sanitary work in connection with Aldershot and Salisbury Plain. The sewage farm at Aldershot, it appeared in the course of the debate, only accounted for an additional £1500 of the expenditure, and this was due to the increase in the size of the farm caused by the greater number of troops. Salisbury Plain, with the new barracks erected near Ludgershall, absorbed most of the additional money. The site of the new barracks was described as insanitary, and with a very defective water supply. Mr. C. Hobhouse dwelt on these points as likely to be injurious to the county of Wilts, which had taken great interest in sanitary work. Lord Stanley, in reply, assured the Committee that the sanitary needs of the new buildings and camps would be carefully considered, and the vote was carried by a majority of 67.

A letter from the Local Government Board was read at a recent meeting of the Tendring District Council in reply to the Council's application for sanction to borrow £2500 for the purpose of a scheme of sewerage for the parish of Thorpe, stating that it appeared from the plan that the effluent from the filters was proposed to be discharged directly into the ditch, and no provision was made for the laying out of any part of the land as an irrigation area. It would be contrary to their practice to entertain a scheme of sewage disposal of this character unless satisfactory provision was made for the purification of the effluent on a suitable area of land. The plans were returned for reconsideration in this respect. Mr. Golds observed that it was usual to allow one acre for every 200 population. Regard would also have to be made to the mixture of the subsoil. The subsoil in this case was London clay, and therefore not suitable for irrigation purposes. The matter was referred to the Surveyor to report upon it at the next meeting.

WATER.

At a recent meeting of Berwick Town Council, sitting as the Sanitary Authority, it was agreed to adopt a scheme proposed by the Water Committee, whereby water consumed for other than domestic purposes will be charged for either by meter or by agreement. The basis of the charge is to be 1s. per 1000 gallons, subject to a deduction for quantities exceeding 100,000 gallons yearly. It was estimated that the scheme would effect a saving of 2d. per £1 on the rates.

At a meeting of the Castle Douglas Town Council, a report by Mr. R. F. Miller, engineer, Glasgow, regarding a new water scheme, costing £930, was adopted. The money is to be borrowed, the re-payments extending over thirty years.

The Heywood and Middleton Water Board Bill came before Lord Morley's Committee of the House of Lords recently as an unopposed measure. The promoters seek authority to spend £175,000 on increasing the capacity of the waterworks. The Bill was ordered to be reported for the third reading.

At a meeting of the Water Committee of the Crieff Town Council the estimates for the cutting of the pipe track and the laying of the pipes were submitted. The successful offerer was Mr. John Pollok, contractor, Glasgow, the sum being about £1150. It is understood that the contractor will commence operations before the end of the month.

At a meeting of Sculcoates Rural District Council last week, Colonel Wellsted reported that 3000 yards of mains would be required to connect the water supply of Hull with Preston, and with a 5in. pipe that would cost £1500. Mr. Bancroft, Corporation Waterworks Engineer, suggested that an 8in. pipe should be laid. If this were done the Preston people would have to pay a difference of 5s. a yard. The cost of this scheme, and that of connecting Salt End-lane with Preston, will be reported to a future meeting of the Council.

A special meeting of the Brynmawr District Council was held recently for the purpose of further considering the proposed water scheme. The plans for the improvement of the water supply at a cost not exceeding £8000 were approved. The scheme provides for a new system of distribution mains, and the placing of service pipes in all houses; the capacity of the filters will be doubled, and with the balance left after the above works have been carried out, it is proposed to increase the capacity of the reservoir from 8½ to 16 millions of gallons.

A special meeting of the Aberdeen Town Council was held last week for the purpose of considering a report from the Water Committee. This Committee reported that it had considered the question of the appointment of an engineer in connection with the city water supply, and unanimously recommended that the services of Mr. Charles Hawksley, M. Inst. C.E., Westminster, should be engaged, with the view of obtaining a report as to the best source for a new or additional water supply, with an estimate of the cost. The charge for Mr. Hawksley's inspection, survey, and report was stated to be twelve guineas a day. This report was adopted.

The Board of Trade has granted a Provisional Order to the Dearne Valley Waterworks Company authorising them to raise £23,000 additional ordinary capital. Of this sum £3000 is to be issued "to the holders of the existing share capital 'A,' rateably according to their respective holdings in respect of profits which have been expended upon extensions and improvements of the undertaking." The remaining £20,000 is to be raised by shares of £10 nominal value, which are offered for sale by auction or tender. The dividend payable on this new capital is limited to 6 per cent., except as to the £3000 above mentioned, upon which the order places a maximum dividend of 5 per cent. In the event of the profits being insufficient to pay the full amounts of the prescribed rates of dividend, a proportionate reduction "shall be made in the dividends payable on each class." Upon this additional capital the company are empowered to create debenture stock to the extent of £4750. Clause 22 enacts that as from the 1st of April, 1903, the water supplied by the company shall be constantly laid on under pressure. This order will require confirmation by Parliament.

At a recent meeting of the Merthyr Waterworks Committee it was recommended that £65 be paid Messrs. Holmes and King, contractors, on account of the repairs of the Lower Neuadd reservoir; also £288 to the same firm on account of the constructional work at the Upper Neuadd reservoir. It is proposed to stock the reservoirs with fish.

The prospect of the Barrow Water Bill being carried through Parliament is giving considerable satisfaction to a good many of the inhabitants of the neighbourhood of the proposed waterworks. In Ulpha, Seathwaite, Dunnerdale, and the higher parts of the Duddon Valley generally, it is expected that the spending of so much money by the Corporation of Barrow will prove to be a very great boon to the district. There is some reason to believe that this big water scheme may help on the agitation for a narrow-gauge railway in the district.

At the last monthly meeting of the Cirencester Urban District Council, the report of the Water Committee detailing repairs and extensions necessary at the waterworks, involving an expenditure estimated at £3000, the consideration of which was postponed from the last meeting, was brought up, and its adoption moved by the Chairman, and seconded by Mr. F. Cripps, both of whom expressed the conviction of the Committee that the works recommended would render the works completely efficient, and by the duplication of the machinery a practically inexhaustible supply would be available, free from all risks of stoppage from breakdowns. The motion, which also included authority to the Committee to seal a contract for the enlarged boring (estimated to cost £349) was, after a short discussion, unanimously agreed to.

There is now some hope, we understand, that the long-deferred question of making provision for an ample supply of water for the Rhymney Valley will become an absolute fact. During the past few weeks machinery has been conveyed on to the site of the works, and nearly fifty workmen's huts have been built there to accommodate the men. We understand that the larger of the three reservoirs will be proceeded with first. This is situated about three-quarters of a mile above the Rhymney Bridge Station, and when completed will dam back a tremendous volume of water, computed to be sufficient for a three months' supply to the whole of the Rhymney Valley. The two smaller reservoirs will be the same distance above this point. The entire works will involve an expenditure of close upon £25,000. It is expected that the one section will be completed within a year, and that the whole will be ready in about two years. Residents of the valley may therefore look forward with some confidence that the droughts experienced in years gone by will soon be at an end.

LIGHTING.

The Walthamstow Urban District Council has resolved to light the town hall, public library, baths, and technical institute by electricity.

The Southwark Electric Lighting Committee is considering the question of the extension of the Newington electric lighting order over the whole area of the borough.

The Rotherham Corporation electricity generating station in Rawmarsh-road has been formally opened by Mr. D. L. Winter, the chairman of the Electric Lighting and Tramways Committee. The new buildings have been erected at a cost of £24,500.

The financial year of the Glasgow Corporation Gas Department ended May 31st, but it will be a month before the Committee meets to definitely fix the price of gas for next year. It is, however, understood that the Committee does not intend to alter the rate which was fixed last year at 2s. 6d. per 1000 cubic feet.

The Greenwich Borough Council has disapproved of a Provisional Order being granted to the City of London Electric Lighting Company, Limited, to supply electric energy for all purposes in the borough.

Considerable progress has been made in the erection of the new lamp standards on the Thames Embankment. When completed, and the electric light switched on, this will be the best lighted thoroughfare in London.

The Enfield District Council has received a letter from the Joint Committee stating that the total cost of the East Middlesex Electricity Bill was £1205 17s. 8d. Enfield's share was £241 3s. 6d. The Finance Committee's recommendation for payment was adopted.

Mr. H. P. Boulnois, M. Inst. C.E., held a Local Government Board inquiry at Liverpool last week. The subject matters are the applications by the City Council for sanction to borrow £300,000 for the purposes of electric lighting, and £24,000 for the provision of public baths.

At an extraordinary meeting of the Charing Cross and Strand Electricity Supply Corporation, Limited, the chairman presiding, a resolution was passed authorising the directors to raise or borrow such sums as were necessary, to the maximum of £500,000, for the purposes of the corporation's City undertaking.

The Electricity Committee of the Manchester Corporation last week had before the members the tenders for boilers, engines, and electrical work for the Stuart-street Station. The tender for boilers was given to Messrs. Babcock and Wilcox, and the tender for the remainder of the plant went to the Electrical Company, London.

Reigate Parish Church has led the way in the district in the matter of electric lighting. Gas lighting is said to be unsatisfactory for churches, but one cannot help feeling that the adoption of the incandescent mantles would greatly improve the dim, religious glow, which, however effective in an old and time-mellowed building, does not compensate for the struggle to read.

The Leamington Corporation intends to promote a Bill shortly to enable it to withdraw from the purchase of the local gasworks, which it has pledged itself to buy. This can only be done by private Act of Parliament. It is one of the first matters to which the newly-appointed Town Clerk of the borough will have to direct his attention. Since deciding to purchase, the Corporation has realised through the outcry of the ratepayers that it would be much more advantageous not to municipalise the gas; hence it is going back upon its resolution.

The Southwark Borough Council has decided that the Board of Trade be informed that the Council intends to actively oppose the granting of a provisional order to the City of London Electric Lighting Company to empower the company to supply electrical energy for all purposes throughout the whole area of the borough; that the Committee be authorised to obtain the opinion of counsel with regard to the powers of the Corporation to supply electrical energy in parts of the borough other than Newington for street lighting and other municipal undertakings.

At the last meeting of the Deptford Borough Council the Electrical Committee reported that it had considered a letter from the City of London Electric Lighting Company, Limited, giving formal notice of their intention to apply to the Board of Trade for a Provisional Order to empower them to supply electric energy for all purposes throughout the whole area of the metropolitan borough of Deptford. The Committee recommended that the City of London Electric Lighting Company be informed that in the event of their proceeding with the proposed application the Council would oppose it. The recommendation was agreed to.

GENERAL.

The Market Harborough Urban District Council is about to erect a new cattle market and slaughter-houses.

The Manchester Corporation has decided to spend £21,000 in constructing underground conveniences in various parts of the city.

The memorial stone of an extension of the Marine Promenade at Aberystwith was laid last week by the Mayor (Mr. Edward Price Wynne). The extension will cost £13,000, and will be a substantial affair.

A Local Government Board inquiry was held at the Public Offices, Egremont, Cheshire, on Monday last, with reference to the application of the Wallasey Urban District Council to borrow £15,500 for purposes of hospital extensions.

The Wandsworth Borough Council, at the recommendation of the Public Health Committee, has unanimously decided to engage two women for one day a week to assist the Inspector under the Sale of Food and Drugs Act in procuring samples for analysis.

The Mayor of Richmond, Surrey, laid the foundation stone of the new infirmary and nurses' home at Richmond, on Wednesday in last week, which is to be erected by the local guardians at a cost of £40,000. A special feature will be the open-air treatment of consumption.

Plans are being prepared, and will shortly be submitted to the London County Council, for the erection of homes for the working classes in the Limehouse district. We understand it is intended to provide accommodation for over a hundred persons, and the estimated cost is £6000.

Colonel J. T. Marsh, R.E., an Inspector of the Local Government Board, recently held an inquiry at the Council Chamber relative to an application by the Southampton Town Council for permission to borrow the sum of £930 for purposes of street improvement, and £152 for the purposes of public baths.

In view of the possibility of the introduction of plague into Scotland, the Local Government Board, with the object of assisting in the identification of that disease in suspicious cases on board ship, or in the earliest suspected case or cases newly developing in any district, has arranged for bacteriological testing, without cost to the Local Authority, of material from such cases. This material can be received only from the Medical Officer of Health.

Dr. Bulstrode, of the Local Government Board, has been staying some days in Falmouth conferring with the Port Sanitary Authority as to precautions against the introduction of plague, and generally as to the sanitary inspection of vessels. The experience gained by the Board, from inquiries at ports where outbreaks of imported sickness has occurred, seems to point to rats as the most common medium of such importation, and special steps are accordingly being taken to stop the immigration of foreign rats.

Edinburgh Town Council recommitted to the Public Health Committee last week the question of the arrangements to be made for the bacteriological diagnosis of disease. The proceedings of the Public Health Committee are veiled in obscurity, and they are not as explicit as might be wished in setting forth, for the benefit of the Council and the ratepayers, the considerations that induced it to make the recommendation which it addressed to the Town Council. The effect of that recommendation is that the Council should decline all offers of extraneous assistance in this respect, on the ground that the responsibility lying on the Corporation with regard to the public health of the city can only be met by having a complete bacteriological laboratory in connection with the new City Hospital.

A Local Government Board inquiry has been held at Ryde into the application of the Town Council for sanction to borrow £600 for the purchase of horses, harness, and dust carts for scavenging purposes.

The London County Council has convened for Friday, the 28th inst, at Spring-gardens, a conference between its own representatives and delegates from the Metropolitan Borough Councils on the subject of the improved housing of the working classes.

At a recent meeting of Edinburgh Town Council, it was stated that the Medical Officer of Health reported the cost of the preventive measures in connection with the small-pox scare at £3207. Sir Henry Littlejohn suggested that Edinburgh Town Council should promote a Bill to provide for re-vaccination periodically. That was an important suggestion which he suggested should be remitted to the Health Committee. The suggestion was adopted.

We are informed that the East Ham electric tram system, which is owned by the Local District Council, is now practically completed, and that the trams would be running in the course of a few days. The system runs from Manor Park to North Woolwich, through East Ham and Becton, and will join with the Ilford Council's system at one end and the West Ham Corporation's system at the other. When the joint schemes are completed there will be a network of tramways more than thirty miles in extent over these three great "sleeping grounds" of London.

The Corporation of Taunton has led the way in so many municipal enterprises that a refuse destructor might be expected to be already installed in the town. The first step towards the erection of what is considered an essential to the proper equipment of a public health department has now been taken, and the Local Government Board has been asked to sanction the expenditure of £4500 upon a destructor to be erected at the sewage works. Taunton was the first municipality in England to establish electric lighting works, and at the present time extensive alterations are going on at the sewage works to adapt the mode of treatment to the septic tank method.

Mr. Cowan, one of the Local Government Inspectors, held an inquiry in Dalkey last week respecting an application by the District Council for two loans of £2800 and £2200 for the concreting and rekerbing of footpaths and the erection of working-class lodging-houses. Evidence was given that the Council had a borrowing power of £21,000; that the proposed houses were badly wanted, as many of the poorer inhabitants were living in most wretched dwellings, and that they would be let at 3s. 6d. a week. One member of the Council would tolerate the houses, but objected to improving the footpaths, as a "ridiculous and nonsensical scheme," while another took exactly the opposite view, and objected to the houses, but would concede the footpaths. The inquiry then closed.

Last week a conference of the committee appointed from the burghs of Alyth, Blairgowrie, Coupar Angus, and Rattray to consider and report as to the probable cost of a joint infectious diseases hospital for these burghs, and a suitable site, was held in the office of Mr. J. B. Miller, Town Clerk, Blairgowrie. All the burghs were represented, and Provost Templeman, Blairgowrie, presided. It was agreed to recommend to the various Councils that a site of 2½ acres or thereby, on ground belonging to Mr. James Stewart, to the eastward of Old Rattray, and adjoining the public highway leading to Alyth, should be procured, the annual feu-duty to be £10 per acre, no compensation or duplicand being payable. Several of the other proposed sites precluded, by their situation, gas lighting being attainable, and in some of them the expense of getting rid of the sewage would be considerable.

The Annual Congress of the Sanitary Inspectors' Association of Scotland will be held at the Burgh Court Hall, Glasgow, on June 28th. Councillors James Dick and Battersby are to attend as representing the Glasgow Health Committee, and the Corporation is to entertain the members to luncheon.

PERSONAL.

Mr. F. O. Combridge has been appointed Clerk of Works to the Chelmsford Town Council.

Mr. C. W. Thompson has been appointed Inspector of Nuisances for Ridley, at a salary of £60.

Mr. G. F. Dickson has been appointed Medical Officer of the Potton district of Biggleswade.

Dr. F. Edmunds has been appointed Medical Officer to the Chesterfield School Board, at an annual salary of £40.

The salary of Dr. Williamson, Sanitary Inspector of Edinburgh, has been increased from £400 to £500 per annum.

Dr. Sparks has been appointed Medical Officer for the urban district of Whitley, in room of Dr. Alexander, deceased.

Mr. J. H. Sagar, Assistant Borough Surveyor, Stoke-on-Trent, has been appointed Assistant Surveyor to the Poplar Borough Council.

Mr. G. C. Bull, of Turvey, has been appointed Medical Officer for No. 9 district of Newport Pagnell, in succession to Dr. Cock, resigned.

Mr. F. Wilson, of Hampstead, has been appointed Assistant Inspector of Nuisances for Enfield at a salary of £100 per annum, rising to £130.

We hear that the prosperous business of Messrs. Ham, Baker, and Co., of Grosvenor-street, Westminster, has been converted into a limited liability company.

The Local Government Board has sanctioned the appointment of Dr. Tuxford and Mr. Stephenson as Medical Officer and Sanitary Inspector respectively for Boston.

Mr. Amos D. Shrives, Sanitary Inspector, Farnborough, has been appointed Sanitary Inspector to the Guildford Rural District Council at a salary of £150 per annum.

Mr. W. Trevor, Dewsbury, chief assistant-engineer, City of Gloucester Electricity Works, has been appointed Resident Electrical Engineer for the borough of Sutton Coldfield.

Mr. Stilwell has resigned his position as Surveyor for the Rural District Council of Rochford, and Mr. J. Sidwell, of the Blean Rural District Council, has been appointed in his stead.

Mr. John L. Kirkup, Assoc. San. Inst., for 3½ years road foreman for Aldershot District Council, has been appointed to a similar position by the Felling District Council. Mr. Kirkup is well known in Wingate and Lanchester district. He received a timepiece and spirit level from the men at Aldershot on his departure. The District Council also gave him a testimonial.

A difficulty has arisen in connection with the appointment of Dr. A. Underhill as Medical Officer at West Bromwich Workhouse, which was made at the last meeting of the Board of Guardians. Dr. Underhill is at present Medical Officer for Tipton, and the regulations of the Local Government Board, it is said, forbid the appointment of a Medical Officer in a parish when he already holds a similar position in another district. Under the circumstances the Department have intimated that the West Bromwich appointment will not be sanctioned unless there are very strong grounds for doing so.

FORTHCOMING MEETINGS.

JUNE.

Saturday 8th.—Sanitary Institute—Lecture to Sanitary Officers at Yorkshire College, Leeds; Dr. W. Lovell Hunter on "Scavenging and Refuse Disposal; Smoke Abatement." 3 p.m.

Saturday 8th.—British Institute of Certified Carpenters—Visit to Kew Gardens. 3 p.m.

Saturday 8th.—Northern Architectural Association—Visit to Hexham.

Friday 14th.—Institution of Electrical Engineers—Conversazione at the Natural History Museum, Cromwell-road. 9—12 p.m.

Saturday 15th.—The Sanitary Institute—Lecture to School Teachers, Parkes Museum. 10 a.m.

Saturday 15th.—The Sanitary Institute.—Lecture to Sanitary Officers, at Yorkshire College, Leeds, at 3 p.m. "Drainage; Inspection of Builders' Work and Domestic Sanitary Appliances," by W. Spinks, Assoc. M. Inst. C.E.

Wednesday 19th and Thursday 20th.—Institution of Civil Engineers—Conversazione at the Institute, Great George-street, Westminster. 9 p.m.

Saturday 22nd.—The Sanitary Institute—Lecture to Sanitary Officers, at Yorkshire College, Leeds, at 3 p.m. "Sanitary Inspectors' Work (General and Recapitulatory)," by J. R. Kaye, M.B.

Friday 28th and Saturday 29th.—The Sanitary Institute—Examination in Practical Sanitary Science, Practical Hygiene for Teachers, and for Inspectors of Nuisances, Bradford.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2219.—Combined Drain or Sewer.—"Surveyor" writes:—"A drain which receives the drainage from two houses in my district is constructed with common pipes, and is stopped up. The owner refuses to repair, stating that it is a sewer. The two houses belong to one owner, but there is only one gully, which is in a yard common to both houses."

Answer.—The drain referred to is a private drain, belonging to and vested in the owner, and the Local Authority should serve notice upon him under Sec. 23 of the Act of 1875 to provide a sufficient drain or drains, to be of such materials and size, and to be laid at such level and with such fall as, on the report of their surveyor, may appear to them to be necessary.

2220.—"Sanitas Sanitatum Omnia Sanitas."—"H. J." writes:—"I should be glad if anyone can inform me where the following phrase was used by the late Lord Beaconsfield, viz., '*Sanitas Sanitatum omnia Sanitas.*' I believe it was in one of his speeches."

Answer.—We have no doubt some of our readers can furnish the particulars asked for, and invite their replies for our next issue.

2221.—Examinations in Practical Sanitary Science and for Surveyors.—"Gwalia" writes:—"I have just received the certificate of the Sanitary Institute for Inspector of Nuisances, and am an acting Inspector in a wide rural district. I would like to continue my studies, and ask for your advice as to what would be the most suitable examination to go in for next?"

Answer.—We advise the querist to study for the examination held by the Sanitary Institute in Practical Sanitary Science, which goes beyond the scope of the Inspector's examination, as far as relates to practical sanitation, and a more thorough knowledge of the latter is required in candidates for the examination. On passing the examination successful candidates are entitled to the privileges of members of the Institute, and to the use of the letters "Mem. San. Inst." Having passed this examination, the querist may, if he still desires to pursue his studies, prepare for the examination held by the Incorporated Association of Municipal and County Engineers, particulars as to which may be obtained from the Secretary, Mr. Thomas Cole, 11, Victoria-street, Westminster, S.W.

2222.—Pan Closets: Improper Soil-pipe Ventilators.—"A. S. I." writes:—"I should be glad if you would advise whether my Council can compel an owner of a certain house in which there is a pan closet, the tenants of which house say they have not noticed any smell from such closet, to substitute a wash-down or other sanitary closet. Also, can they compel a person to carry a soil-pipe ventilator above the eaves of the roof full bore 4in., as there are many ventilating pipes in my district which are ventilated by a pipe of smaller diameter above the w.c. junction?"

Answer.—As regards existing houses, the Sanitary Authority would have to prove the existence of a nuisance or the insufficiency of the existing arrangement, before they could in each of the cases named require the removal of the apparatus referred to.

2223.—Dwelling-house in such a State as to be a Nuisance.—"T. W." writes:—"In the case of a private house, or of an unregistered lodging-house, which is in a dirty condition, can the owner be compelled, under Secs. 91 to 94 of the Act of 1875, to cleanse the floors and bedclothes in addition to limewashing and cleansing the room?"

Answer.—The owner cannot be required to do any of the things mentioned under the provisions of Secs. 91 to 96 of the Act of 1875. It is only the occupier who is responsible, and notice should be served upon him. In determining upon whom notice should be served to abate a nuisance, the provisions of Sec. 94 of the Act should be closely followed. This section provides that the notice shall be served "on the person by whose act, default, or sufferance, the nuisance arises or continues," provided that, "when the nuisance arises from the want or defective construction of any structural convenience, or where there is no occupier of the premises, notice under this section shall be served on the owner." In the case named by the querist, the occupier is the person "by whose act, default, or sufferance, the nuisance arises or continues," and he is responsible. There is no structural defect which would render the owner liable. The occupier may be required to do all the things named to abate the nuisance.

2224.—Cleansing Dirty Houses: Upon whom Notice to be Served.—"W. L." writes:—"(1) I am making a house-to-house inspection in my district. In some cases I find the plaster on the walls and ceilings is in a defective condition, having fallen off in patches and scales owing to its impoverished condition, thereby rendering it almost impossible to properly limewash such walls and ceilings. On whom should I serve notice to repair the plaster and afterwards cleanse by limewashing the walls and ceilings? (2) A tenant has been in one house upwards of five years. During that time the walls and ceilings have become dirty. Who ought to be made to cleanse in such a case, the tenant or the landlord?"

Answer.—(1) This is not such a nuisance as can be dealt with under the Public Health Acts, and a notice to repair plaster on walls could not be enforced. (2) The notice should be served on the occupier, as he is the person "by whose act, default, or sufferance the nuisance arises or continues." See Sec. 94 of the Act of 1875.

2225.—Veterinary Charts showing Internal Organisation of the Ox.—"R. H. W." writes:—"I believe there is a book published on the ox, showing in a sort of atlas fashion its internal arrangement; that is, you can lift up a page which represents the side of the animal, and there is exposed the inside. In the same manner the various organs may be lifted up, showing both inside and outside. It is essentially a book for meat inspectors, and I believe is published at about 5s.; but, unfortunately, I do not know the publishers or the author. Can you please advise me on the subject?"

Answer.—The book required is doubtless Professor G. T. Brown's "Anatomical Model of the Ox," showing its external and internal organisation by means of superimposed plates printed in colours, with descriptive text, strongly bound in stiff covers, price 3s. 6d. net. Similar anatomical models are published of "The Horse," by George Fleming, F.R.C.V.S., price 3s. 6d.; "The Sheep," by Professor G. T. Brown, price 3s. 6d.; and also "The Dog" and "The Pig." Any of the books may be obtained post free, at the prices named, from the office of this journal.

2226.—Private Streets Works: Adoption as Highway does not Prevent Recovery of Instalments.—"A. B. C." writes: "Some private streets have been sewered, levelled, paved, and flagged under Sec. 150 of the Public Health Act, 1875, by the Council. The apportionments have been made, and two yearly instalments have already been paid. Six months ago the Council declared these streets public highways in the usual manner. One of the owners of property now declines to pay his apportionment, and states that as we have declared the street a highway we cannot recover. Would you advise whether his contention is correct?"

Answer.—The owner's contention is quite incorrect. The practice of adopting private streets as public highways before the owners have recovered the entire cost of making up the street under Sec. 150 of the Act of 1875, or under the Private Street Works Act, 1892, is general in most districts, and does not in the least

affect the power of a Local Authority to recover the expenses as private improvement expenses. Proceedings should be taken against the owner under Sec. 257.

2227.—Purveyor of Milk: What Constitutes such?—"Inspector" writes:—"A person holding charge of a refreshment bar at (a teetotal) working men's institute sells glasses of milk over the counter for his own profit. It is pointed out to him by an Assistant Inspector of Nuisances that the law requires him to register himself as a 'purveyor,' and he is supplied with form of application for the purpose. He refuses to register on the ground that he does not come within the law, and that many others in surrounding districts, hotel keepers, inn keepers, coffee-house keepers, and caretakers of similar institutes, are allowed to trade unregistered. I, the Inspector, apply to my Council for leave to summons. The Council's legal adviser cannot certainly say if the man is a 'purveyor' or not, but dissuades the Council from acting on the ground that there is no legal decision as to the man's position, and that the Justices might not convict. The question is adjourned. (1) Am I right in my report that this man is a 'purveyor' of milk within the meaning of the law? (2) Is there any ruling decision in point? (3) Is this man's case on all fours with that of an inn or hotel-keeper supplying glasses of rum and milk or milk and soda, or milk alone to people staying in his house? (4) Or to the general public at the public bar? (5) Or if there are distinctions what are they?"

Answer.—(1 and 2) We doubt whether a person who occasionally sells milk over the counter in such a case as that named can be deemed to be a "person who carries on the trade of a purveyor of milk," and whether he contravenes Section 6 of the Dairies, Cowsheds, and Milkshops Order, 1886. In Southwell *v.* Lewis, 45 J.P., 206, where a farmer who kept cows for the supply of his family and for amusement, and who occasionally allowed his neighbours and a dairyman to have a few quarts of milk, it was held that he was not a cowkeeper or dairyman within the corresponding provision of the repealed Order of 1879. Field, J., said, "if there had been a regular and continuous supply of milk it might have made a difference." Now, in the present case the attendant cannot be said to be carrying on the trade of a purveyor of milk, and there does not appear to be a regular and continuous supply of milk. There is no decision directly affecting this point. (3 and 4) Yes. (5) The conditions are similar.

2228.—Coal-gas: Influence of Temperature and Atmospheric Pressure Thereon.—"X. Y. Z." writes:—"What is the influence of temperature and atmospheric pressure upon the volume of coal-gas? Also what are the effects of temperature in modifying the quantity and quality of gas produced from retort furnaces?

Answer.—The querist is advised to procure Hughes and Richard's "Gasworks, their Construction and Arrangement, and the Manufacture and Distribution of Coal-gas," price 3s. 6d., wherein he will find the subject fully treated upon. The answer is too long for insertion in this column.

2229.—Water Supply Discoloured by Peat: Means of Remedying.—"Aqua Pura" writes:—"On a water-gathering ground in this locality, which is otherwise of an excellent nature, there is a portion of peaty land a few acres in extent, but from 3ft. to 4ft. deep, and gives up undesirable ingredients to the water. It has been suggested that some local means might be adopted to get rid of this peaty matter or counteract its bad influence, apart from the question of digging it all out, which would be too great an undertaking. Have you or any of your readers any knowledge of a means for preventing the said discoloration and acidity which this peaty area gives to the water, apart from excavation or the filtration of the whole supply? Any suggestions would be gladly received."

Answer.—The most effectual remedy is to collect the water from the peaty area separately, and treat it by liming under the supervision of a skilled chemist, so as to secure the proper admixture, for if too much lime be added it increases the solvent action of the water. Or the water may be passed through filter beds composed of an upper layer of sand, or of sand and polarite, and a lower layer of broken limestone. The fine sand intercepts the peaty matter, and greatly improves the palatability and appearance of the water, and the limestone hardens it, so long as it can be kept free from the coating of peaty matter. When this occurs the limestone must be renewed.

2230.—Sewage Scheme: Discharging Effluent into Tidal River.—"Surveyor" writes:—"We propose carrying out a sewerage and sewage disposal scheme. The former will consist largely of alterations to old work. There is no land provided, and none available unless pumping be resorted to. The present outlets are into a tidal river, on which is the harbour. Will the Local Government Board be likely to approve the scheme without passing the effluent over land before discharging into the tidal river?"

Answer.—The querist omits to give us any particulars of the proposed mode of treatment of the sewage preparatory to its discharge into the tidal river. If the query is directed to ascertain whether the Board would sanction a sewerage scheme wherein the sewers are intended to discharge directly into the river, we advise him that the Board would not approve such a scheme. If, on the other hand, it is intended to provide either septic or detritus tanks and bacteria filters, without passing the effluent over land, such a scheme would, we think, meet with the Board's approval.

STANLEY
Government Contractors.
Makers of Mathematical, Drawing and Surveying Instruments of every Description.
Gold Medals at the Great Exhibitions. Catalogues post free.
Address: W. F. STANLEY & CO., LTD.,
Great Turnstile, Holborn, London, W.C.

WASTE WATER CLOSETS
Easy access, powerful flush.
SANITARY TUBES
3in. diam. to 42in. diam.

THE CONSTRUCTION OF ROADS, PATHS, AND SEA DEFENCES.

By Frank Latham, C.E.

(Borough Engineer and Surveyor, Penzance. Author of "The Sanitation of Domestic Buildings," &c.)

(*Continued from page* 488.)

CHAPTER II.—THE NECESSITY OF GOOD ROADS FOR TRACTION.

Sir Isaac Newton, writes Parnell, "has laid it down as a general principle of science, that a body, when once set in motion, will continue to move uniformly forward in a straight line by its momentum, until it be stopped by the action of some external force. This proposition is admitted and adopted by all natural philosophers as being perfectly true, and, therefore, in order to apply it to roads, it is necessary to inquire what kind of external forces act in a manner to diminish and destroy the momentum of carriages passing over them."

Sir Henry Parnell remarks, "As a carriage for conveying goods or passengers when put in action becomes a moving body, in the language of science, the question to be examined and decided is, how a carriage when once propelled can be kept moving onwards with the least possible quantity of labour to horses, or of force of traction."

Each of these great philosophers admits that some more or less controllable influences are constantly at variance with the principle of science known as the "first law of motion," and that the causes thus offering resistance should be ameliorated to as great a degree as possible. In this respect due regard must also be given to the necessary requirements for the comfort and safety of those that produce the propelling force to such traction, as well as keeping the object in view of reducing the force of traction.

Resistance to rolling is principally due to four causes, viz., surface protuberances and irregularities, surface and wheel friction, surface grades, and wind pressure.

Surface protuberances and irregularities.—When a wheel comes in collision with any hard road obstruction, it becomes necessary for a horizontal force to be exerted at the axle, to raise such weight carried by the wheel to a height equal to that of the obstacle to be drawn over. In comparing a road of considerable protuberances and irregularities with one of smooth surface, the comparative loss of energy in drawing a heavy load must be a matter of no little moment. These irregularities are further responsible for resistance caused by the shocks, which are greater when a vehicle is drawn at a high speed than at a low one.

On ordinary hard roads the resistance attributable to the actual raising of the weight over trifling obstructions is, perhaps, less to be taken into account than that responsible for the concussions that take place as the load is drawn over roughly paved surfaces, and in which, as M. Morin determined in his experiments, the resistance to traction is increased with the speed.

In the case of the want of uniformity in the road surface the resistance may readily be arrived at by the application of the following formula:—

Let P = the force required.
W = the weight, for example taken at 300 lb.
R = the radius of wheel ,, 30in.
O = the obstacle ,, ,, 2in.

then $$P = W \frac{\sqrt{R^2 - (R - O)^2}}{R - O}$$

$$\therefore \quad P = 300 \frac{\sqrt{30^2 - (30 - 2)^2}}{30 - 2}$$

Springs to vehicles have a tendency to diminish the resistance offered by road inequalities at high speeds. Mr. Codrington says regarding this: "The effect of springs in reducing draught is that they enable the wheels to rise and fall over inequalities over the road, while the load on them moves forward without being sensibly raised. The more perfect the elasticity of the springs in a vertical direction the greater is the reduction of draught, but any elasticity in the direction of the traction tends to increase the draught."

Surface and wheel friction.—This form of resistance varies according to the material used, whether it be hard or soft; also, to some extent, according to the size of the wheel. On soft roads the wheel will, to some extent, penetrate the surface, so that when in motion it will be obstructed by a force in front of it of either grit, dust, or by the weight of the vehicle causing an indentation sunk in the material itself. This, consequently, has the constant effect of causing the wheel to climb an irregularity equal to the depression so formed. The amount of penetration is less for large wheels than for small, but it is sufficient for general purposes, and for wheels of ordinary sizes, to calculate the resistance thus caused by penetration by the weight multiplied by a ratio to be determined on by the nature of the road surface, whether it be hard, soft, or medium. The following tables are the results of experiments by Sir John Macneil (made with an instrument he invented for the purpose), as to the resistance to traction of various descriptions of roads.

A wagon weighing 21 cwt. was used on different kinds of roads with the following results:—

	lb.
On well-made pavement the draught is.. ..	33
On broken stone surface, or old flint road ..	65
On gravel road	147
On broken stone road, upon rough pavement foundation	46
On broken stone surface, upon a foundation of concrete formed of Parker's cement and gravel	46

The following empirical formulæ is given by Sir John Macneil for calculating the resistance to traction on level roads for (i.) a stage wagon; (ii.) a stage coach:—

P = force required.
W = weight of vehicle in lb.
w = weight of load in lb.
V = Velocity feet per sec.
C = A constant number depending upon the nature of the surface over which the carriage is drawn.

Then $$P = \frac{W + w}{93} + \frac{W}{40} + C V \quad \ldots \quad \ldots \quad \text{(i.)}$$

and $$P = \frac{W + w}{100} + \frac{W}{40} + C V \quad \ldots \quad \ldots \quad \text{(ii.)}$$

The value of C is as follows:—

On timber surface	C = 2
On paved surface	C = 2
On a well-made broken-stone road	C = 5
On a well-made broken-stone road, covered with dust	C = 8
On a well-made broken-stone road, wet and muddy	C = 10
On a gravel or flint road, in a dry, clean state	C = 13
On a gravel or flint road in a wet and muddy state	C = 32

Example:—To find the force necessary to move a stage coach at a velocity of 10ft. per second, the coach weighing 1500 lb. and carrying a load of 700 lb., and the surface of the road being well-made of broken-stone, but wet and muddy.

Then, according to (ii.)

$$\frac{1500 + 700}{100} + \frac{700}{40} + (10 \times 10).$$

Grades.—Surface grades bring into account the additional force of gravity.

The tractive resistance due to the grade is that force

which is necessary to support a wheel on an incline and to prevent it from running down, under the pressure of its load + the effects of friction.

Therefore the total tractive resistance to be arrived at is, the sum of a given load hauled over a level road + the extra force required to draw the same load up to a graded road.

The following diagram (Fig. 1) is to represent a wheel C loaded with a weight W.

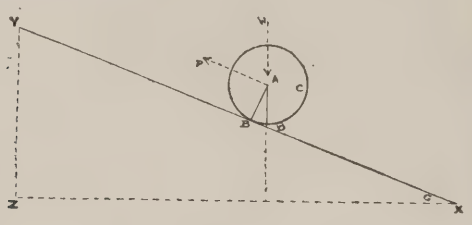

Fig. 1

The wheel is in contact with the inclined plane X Y at B, and P is the force required to haul the load up the incline, and acting parallel to the road.

The wheel is maintained in position by these forces, viz., W, which at all times acts in a vertical direction. By the force P, which is the applied power parallel to the inclined plane, and by the pressure caused by the weight of the vehicle on the road's surface at B, and which is effected by a perpendicular from the point A with the inclined plane X Y.

Draw the vertical base X Z and the horizontal line Y Z, then the relative magnitude of the three forces at P, W and D may be determined.

Because A D and Y Z are parallel and are cut by the line X Y, then the angles A D B and X Y Z are equal, and the angle A B D is equal to the angle X Z Y, being both right angles, therefore the remaining angles B A D and Y X Z are equal, and the triangles X Y Z and A B D are similar.

Now, as the sides of the triangle A B D are proportional to the three forces by which the vehicle is sustained, so also are the three sides of the similar triangle X Y Z, viz.: X Y is proportional to W, Y Z to D, and X Z to the pressure B.

i.e. W : X Y : : D : Y Z,
and W : X Y : : B : X Z.

Therefore if to X Z such a value be allotted that the vertical rise of the road is exactly 1ft., then:—

$$D = \frac{W}{XY} = \frac{W}{\sqrt{AG^2 + 1}} = W. \sin G,$$

$$\text{and } B = \frac{W. X Z}{X Y} = \frac{W. X Z}{\sqrt{X Z^2 + 1}} = W. \cos G.$$

In order to ascertain the force required to move a vehicle upon an inclined road (neglecting the effects of friction), divide the weight of the loaded vehicle by the length of the inclined surface, which affords a rise of 1ft., and the quotient will represent the force required.

Again, in order to ascertain the force with which such vehicle bears upon the surface of the same road, the horizontal length of the road is to be multiplied by the weight of the loaded vehicle and the product divided by the inclined length of same, and the result will be the pressure required.

The pressure of a wheel on an inclined road is slightly less than the actual weight, but the difference is very slight on grades of normal inclination.

To ascertain the resistance to the traction of a vehicle being drawn up or down an incline, first determine the resistance on a level road of such load, the surface to be taken as the same as that of the incline. To this result add or subtract, according to whether the vehicle is travelling up or down hill, the force requisite to sustain the same weight on the incline; then the sum of resistance on a level road and the force requisite on the incline will express the force required for ascending the incline, and the difference of the two results will be the force required for descending the incline.

When the grade force is greater than the surface resistance, it may be necessary to apply extra force to check the propelling force.

Mr. D. K. Clark, in the "Construction of Roads and Streets" (Law and Clark), says: "Rolling or circumferential resistance of wheels is equal to the product of the load by the third of the semichord (of the submerged arc of the wheel), divided by the radius of the wheel." He further remarks: "This question is no doubt applicable, with a sufficient degree of accuracy, for any real needs for calculating the resistance of gravel, loose stones, soft earth or clay." He then deduces as follows: That "the circumferential or rolling resistance of wheels to traction on a level road is inversely proportional to the cube root of the diameter," and that in order "to reduce the rolling resistance of a wheel to one half, for instance, the diameter must be enlarged to eight times the primary diameter." M. Dupuit deduced that on macadamised roads of good condition, and on uniform surfaces, "the resistance to traction is directly proportional to the pressure. It is independent of the width of the tire. It is inversely as the square root of the diameter. It is independent of the speed."

M. Dupuit admits that on paved surfaces which give rise to constant concussion, it increases with the speed.

Mr. Thomas Codrington says: "The resistance due to gravity on inclined roads must, of course, be allowed for in all considerations of draught. It is very nearly equal to the gross load divided by the rate of gradient; thus, on a gradient of 1 in 20 the increase of draught due to gravity will be $\frac{1}{20}$th of the gross weight of the vehicle and its load."

Tractive power.—The tractive power of horses is influenced by still another important condition to those stated, and that is the foothold afforded by the surface. The load drawn by a horse, although not generally affected on the level, must be regulated according to the grade and surface of the greatest incline the load is to be drawn up.

Mr. Macneill, in his "Notes" on the "Holyhead Road," remarks to the following effect:—That when the road is not horizontal, the force of gravity is a great impediment to the draught of carriages, and considerably limits the effect which would otherwise be produced by a horse in drawing a load. If it were not for the hills that are usually met with on turnpike roads, one horse would do as much work as four; for it is well known that the force of draught must be commensurate to the steepness of hills. This being the case, it is important that the greatest facilities should be given to render the ascent as easy as possible by paving such grades with suitable materials that would afford the best foothold.

A horse that is able to move a maximum load on a horizontal road of smooth asphalt is only able to draw about one-fifth of the same weight up an inclination of 3 per cent. paved with similar material; whereas the same horse that draws its maximum load on a level macadamised road is able to draw nearly one-half of the same weight up a 3 per cent. incline paved with similar material. A horse that draws its maximum load on a macadamised road provided with smooth asphalt trackways is able to draw nearly one-third of this weight up an incline of 3 per cent. on a similar surface.

The difference between the maximum load that a horse is able to draw on smooth asphalt, compared with that on a good macadamised surface, is about 50 per cent. in favour of asphalt on the level, and the average foothold that a horse obtains on all grades up to 5 per cent. on good macadam as compared with

smooth asphalt, is about 75 per cent. in favour of the former.

The tractive power of horses varies very considerably, according to the work and description of pavements that they have been accustomed to. It is, therefore, difficult to arrive at anything but an approximate idea on this subject.

The force that a horse may exert may be taken as inversely to the rate at which it travels. An average horse that works ten hours a day at a speed of 250ft. per minute, on a horizontal road, should be able to pull a draught of 75 lb. This would be equivalent to lbs. × feet × time (in minutes).

$\therefore 75 \times 250 \times 600 = 11{,}250{,}000$ foot-pounds,

as representing one day's horse work.

The following will show the tractive force as affected by the amount of resistance offered by the road surface. From experiments made by Sir J. W. Bazalgette: Gross load, four tons; speed from four to six miles per hour:—

	Tractive force on the level.
Macadamised surface	40·7 to 42·29 lb. per ton.
Asphalt	39·0 to 39·32 lb. per ton.
Wood	33·62 to 36·63 lb. per ton.
Granite setts	26·2 to 27·0 lb. per ton.

Comparative statement given by Mr. H. P. Boulnois in his "Municipal and Sanitary Engineers' Hand-book," showing the traction upon level roads formed of different surfaces; asphalt being taken as the standard of excellence:—

Asphalted roadway	1·0 —
Paved roadway, dry and in good order	1·5 to 2 0
" " in fair order	2·0 to 2·5
" " but covered with mud	2·0 to 2·7
Macadamised roadway, dry and in good order	2·5 to 3·0
" " in a wet state	3·3 —
" " in fair order	4·5 —
" " but covered with mud	5·5 —
" " with the stones loose	5·0 to 8·2

(*To be continued.*)

SANITARY LAW (A).*

By Trevor Edwards, Esq., West Riding Solicitor.

THE PUBLIC HEALTH ACT, 1875, AND THE MODEL BYE-LAWS THEREUNDER.

I have to speak to you to-day upon sanitary law, confining myself more particularly to the Public Health Act of 1875. As it is always useful to know what foreigners have to say about us, whether in relation to our laws or our habits, I will read you the following opinion, which I came across a few weeks ago, expressed by a sanitarian of continental reputation, and one who is well versed in all sanitary codes of the civilised world. He says: "Of all countries of the civilised world none has a sanitary code so praiseworthy and complete and so precise as England;" and he proceeds to attribute this to the regard we have for our self-interest thus:—

"The code is the work of the nation which has recognised its necessity in its own interest. In the whole country the marvellous results which have been produced can be seen. Thanks to these laws, the rate of mortality has been lowered—the mean duration of life increased—the amount of sickness decreased. They have greatly alleviated the misery in the houses of the poor, who, thanks to sanitary measures, have a better prospect of recovering their health and the means of providing for their subsistence and that of their families."

You who are conversant with the practical working of our sanitary law are probably more impressed with its shortcomings and at times lament that it does not more fully cover the ground of delinquencies in regard to our communal life. In some support of such views, let me read to you the following extract from an interesting little work by Mr. J. Pollard (published by Wm. Blackwood and Sons, Edinburgh and London), entitled "A Study in Municipal Government." Speaking of the sanitary administration of Berlin, the author says:—

"Every house proprietor is bound, when he finds his tenants keeping their dwellings in a filthy state, to warn them to cleanse them forthwith. If they do not, they are turned out without further ceremony. Should the landlord neglect or fail to perform his duty in this respect, a complaint made by the neighbours—a half-penny post card addressed to the proper quarter—will ensure a visit from an officer of the sanitary department. This officer will, if he finds the house filthy, order out the inhabitants, and cleanse it at the landlord's expense. 'But do you not think you interfere too much with the liberty of the subject?' was the natural question. 'Liberty of the subject, mein Herr!' retorted Stadtrath Meubrink, to whom my best acknowledgments for most courteous attention are due; 'Liberty of the subject! May I ask whether your theory of government is not the greatest happiness of the greatest number?' The reply was in the affirmative. 'And have you not power to remove people from their houses when these become dangerous to the health of their neighbours?' 'We have when infectious disease breaks out among them.' 'Ah, but we anticipate you. We know that this dirt will gender and foster fever. We don't care to wait till fever breaks out. It may come in spite of us, through water or milk or otherwise; but we regard all fevers as preventable diseases, and we feel bound in the interest of the community to prevent them where we can. We too respect the liberty of the subject; but we deny the liberty of the subject to make himself or his home a source of danger to the health and life of his neighbours. We are just a little in advance of you in this matter.'"

There was no rational answer to this retort.

I believe that some such regulations will have to be enacted in England, and perhaps the cleansing of Persons Act, 1897, is but their forerunner.

I do not propose on this occasion to dwell upon the various aspects of law, but only to suggest some few ideas which will serve as an introduction to the systematic and more careful study by you of the law which you have to enforce. The Inspector of Nuisances is a creature of statute, and his duties are expressed by statute. In taking up the study of the Act, and especially its execution, endeavour to imbibe its spirit. Its prevailing note sounds out from the word "nuisance." Some dislike the term "Inspector of Nuisances," and prefer the more modern expression "Sanitary Inspector." I think there is very little to choose between them, and should suggest that you be satisfied with the older and more correct title, "Inspector of Nuisances." The word "nuisance" is derived from the Latin word which means harm, injury, hurt. The spirit of the code, therefore, is to prevent or protect from harm, and happy is the Inspector who can fully grasp the extensive and beneficent purport of the great ideal environing the office of an English Inspector of Nuisances.

I cannot to-day attempt any reference to the decisions of the Law Courts, nor indeed to take up the Act section by section, and explain to you what they teach. As I have already said, I purpose rather to introduce the

* Third Lecture delivered to the Health Officers of the West Riding of Yorkshire April 27th, 1901, at the Philosophical Hall, Leeds.

code. Before doing that will you let me remind you of the fact, never to be forgotten by West Riding men, that it was a Yorkshireman, the late Right Honourable J. Stansfeld, M.P. for Halifax, who did great service in laying the foundations of our sanitary code. He not only gave years of his life towards framing and improving the code, but as the first President of the Local Government Board, he administered his office with the enlightenment which his great knowledge of its duties could alone produce.

If I were an autocrat I might be induced to add to the list of duties of an Inspector of Nuisances prescribed by the Local Government Board, something like this:—"He shall systematically read the Public Health Acts, the local bye-laws, and the duties prescribed by the Local Government Board once at least in every year."

As preparatory to taking up the Public Health Act, I advise you to carefully read the admirable circulars issued by the Local Government Board in 1875-6, explanatory of the Acts.

Too much importance cannot be placed upon the systematic perusal of the Act, for it is impossible for an Inspector of Nuisances to carry out his duties unless he knows that Act well. It is not enough that he should get his ideas from the Medical Officer of Health or from the Clerk to the Sanitary Authority. He should have the text of the Act ever at hand, and it will follow from systematic study, his duties will soon become impressed on his mind. As an Inspector he is an executive officer who can only perform certain acts.

In the study of the law I do not advise you in the first instance to get any commentary or treatise upon it, but confine yourself to the Act itself—preferably a King's Printer's copy. The Acts should be provided by the Local Authority as part of the equipment of the department. Having got your Act, let it be well bound, and interleaved with two plain sheets between each page of the Act, and several at the end for general notes. Upon the interleaved sheets note up from time to time any important interpretation of the text, decisions of the Courts, &c., references to other sections or Acts amending or extending it. In that way you will in course of time have a valuable collection of information which will not only assist you in discharging your duties promptly, but will enable you to instruct your assistants with assurance. To the extent that you show yourself master of your work, to that extent you will draw to yourself the respect and confidence of those serving with you.

What I have said as to the study of the Acts applies with equal force to the local bye-laws of your department, which, as you know, are an extension of the Acts. They fill up many details which the Public Health Act leaves to each locality to settle for itself, subject, of course, to the approval of the Local Government Board.

Having provided yourself with the Act, the next point is to learn how to acquire its meaning to the best advantage. In reading through a section of an Act of Parliament one cannot help but be struck by its great verbiage, and it is not easy at first to grasp its central idea. It is advisable, therefore, to pick out the substantive words and italicise them. Take, for example, Section 116, which I would underline as italicised thus:—

Unsound Meat, &c.

116.—*Any* Medical Officer of Health or *Inspector of Nuisances may* at all reasonable times *inspect and examine* any animal, carcase, *meat*, poultry, game, flesh, fish, fruit, vegetables, corn, bread, flour, or milk exposed for sale, or deposited in any place for the purpose of sale, or of preparation *for sale*, and intended for the food of man, the proof that the same was not exposed or deposited for any such purpose, or was not intended for the food of man, resting with the party charged; *and if* any such animal, carcase, meat, poultry, game, flesh, fish, fruit, vegetables, corn, bread, flour, or milk appears to such Medical Officer or Inspector to be diseased, or unsound, or unwholesome, or *unfit for the food of man*, he may *seize and carry away* the same himself or by an assistant, in order to have the same dealt with by a Justice.

The words in italics read as follows:—Any Inspector of Nuisances may . . . inspect and examine . . . meat . . . for sale . . . and if . . . unfit for food of man . . . seize and carry away. Thus by reading only the words italicised or underlined, you may almost at a glance see what is the real purport and subject of the section. Subsidiary underlinings, connecting details, &c., may also be made, provided that the text is not overweighted. This practice will impress upon your mind the provisions of the Act, and incidentally the course of your duty, and if at any time you are in doubt as to whether you ought to take this course or that in connection with any matter of emergency and have not time to consult the Clerk or Medical Officer of Health, a glance at your underlined text will give you greater confidence in your action. Before commencing the study of the sections, carefully consider what appears to be no part of the Act itself—the arrangement of the sections. This shows you the main outlines of the Act, and should be as clearly understood by the Inspector as a map by a war general.

The Act, you will observe, is divided into parts. Part I. is introductory, and Part II. you need not trouble about. Part III., "Sanitary Provisions" is the main part of the Act which affects you. In Part IV., "Local Government Provisions," the only division that you need trouble about is "Markets and Slaughter-houses." The only other portions of the Act that I need refer to are Part VII., "Legal Proceedings," and the first two sections of Part X.

I direct attention for a short time to Part III., "Sanitary Provisions." You will find that it is generally divided into certain groups of sections which deal with different departments of your work, and these groups are further sub-divided into smaller groups. There is, first of all, a division dealing with sewerage and drainage, and the advantage of this is that if at any time you have need to consult the Act upon any question of drainage, you will seek for the information there. The first sub-division relating to sewers and drains, extending from Section 13 to Section 26 requires particular attention at your hands; but the next sub-division, "Disposal of Sewage," needs attention by the Surveyor or Engineer rather than from you. The division headed "Privies, Water-closets, &c.," which comprises only seven sections, is of the greatest importance to an Inspector of Nuisances.

I shall not take up your time by pursuing this line of tuition any further, for I think I have sufficiently indicated the advantage of learning first the structural outline of the Act before entering upon its detailed study. If you have the outline well impressed on your mind you will know how to find your way about the Public Health Act without loss of time. In entering upon the sections, the first one to claim your notice is the fourth, which deals with "Definitions." It is a section of the greatest importance. Almost every word in the English language can be used in a variety of senses; and it is necessary that you, when preparing your reports, or when you give evidence in a Court — indeed, on all official occasions — should employ your words in the sense which they bear in the Act of Parliament. On this occasion I can only give a brief selection. Take the term "Local Authority." The section states that "Local Authority *means* Urban Sanitary Authority and Rural Sanitary Authority.' First I draw your attention to the signifi-

cance of the word *means*. In reading through this section you will observe that at times the word "*means*" is used, and at other times the word "*includes*." These words are selected for an express purpose. Whenever you find that any expression or word is said to *mean* something you may conclude that the definition is exhaustive; for instance, when it is stated that "Local Authority" means Urban Sanitary Authority and Rural Sanitary Authority, we are to understand that it means an Urban and a Rural Sanitary Authority, and no other body, whether it be Parish Council or County Council. Now, on the other hand, when the word *includes* is used, it signifies that the definition is not exhaustive, but mainly indicative. Take the definition of the word "Surveyor." It *includes* any person appointed by the Authority to perform any of the duties of surveyor under this Act—whether he be an actual surveyor or not.

Returning to our definition of "Local Authority," you will understand, then, that whenever the term is used in any section the reference is to both Urban and Rural Sanitary Authority; so that when Section 24 enacts that "where any house within the district of a *Local Authority* has a drain communicating with any sewer, &c.," we know that it refers to houses in Urban or Rural Sanitary Districts. On the other hand, when Section 20 says, "An Urban Authority may, if they think fit, provide a map, &c.," we know that this power is limited to Urban Authorities, and is not conferred upon Rural Authorities, otherwise the words Local Authority would have been used.

Consider now the definition of the word "Owner." It is necessary that an Inspector of Nuisances, especially when serving a statutory notice, should know upon whom to serve it, and unless he is acquainted with this definition he may be in a difficulty.

"Owner" means "the person for the time being receiving the rack-rent of the lands or premises in connection with which the word is used, whether on his own account or as agent or trustee for any other person, or who would so receive the same if such lands or premises were let at a rack-rent."

If at any time you are in doubt as to who is the owner or what the expression "Owner" means, read carefully this definition, together with the following definition of the word *rack-rent*, and I think your difficulty will evaporate.

I would next call your attention to the definition of "Drain," which runs thus:—"Drain" means any drain of and used for the "drainage of one building only, or premises, within the same curtilage, and made merely for the purpose of communicating therefrom with a cesspool or other like receptacle for drainage, or with a sewer into which the drainage of two or more buildings or premises occupied by different persons is conveyed." This definition has given considerable trouble, and the Law Reports contain scores of cases bearing upon it. The difficulty has arisen in applying it to varying circumstances.

(*To be continued.*)

The annual inspection of the Waterworks at Lintrathen by the members of Dundee Town Council took place last Thursday. Early in the forenoon the party, in number about fifty, entrained at the West Station for Alyth, which was reached after a pleasant journey. Thence they were driven to Lintrathen, where the company divided—one portion driving round the loch, while the other preferred to stroll in the beautiful grounds. Glorious weather favoured the party, and a most enjoyable time was spent. Luncheon was served in a marquee recently erected in the grounds. The special train conveying the Councillors and their friends homeward arrived at Dundee about 9.30 p.m.

THE TRURO SEWERAGE DISPOSAL SCHEME.

Although comparatively a small matter in itself, the above scheme has assumed a certain amount of importance to municipal engineers, as it has been made the occasion for a direct attack upon modern methods of sewage treatment. We have ever entertained the belief that the best way for getting at the truth of any matter is to let all sides have a hearing. In fact, it is only by fairly facing the objections to, and weak points of, any system that perfection will ever be attained. Honest criticism should always be welcomed, but if it is advanced merely for selfish purposes it will soon carry its own refutation, and be estimated at its true value.

The city of Truro has recently prepared a sewerage scheme, and this was sent up to the Local Government Board for consideration in the ordinary way. Following this, it was decided to send a deputation to London to consult with the Central Board—a very excellent course to adopt—and also to pay a visit to Sutton, Surrey, and inspect the works there. The reports on these two visits have now been issued, and appeared last week in the *Royal Cornwall Gazette*.

THE DEPUTATION TO SUTTON.

First we will take the report of the Mayor, ex-Mayor, and City Surveyor, who formed the deputation to Sutton, where they were conducted over the sewage works by Councillor Wooton, ex-chairman of the Council. They report as follows:—

The present population of Sutton is 16,000, the average dry-weather sewage flow 500,000 gallons, the sewers being constructed on the separate system. The sewage disposal works were originally designed for chemical precipitation and broad irrigation, and were constructed in 1891-93. Owing to the effluent from these works not satisfying the Thames Conservators within two years of their completion, in November, 1896, the Council, acting on the advice of Mr. Dibdin, constructed the first bacteria bed for the treatment of crude sewage in the United Kingdom. This first bed was constructed by converting one of the chemical precipitation tanks into a bacteria bed by filling it up to 3ft. 6in. from the bottom with burnt clay ballast, and the sewage was applied to it on what is now known as the "Dibdin" or "Sutton" system of filling, viz., to allow the bed to fill nearly to the surface, to stand full for a given period. The effluent is then drawn off, and the bed allowed to stand empty for a given period to allow for aëration of the bed.

The success achieved was so great that gradually since then the whole of the chemical precipitation tanks have been converted into bacteria beds (one of them being utilised to form an open septic tank), and other new bacteria beds have also been constructed.

The works have been gradually extended, and the method now in operation is as follows: The crude sewage passes first through a small detritus tank and is conveyed to the open septic tank, the capacity of which is so arranged that the sewage passes through it very slowly. At the time of our visit a thick septic scum could be seen on the surface of the tank. The solids are all broken down by bacterial agency in the tank; and the effluent we saw coming away from it was practically freed from suspended matter. The open septic tank effluent is then run on to one of the first-contact bacteria beds. The bed is charged nearly to the surface,

after which the supply is stopped and diverted to the next bed. The sewage is allowed to remain in contact with the bed for two hours, after which the outlet valve is opened and the effluent is drawn off, to be similarly treated on the second-contact beds, the effluent from which is in a fit condition to be discharged into the brook. The bacteria beds are charged three times a day, an interval of rest being given of not less than two hours to each bed after its being emptied.

This mode of treatment of the sewage reduces the matters in suspension from 67·2 grains per gallon to 0·0, the oxygen absorbed from 3·517 grains per gallon to 0·578 grains and the albuminoid ammonia from 0·38 to 0·059 grains; whilst nitrification has taken place to the extent of 2·151 grains of nitrogen per gallon. The sludge is absorbed by bacterial agency in the process and does not accumulate or manifest itself. The first bed, put down in 1896, has continued at work almost without interruption without the renewal of the material, and when turned over in our presence was quite sweet and without any accumulation of sludge. Your Committee were very much impressed with the great simplicity of the process, the absence of expensive works and machinery, and with the splendid effluent which was being obtained.

THE CONFERENCE WITH THE LOCAL GOVERNMENT BOARD.

The same deputation met Major-General Phipps Carey, Chief Engineering Inspector, at his office, and the following is given as a *résumé* of the conference:—

General Carey laid stress on the necessity of your Council deciding for yourselves as to what system shall be adopted for sewage purification, as the Local Government Board cannot advise as to what system shall be adopted.

The Local Government Board consider the scheme recently submitted unworkable. Their reasons for rejecting it was not because it was experimental, for, if the scheme had been a practicable one, they might have gone further with it, but they were decidedly of opinion that it was unsatisfactory and insufficient, and, said General Carey, they were satisfied that it would not work at all.

General Carey would not commit himself definitely to advise as to a scheme, but his remarks certainly encouraged a scheme of bacterial treatment, and he urged the advantage in such a scheme of adopting septic tanks as part of the process, as they were peculiarly useful in places where it was necessary to economise fall. They might be either on the lines of the closed septic tanks as adopted at Exeter, or, perhaps better still, the open septic tanks as adopted at Manchester and other places, it having been shown by experiment that it was not necessary to have closed septic tanks. He expressed the opinion that very satisfactory results had been obtained by this process of treatment in septic tanks, and subsequent treatment on aërobic contact bacteria beds.

If, he said, your Council decided to proceed on these lines, on account of the oyster fishery, it would be necessary that the scheme should provide full provision for the settlement in tanks, and further treatment on first contact bacteria beds of adequate capacity in accordance with the requirements of the Local Government Board as to such works. He added, however, that although the Local Government Board had not hitherto sanctioned a scheme on these lines without requiring provision to be made for subsequent land treatment, it was probable that in this case, as the effluent was to be discharged into tidal waters, the Board would waive their usual requirement that land should be provided for final treatment. The only reservation he made to this statement was that they could not, of course, speak for the Board of Trade.

With regard to the proposed site of the works on the mudland below the quay, General Carey raised the objection that it was very limited in area for such a purpose, and did not offer that facility for expansion so desirable in such a works. He also expressed himself as somewhat doubtful as to whether the Local Government Board would approve of this site for the works on account of the close proximity of surrounding houses.

General Carey was questioned as to whether, considering that the effluent would discharge into tidal waters, it would be necessary in the proposed scheme to provide storm water filters to deal with the excess of storm water from three up to six times a dry weather flow in accordance with the present requirements of the Local Government Board. He stated that the scheme on paper must provide for this, and, if not actually constructed, your Council possess the necessary land and facilities for constructing them in connection with the works if required.

As the fall is limited from invert of sewer to low water, General Carey was asked if some additional beds, over and above their usual requirements, could not be provided, so as to make it possible, by means of this excess capacity, to utilise some of the beds for tidal storage, and allow of the bacteria beds being constructed of greater depth than would otherwise be possible, but General Carey expressed himself definitely that all the bacteria beds must have free outfalls at all states of the tides, and, consequently, independent tidal tanks would be necessary.

General Carey definitely expressed his disapproval of the last scheme. He stated that the method of filling or passing through the beds could only produce a straining action, that the beds being air-locked every tide they could not possibly work as bacteria beds, whilst his preliminary tank could not in any way be considered a liquefying tank. The scheme, he said, was not rejected on the grounds simply that it was experimental, but because they considered it was absolutely unworkable.

He considered that some competent engineer should be entrusted with the design of the works.

WHAT "AN EXPERT" SAYS.

On the same day that these two reports appeared in the *Gazette* an article was printed giving the "views" of "an expert" upon the Sutton process. Now ordinary provincial papers do not keep sanitary experts upon their staff, and it would be a little interesting to know whether this "expert" was called in by the editor or whether the opinion was proffered; also how he obtained copies of the reports. In order, we suppose, to emphasise his points, quite a number of words and passages were italicised, but we have dispensed with this, as there is really no need for it. We reprint the article in full:—

The process of sewage treatment and disposal experimented with by Mr. Dibdin at Sutton is called the double-contact system. As designed and worked at Sutton it involves the reception of crude sewage after screening the larger solids through a fine screen* upon a double primary and secondary set of so-called bacterial contact beds, and without precipitation or treatment in tanks. The primary bed is of coarse coke or clinker about 5ft. deep. The secondary beds are of finer coke, and about 4ft. deep. The sewage is run into the primary bed until it is full. This bed is then allowed

* The screened matter has to be removed and disposed of. This often amounts to a very serious quantity. At Leeds it amounted to 500 tons per million gallons daily flow per annum.

rest a certain number of hours. The effluent is then run off into the secondary filter bed, and the primary bed is left empty a certain time and then refilled. The secondary bed is worked similarly. There are generally about three fillings per twenty-four hours.

Theory of the process and expectation regarding its capacity to purify the effluent and deal with the sludge.—The theory of the process is that by allowing sewage to rest in the beds it can, by means of the coke surface, be brought into contact with certain bacteria which not merely liquefy some of the suspended solids but effect a purification in the dissolved matters as measured by the usual albumenoid and oxygen tests.

The original expectation was that (1) the solids usually deposited in a precipitation tank would all be dissolved or disappear in the filter beds, and that the sludge difficulty would thus be ended without tank treatment. (2) It was also supposed that the purification after two contacts would be sufficient.

Results of experiments.—(1) Has been completely falsified from the results of the recent experiments conducted by public officials at London, Leicester, Leeds, and Manchester, representing sewage of all characters, and in which the so-called "Dibdin" or "Sutton" system has been experimented with.

At Sutton.—The system carried out at Sutton is not regarded as a test of anything by the officials of the Local Government Board, nor is the theory of the system admitted by them to be practicable. The objection to allow free access to the works at all times, which prevails there, is also regarded as detrimental to any conclusions in regard to the results assumed to be obtained. It is easy to imagine that a body of municipal officials visiting Sutton and seeing no visible matter in the filter beds, or near the screen, not knowing the strength of the sewage, gazing at a carefully raked filter and being shown a bright effluent from the secondary bed, might imagine the whole problem solved. To those who have time to analyse and investigate there never was a more specious illusion, and it is now universally admitted by all the leading experts —Mr. Baldwin Latham, Professor Percy Frankland, Dr. Rideal, Dr. Clowes, &c.—that quite apart from the question of purification the suspended solids are only very partially dissolved in the filter beds, and that the irreducible residue is so considerable that the beds rapidly sludge up, and that settlement in a preliminary tank is absolutely necessary in order that even a very moderate flow per acre may be practically treated. In fact, the whole theory of the Sutton system has been swept away by the results of practical experiment, and we come back to tanks and tank treatment as a necessary preliminary process. Thus the Manchester experts say. (Report, page 26.) Conclusion :—(1) "The suspended matter must be removed, as far as possible, by sedimentation," and they recommend the use of the "tanks already existing at Davyhulme." Under the heading "Later Improvements," &c., they say "That the sewage passing on to the bacterial beds should, by means of these tanks, be not only free from suspended matter, but also rendered of more uniform character," &c. This means that the tanks are to do the very work which, by the Sutton theory, the double-contact beds ought themselves to do, and which constitutes the only *raison d'être* for the system.

Sludging up of the contact beds.—The necessity for the preliminary tank has arisen out of the rapid sludging, loss of capacity, and choking of the filter beds by the suspended matter. At the following places where the double contact-bed system has been tried the rates of sludging are given as below. These are from several recent official reports.

Double-contact Beds Loss of Capacity.

Place.	Days of working.	Per week as percentage of original water capacity.	Time in which filter completely choked. Months.
Leeds	487	2·1	13
Manchester ...	220	1·0	22
London	525	1·2	19
Average		1·4	18

Filters useless in one and a-half years.—That is to say the filters are completely choked in one and a-half years; even with a domestic sewage like that of London. In the Leeds report it is said, "The real difficulty with contact beds is to maintain capacity." "The hope that accumulations would be dissolved by rest has not been fulfilled at Leeds." Only by working them (the beds) at the rate of one filling of 25,000 gallons per twenty-four hours could the continued life of the rough bed be secured, and even then the ultimate choking seems inevitable owing to the retention in the bed of matters which, although organic,† have reached an irreducible condition, and which could not be consumed by resting the beds." (To show what the above one filling per twenty-four hours in order to avoid sludging would lead to in the way of filter area, it is only necessary to say that the Leeds double-contact beds were equal to half an acre one yard deep. Twenty-five thousand gallons per day on this area would mean that for one million gallons daily flow the filter area would have to be no less than twenty acres.)

At Crossness and Barking.—Dr. Clowes began trying crude sewage on double contact beds *à la* Sutton. He is now trying to diminish the choking by previous sedimentation in tanks. In his last (third) report he says: "A rough process of sedimentation was effected at the southern outfall by allowing the crude sewage to flow through a large tank on its way to the coke-bed. This sedimentation considerably retarded the choking of the coke-beds" (Part III., page i.). He also says: "The acre bed, which receives the effluent from chemically‡ treated and sedimented sewage, has yielded better results than the smaller experimental beds" (which receive crude sewage). It is the same tale all round. The practical objections detailed above are so prohibitive that it is hardly necessary to allude to (2) the purification.

The purification produced by the Sutton process.—In any case this is not great. Measured by the albuminoid ammonia, the first seven months at Sutton¶ gave a total reduction of only 80 per cent. from the crude sewage, and a figure for the second filtrate of 1·6 parts per million, which is not much better than a good chemical tank effluent, and far inferior to that yielded by the single coke filtrate of the same. In London Dr. Clowes got the following for the second final filtrates :—

	Depth. Feet.	Percentege total purification. Albuminoid.	Oxygen.
London (double-contact beds—coke)	5	63	59
Do. (coke)	10	—	76

By a good chemical process the reduction can be 83 per cent. to the tank alone, and 94 to the filtrate, which is far superior to the above. At Leeds a reduction of about 85 per cent. was got from the crude sewage for albuminoid, but the second filtrate averaged about 1·5 parts per million albuminoid, which is below the Mersey and Irwell standard.

The bacteriological and sanitary aspects of bacterial effluents.—The experiments conducted by Dr. Clowes

† This is specially noted so that it is not mere grit or mineral. It shows that the bacteria either cannot tackle some or the organic at all, or else they produce the stuff themselves.

‡ And such chemical treatment only 3 grains to the gallon.

¶ Mr. C. Chambers [Query Mr. C. Chambers Smith] has given figures which show a total purification of 85 per cent. from the crude sewage.

on the Sutton system, and the bacterial examination of the effluents from various double and single-contact beds at Barking and Crossness under the direction of the London County Council, are the most exhaustive yet made, especially in regard to the bacterial character of the final effluent. The final conclusion is stated thus :— "In view of these results only one conclusion seems possible, viz., that . . . the effluents from the bacterial beds cannot reasonably be assumed to be more safe in their possible relation to disease than raw sewage slightly diluted, but otherwise unaltered in its bacterial composition." In popular language the disease microbes occur in the effluents just as much as in the sewage.

It seems impossible to doubt that a thorough chemical treatment in the tanks, by which a large portion of the dissolved, and the whole of the suspended solids (which are assumed to be the chief pabulum of the bacteria) are precipitated to the bottom, would leave an effluent which would not be open to the same objection, and which, while admitting of purification in regard to its dissolved matter by the action of the ordinary saprophytic or non-pathogenic bacteria of putrefaction, would yield a filter effluent which would be probably freed from the pathogenic or disease-causing species. The double or multiple-contact bed system, without previous tanks, known commonly as the "Sutton system," is regarded as dead. It received its funeral oration at the reading of Dr. Clowes' paper before the Society of Arts last year.

MR. DIBDIN REPLIES.

Knowing the interest taken in this matter by our readers, we have thought it wise to bring the above article under the notice of Mr. Dibdin, and to give him an opportunity to reply. Of course, the article shows so much bias that its value is considerably weakened. At the same time, when such statements are made—even anonymously— it is well they should be dealt with at once. We have received the subjoined reply from Mr. Dibdin :—

Sir,—I have read with much interest and amusement the observations by "Expert," printed above, and kindly brought under my notice by you. Since "Expert" is evidently so thoroughly satisfied of the accuracy of his statements that he does not consider it necessary to authenticate them by giving his name, it would, in a general way, be only right to take no notice of the statements made, but in view of the widespread interest on the question and its great importance, no hesitation need be felt in exposing the fallacy under which this disinterested gentleman is labouring.

It would occupy too great space to criticise all the statements in detail. The main points may be summed up in the general conclusion that because two of the old precipitation tanks at the Sutton works have been utilised as grit or sedimentation tanks, therefore the whole system of bacteriological treatment, as opposed to chemical precipitation, followed by sludge pressing, is utterly fallacious, dead and buried! "Expert" exults over the idea that the sewage at Sutton at present passes through a preliminary tank, and evidently assumes that this is equivalent to the tank known as the "septic." The fact is that if the Sutton grit tank was arranged on that system it would have to be about ten times its present size, and then arched over, whilst at present it is only covered with the galvanised iron sheeting, which for some unknown reason was originally placed over all the precipitation tanks, and has been removed from the majority when they were turned into bacteria beds.

If "Expert" had put the shoe on the other foot, and said that the "tank" system, "septic" or otherwise, was a complete failure until the bacteria beds—first worked out and introduced to the public at Barking Creek and Sutton—came to its rescue, and first showed how sewage could be purified effectually without the use of expensive land, chemicals, or sludge presses, he would have been within the facts. For a fact it is, that until the work in connection with the purification of the Thames was undertaken and published, and in connection therewith the bacterial principle definitely enunciated by the writer and Dr. Dupré, adopted and followed up by Massachusetts, and put into practical form at Barking Creek and Sutton, the whole question was in a state of chaos. Sutton, from the first, has been an experimental works on purely scientific lines. The principles originally adopted are those in work to-day. Because trifling modifications are introduced from time to time, it is utterly preposterous for "experts" to talk of the "Sutton system" being *dead*.

Thus far on the general question. There are two statements which show the degree of reliance to be placed on the article: (1) That the officials of the Local Government Board do not regard the Sutton experiments as a *test of anything*. (2) That free access is not allowed to the works at all times.

With regard to (1), whatever may be the opinion of the Local Government Board "officials," it is a fact that the Board have sanctioned numerous schemes based upon the Sutton lines, and that those schemes, as many of your readers are aware, are in successful operation.

With reference to (2), viz., that free access is not allowed to the works, this is absolutely untrue. Any person or persons can obtain access to the works at any time, day or night, or for any periods they may desire, on application to the Engineer to the Council, Mr. C. Chambers Smith, and no notice need be given.

The only reason for asking deputations to arrange as far as possble for a particular day is that when the process was first at work deputations kept arriving at such a rate that the work of the attendants was seriously interfered with, and it became an urgent necessity to ask visitors to keep to certain times in order that the men might get on with their work. If any person, of whatsoever kind or persuasion of thought, desires to inspect the working of the system, he has only to state his business in a proper manner in order to at once obtain full permission from the Engineer to stop on the works for as long as he pleases, and, if desired, Mr. Chambers Smith will at any time issue an undated order to view the works, which may be utilised by the bearer at such date or hour as he, the bearer, may afterwards determine, and moreover empower him to take samples for analysis at any hour—a privilege which very few Local Authorities in the kingdom will allow.

The fact is that the Sutton system, as it is called, has been a heavy blow to the large number of folk whose interests were bound up with this, that, or the other patent scheme. The introduction of a simple and yet unpatented method of overcoming so many of the old-time sewage worries came as a sad shock to many, who are evidently, judging by the tone of "Expert's" article, only too glad to point to any slight modifications, whether improvements or not, and say, "Ha! ha! See, they have altered it. It is not the same in every detail and iota. They are using a grit chamber instead of a screen; they use a syphon instead of a hand-valve. Ha! ha! Their old 'system' is *dead!!* and we have heard its *funeral oration!*"

This puts one in mind of the old joke about the Scotch elder whom his enemies wanted to worry; so they took a coffin to his home, and told him that he was dead and must be buried. "But I'm no dead!" says he. "Yes, you are dead, and here's your coffin to prove it."

To the quotation from Dr. Clowes' report the following should be added, and it must be remembered that the Crossness experiments were not carried out with a view to obtaining the maximum degree of purity possible. "In the biological treatment no chemicals

are required, and no offensive sludge is produced. . . . However desirable it may be to obtain an effluent chemically pure, and, at the same time, bacteriologically above suspicion of danger, a process which leads to the solution of the great mass of suspended matters in the raw sewage, which effects a striking reduction in the amount of putrescible matters, which avoids the use of chemicals and the accumulation of offensive sludge, which yields an apparently non-putrescible effluent, and which is at the same time practicable, is one which presents such singular advantages over chemical treatment, and which produces such satisfactory results in view of all the requirements of the case, that it would be idle to deny its value or attempt to minimise its usefulness simply because it falls short of a standard of absolute perfection."—I am, Sir, yours faithfully,

W. J. Dibdin.

ROYAL INSTITUTE OF PUBLIC HEALTH.

THE FORTHCOMING CONGRESS AT EASTBOURNE.

PROVISIONAL PROGRAMME.

The provisional programme of the arrangements of the Congress of the Royal Institute of Public Health, to be held in Eastbourne next July, has just been issued by the local Executive. It will be noted that the Duke of Devonshire, who is the president of the Association, will deliver an inaugural address. Both the Duke and Duchess are taking the liveliest interest in the arrangements, and their active co-operation cannot but enhance the success of the Congress.

The railway companies will issue return tickets to Eastbourne to delegates at a fare and a quarter. The London, Brighton, and South Coast Railway will issue return tickets from Eastbourne to neighbouring places to delegates at a fare and a quarter during the Congress. Drives will be organised to various places of interest in the town and neighbourhood, and visits in connection with sanitary matters, drainage, &c. Special facilities are being arranged for delegates in connection with entrance to Devonshire Park, the Social and Political Clubs in Eastbourne, the Royal Eastbourne and Willingdon Golf Clubs, the Eastbourne Cricket and Football Club, the Upperton Lawn Tennis Club, the Compton Croquet and other clubs, the theatres, steamers, bathing, &c. A special guide book (with maps) is being prepared for delegates.

THE PROVISIONAL PROGRAMME.

Following is the provisional programme, which will be subject to minor alterations:—

Wednesday, July 24th.

10 a.m. to 4 p.m.—Reception Room, Grove Hall, open for information for delegates, issuing of tickets, &c. This Reception Room will be open daily throughout the Congress from 9 a.m. to 4 p.m. for the purposes above mentioned.

Thursday, July 25th.

9 a.m.—Reception Room open.
3 p.m.—Informal reception of delegates by the Mayor in the Reception Room of the Town Hall.
Delegates and others will wear their chains of office and academical or municipal robes; delegates will robe in Mayor's parlour.
3.30 p.m.—Opening address by His Grace the Duke of Devonshire, K.G., in the Town Hall.
4.30 p.m.—Reception by the Eastbourne Cricket and Football Club in the "Saffrons," adjoining the Town Hall.
8 p.m.—Reception by the Right Worshipful the Mayor and Corporation of Eastbourne.

Friday, July 26th.

9 a.m.—Reception Room open.
9.30 to 1 and 2 to 4 p.m.—Meetings of sections.
4.30 p.m.—Garden party.

Saturday, July 27th.

8.30 a.m.—Reception Room open.
9.30 a.m.—Excursions to Battle Abbey, Arundel, Normanhurst, &c., by kind permission of His Grace the Duke of Norfolk, the Right Hon. Lord Brassey, K.C.B., and others. Excursions by sea to the Isle of Wight, &c.
8 p.m.—Special Concert at the Devonshire Park.

Sunday, July 28th.

10.30 a.m.—Assemble at the Town Hall.
11 a.m.—Special Service at St. Saviour's Church, attended in State. Probable preacher, the Reverend Dr. Merry, rector of Lincoln College, and Public Orator Oxford University.
(Delegates and others will wear their chains of office and academical or municipal robes).

Monday, July 29th.

9 a.m.—Reception Room open.
9.30 to 1 and 2 to 4 p.m.—Meetings of sections.
4 p.m.—Visit to Lewes, and Garden party at Glynde, by kind invitation of Admiral the Hon. T. S. Brand. Special train, 4.15 p.m.
8.30 p.m.—Ball and reception at Devonshire Park.

Tuesday, July 30th.

9 a.m.—Reception Room open.
9.30 to 1 and 2 to 4 p.m.—Meetings of sections.
4.30 p.m.—Closing meeting of the Congress at the Town Hall.
7 p.m.—Congress dinner.

Wednesday, July 31st.

9 to 11 a.m.—Reception Room open. Excursions will be arranged for those delegates remaining in Eastbourne, if wished.

Changes at the Local Government Board.—The President of the Local Government Board has appointed Major-General H. Darley Crozier, R.E., to be Chief Engineering Inspector of the Local Government Board in the place of Major-General C. Phipps Carey, R.E., who has retired. Mr. G. Waller Willcocks, M. Inst. C.E., has been appointed Deputy Chief Engineering Inspector, in succession to Major-General Crozier. The President has also appointed Mr. Brook Taylor Kitchin to be Architect to the Local Government Board in the place of Mr. P. Gordon Smith, who has retired.

Rotary Sewage Screens.—Messrs. John Smith and Co., of Grove Works, Carshalton, Surrey, have recently supplied one of their patent rotary sewage screens to the Guildford Corporation, where it runs day and night, driven automatically by a small water-wheel, utilising the flow of sewage which is being screened. The cleaning of the travelling wire screen is also effected without attention by means of a revolving circular brush. The apparatus is at work now at several sewage farms, and is giving great satisfaction, the gratings and rakes being entirely superseded, and the sewage being freed in a more satisfactory way than before from paper, rags, &c., before going on to the bacteria beds. Even where a septic tank is used, it is found desirable to subject the sewage to a preliminary rough screening, and save the tank some of the heavier work it has to perform.

THE POWERS OF SANITARY AUTHORITIES IN REGARD TO INSANITARY HOUSE PROPERTY.

By E. Hugh Snell, M.D., B.Sc., &c., M.O.H. City of Coventry.

The extent to which a Sanitary Authority should be allowed to interfere with the rights of private property —or rather the extent to which the magistrates should be allowed to do this, for this matter under existing law is entirely in their hands and out of the hands of the Local Executive Authority—may form the subject of a variety of opinions. But when we have for the moment left out of consideration those landlords who are desirous that property owned by them and let by them to poor people shall have at least the elements of habitableness, and who are willing to effect any reasonable improvements; and when we consider the property of a different class of property-owner who will do absolutely nothing, unless compelled, in connection with his property beyond collecting the rent, we then reach a subject on which a greater unanimity of opinion will prevail, and it may be submitted that the powers at present existing for dealing with this class of property and this class of property-owner are not nearly summary enough.

The construction of new streets and houses can be properly supervised and controlled by the employment of the powers of very carefully constructed bye-laws; such particulars as the width of streets and passages, the area to be left in front of and in the rear of dwellings, the thickness and the height of walls, the size of windows, the ventilation of rooms and sub-floor spaces, and the arrangement of the drainage of houses, can all be controlled by such bye-laws; it is not possible, however, to make such bye-laws retrospective; it is clearly not possible to apply such bye-laws to old buildings; its desirability no one can question; but what is desirable is unfortunately not always feasible. It is always easy, and probably for a very long time it will be easy, for the amateur sanitarian to point to irregular, unsightly houses, to narrow streets, to still narrower courts, to small windows, to rickety chimneys, to dirty and impoverished rooms, to ill-ventilated pantries, and numerous other undesirable details; the amateur sanitarian, however, does not usually enter into details, he generally refuses to differentiate between the defects which are due to the landlord and the filth which is due to the tenant. After very mature deliberation I am prepared to submit the most unpalatable probability that although there are houses that are unfit for people to dwell in, there are also people who appear to be unfit to dwell in houses. We can compulsorily cause the landlord to cleanse houses; we cannot compulsorily cleanse people or make them cleanly in their ways.

I have myself visited houses, limewashed on an order of the Sanitary Committee six months previously, with still the marks of the bespattered limewash on the furniture, the floor and the stairs, as though the workmen had been in the day before. It may be the landlord's place to keep the walls and ceiling cleanly, it is the tenant's duty to keep the floors clean. It is one thing to see that a sufficiency of windows exist; it is quite another to open them occasionally. It is one thing to see that a fire-place and chimney exist for the proper ventilation of a bedroom; it is quite another to prevent the tenant from closing it by pasting paper over it; it is one thing to open up a pantry by an adequate ventilation opening, it is another to prevent that opening from being plugged by rags; it is one thing to provide proper water-closet accommodation outside the house, it is another to cause a tenant to empty slops and excrement until lack of utensils of various descriptions compels him to do so. Such remarks as these may apply only to the worst class of tenants, but even so, they are true—they are not fables. The problem therefore of the improvement of the houses of the poorer classes is not simply one of building new houses for them, it involves other questions as well. Of course, it is often said that if the houses were improved the habits of the tenants would improve also. This may be so. It is, however, only partially true. Habits are not simply the result of environment. There are many houses in courts in this city which on a casual examination externally appear very undesirable residences; a mere step inside, however, will show that a thrifty, cleanly tenant has made the house as clean and wholesome as any well carpeted mansion.

In expressing an opinion that a house is not fit for habitation it is not merely necessary to opine that such a house would not be allowed to be built now-a-days, it is necessary to formulate the particular points about it which actually render it unhealthy. A house cannot be condemned as unhealthy merely because it is a back-to-back house. Some large towns allow such houses to be built to-day. One has to bear in mind the standard of habitableness which is regarded as the standard of the moment. I hope a time may come when no house will be regarded as fit for human occupation which has not an accessible bath room. The day has not yet come, however, when this desideratum can be laid down as a necessity of human existence. One has to advance gradually, employing the legislative tools so far permitted by public opinion, and the laws of the land, which are presumed to express that opinion.

One further somewhat popular error in regard to this matter it is necessary to mention. It is sometimes supposed, one would gather from some speeches in public, that a Sanitary Authority can not only close houses at will, but also demolish them with a mere stroke of the pen. This is not so. It is the magistrates only who can close houses, and as for demolishing them, you can only demolish them by buying them. That is what the law on the subject practically amounts to. Large improvement schemes may accomplish much. It is, however, for your city to decide, through its representatives, how far it is prepared to go in the matter of large improvement schemes.

MUNICIPAL SANITARY INSPECTORS FOR BOMBAY.

Dr. Turner, the Health Officer of Bombay, has drawn up regulations for the examination and instruction of candidates for appointment as municipal Sanitary Inspectors. The regulations provide that the examination shall be technical, and shall be conducted by written, oral, and practical tests upon the following subjects, so far as they bear upon the duties of a Sanitary Inspector:—(1) Elementary physics and chemistry in relation to water, soil, air, and ventilation. (2) Elementary statistical methods. (3) Municipal hygiene or hygiene of communities, including prevention and abatement of nuisances, sanitary defects in and about buildings and their remedies, water supplies, sanitary appliances, drainage, refuse removal and disposal, offensive trades, disinfection, food inspection. (4) Bombay Municipal Act Statutes, and the Orders, Memoranda, and Model Bye-laws, and the Bye-laws in force in the municipality of Bombay. A syllabus of the various subjects is provided, and it is added that each candidate will be expected to report on the sanitary condition of a house and send in a plan. The books recommended for candidates are Reid's "Practical Sanitation"; Taylor's "San. Inspector's Handbook"; Corfield's "Laws of Health"; and Chapman's "Guide to Success in Sanitary Inspectors' Examinations." The recommendation of Mr. Chapman's recent book so soon after publication is a high tribute to the value of the work, and an event upon which the author is to be heartily congratulated.

WHERE THE SEPTIC TANK SYSTEM EXCELS.

The following extract from a paper on the "Purification of Sewage by Bacterial Methods," read by Dr. Leonard P. Kinnicutt, D.Sc., Professor of Chemistry, Worcester Polytechnic Institute, before the New England Waterworks Association, is striking testimony to the septic tank system of sewage treatment.

"The real practical value of the septic tank is that it destroys suspended matter without forming any very great amount of sludge or precipitate, thus having an advantage over any chemical precipitation process; that it seems to bring cellulose into at least partial solution, thus preventing the coating over of bacteria beds, either those of intermittent filtration or contact, with a layer more or less impervious to water; that it breaks up the more complex organic compounds, forming substances that are more easily acted upon by the nitrifying bacteria than the compounds in raw sewage. In a few words, it is a process which prepares the sewage for subsequent treatment on bacterial beds, either those of the double-contact system or those of the intermittent filtration system. And if I were asked what was the most important step in advance that had been made in sewage treatment during the past ten years, or since the report of the Massachusetts State Board of Health, I think I would answer, the recognition that sewage purification should, for the best results, take place in two stages, and the devising of a method, as the septic tank treatment, for breaking up the complex organic compounds and bringing a large part of the suspended matter into solution.

"Without some preliminary treatment, I feel convinced that any system for treating large quantities of sewage on limited areas, like the double-contact system—which is absolutely necessary for many cities—is doomed to failure, and I also feel convinced that with the intermittent filtration method much more satisfactory results could be obtained if the sewage first received septic treatment."

CORRESPONDENCE.

(*To the Editor of* The Sanitary Record.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

NUISANCES FROM TANYARDS.

Sir,—I have read with much interest in the *Liverpool Courier* an article dealing with your valuable observations on sanitation, and more especially local smells which constitute a nuisance, causing sickness and discomfort.

I wish to put a case before you of a nuisance through which numbers of people are made more or less ill, as probably you or your readers might be able to offer me some suggestions as to the best means of securing relief. I happen to live in a district where there is a tannery. This has been long established, and until the last few years was conducted in such a way that nothing very objectionable could be noticed. Some new process of tanning has been adopted, the nuisance arising from which is decidedly injurious to health. Ourselves, visitors, and servants suffer seriously through it, and many people around have a sad tale of woe to tell in consequence of these vile smells. A county Medical Officer of Health and his wife have just left our house, and the latter has been made seriously ill several times during her visit. Her husband has been troubled in a less degree, and considers the nuisance "atrocious."

The Local Authorities have had the matter under consideration for more than twelve months, and have done nothing. Perhaps you could tell me the best course now to take, and if you or any of your readers could give me any information as to the nature of these recent methods of tanning I should be glad. Such horrid vapours do not arise from any other tanneries that I know of, but I understand that wherever the same special and secret process is adopted similar disastrous results are experienced.—Yours faithfully,

Desideratum.

FACTORY AND HOME-MADE CLOTHING.

Sir,—I am extremely obliged to Mr. Finlay for his interesting contribution to the other side of the question. Let me say at once that personally I do not care where my clothes are made, so long as they are made by healthy workers, in properly lighted and ventilated workrooms, which are clean and in good sanitary condition. As a unit in the rapidly increasing numbers of the general public who take a keen interest in all that pertains to hygiene, I feel that the question should be dealt with. My contention is this—that all garments should be made under the personal supervision of the master tailor on his own premises, in properly constructed, ventilated, lighted, and heated workshops, which should be kept clean and in proper sanitary condition. I further suggest that special attention should be paid to such workshops by the Factory Inspectors. If my suggestion is carried out, I feel convinced there would be fewer instances of untraceable infectious cases. The only clothing factory I ever visited was the very opposite of that instanced by Mr. Finlay—everything was bright and cheerful—and the workers looked the picture of health. I trust that other readers will give you the benefit of their experience.—Yours faithfully,

J. Robinson.

London, June 8th.

Sanitary Inspectors' Associations.

NATIONAL UNION.

Arrangements are being made for the annual meeting of the National Union of Sanitary Inspectors, Midland centre, to be held at Tamworth, on Saturday next. It is proposed to pay a visit to the castle, and also, by kind permission of Mr. Kelly, to Drayton Manor. Mr. George Reid, M.D., D.P.H., Fellow of the Sanitary Institute, and County Medical Officer for Staffordshire, is President of the Union.

National Health Society.

OFFICIAL TRANSACTIONS.

It has been decided that the annual distribution of certificates, &c., shall be postponed until the autumn. It is hoped that H.R.H. Princess Christian will herself present the certificates later in the year, and it is for this reason that the meeting is postponed, it being felt that all candidates and members of the society would prefer this arrangement.

The lecturing work in the County of Monmouth has not yet ceased, application has just been received for examinations in two centres. This will practically bring the work in rural districts to a close for the season.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

NATIONAL HONOURS FOR PUBLIC HEALTH WORKERS.

THE bestowal of national honours upon public men, other than those attached to the Army, the Navy, and the Civil Service, is a question in which public health workers have a direct interest. It has long been a matter of notoriety that the guiding principle in the distribution of these honours has practically debarred public servants other than those belonging to the classes referred to from participation. From time to time, it is true, the services of literature, art, and science, not even excluding the drama, have received tardy recognition from the State. Medical science has also to a certain extent been acknowledged; but officials engaged in the administration of local government, with one or two exceptions where big reputations were concerned, have been conspicuous by their absence. It is true that a few provincial mayors have from time to time figured in the periodical honour lists; but these honours, so far from being accorded for any conspicuous ability on the part of the recipients, have been mostly the result of functions in which Royalty has played a prominent part. Some passing event, such as the laying of a foundation-stone of a Jubilee hospital by a member of the Royal Family, or the entertainment of the august visitor by the local magnate, has brought the latter into prominence, and honours have followed in due course. While we do not begrudge these gentlemen, many of whom socially and politically leave little to be desired, the titles conferred upon them, we fail to see in what respect they have a prior claim over men who have rendered valuable services to local government in an official capacity. The Borough Engineer, for instance, who by dint of years of unremitting toil, has transformed ugliness into beauty; and the Medical Officer, who has kept disease at bay—surely these should not be forgotten. The Public Health service is assuredly not the least among local administrative bodies, nor is the work its officers perform among the least important of the various links that go to form the chain of our national prosperity. And while we place special emphasis upon this particular branch of local government as being the one in which we are naturally most interested, we do not blind our eyes to the fact that in other branches the same argument holds good. There are hundreds of men engaged in Council and Poor Law work whose services to the State cannot be over-estimated. Some of them have given such services gratuitously, and the least that a Government could do, one would think, would be to express its gratitude in the manner suggested. A perusal of the lists of honours issued from time to time reveals the very patent fact that back-stair influence in this direction has accomplished more than actual merit; the modest man has been brushed aside, while the man with a "friend at Court," and frequently little else to recommend him, has stepped in and secured the coveted prize. Up to very recently those whose claims we are putting forward appear to have lacked an advocate, but Mr. Thomas Farrow, the able editor of our contemporary the *Councillor and Guardian*, has stepped into the breach. Convinced of the necessity of someone moving in the matter, he recently called the attention of the Right Hon. Walter Long, M.P., President of the Local Government Board, to the facts, and has, we are glad to announce, secured a definite promise from him that the suggestion should receive every consideration. Thus encouraged, Mr. Farrow went a step further, and submitted a list of typical public men whom he considered ought to be "in the running" for national honours. Needless to say, we at once assured Mr. Farrow of our desire to co-operate with

him, and he has signified his appreciation of the same in a very cordial manner. In the meantime we should be glad to have the views of our readers upon the subject. We feel convinced that a strenuous advocacy is all that is needed to bring about the desired results.

British Dairy Farmers in Congress.

The annual Congress of the British Dairy Farmers' Association was held this year in Scotland, the chief centres visited being Kilmarnock, Glasgow, and Edinburgh. The delegates seem to have had both a pleasant and a profitable time. From the reports of the proceedings two points emerge with special prominence—the proposed legal standard for milk, and the question of the pasteurisation of milk. The first of these points was the subject of considerable comment at the closing dinner, and the opinion of all those who referred to the matter was that the adoption of a fixed standard of 3¼, or even 3 per cent. would be found to be impracticable. Mr. George Barham, London, humorously remarked that if the proposed standard were to become law he feared that he and many others of those present would be unable to attend that year's Conference, as they would probably be doing their six months in prison! Another speaker, in the same strain, expressed his conviction that the fixing of a 3 per cent. standard would result in nine-tenths of the distributors of milk being brought into court within a year; and another, that the law could not make possible what science and practice had hitherto failed to make possible. Similarly, Dr. Drinkwater, Analyst to the Edinburgh Dairykeepers' Association, gave it as his opinion that the question of the milk standard would settle itself, for if they passed an impossible law it would simply fall into abeyance. These, it will be observed, are the views not of dishonest farmers or dealers who are only anxious to shield themselves, but of those who represent the most enlightened and advanced opinion connected with the trade, and whose chief desire is to maintain the purity of our milk supply, and as such they deserve the fullest consideration. The other matter, the question of the pasteurisation of milk, formed the subject of an interesting paper and discussion at one of the meetings. Mr. James Stirling, Glasgow, who read the paper, described the various processes minutely—first, the method adopted in Denmark, by heating the milk to 185 deg. Fah., and cooling it immediately to a temperature of about 50 deg., together with the use of a pure lactic ferment, to start the ripening of the cream. To obviate the distinctly cooked flavour which the milk acquires by this process, another method has, however, been adopted—by retaining the milk at a temperature of 160 deg. Fah. for twenty minutes before cooling it down. Mr. John Speir, Newton, who was, if we recollect aright, one of the members of the Royal Commission on Tuberculosis, said that he was old-fashioned enough not to believe in these methods; for if attention was directed to securing proper conditions at the source of supply, they would so far reduce the risk of contamination as to render pasteurisation unnecessary. The general opinion seemed, however, to be that this was a counsel of perfection, and that the danger of contamination in the dairy, through the germ-laden atmosphere of the byres, and the other conditions under which cows are milked was so great, that it was practically impossible to keep the milk pure until it was delivered to the public without recourse to pasteurisation, which was the only absolutely safe plan; and further, it would be found by the dairyman to pay more than by the use of antiseptics. Otherwise it would be hopeless to expect dairymen to adopt it.

What is Pure Sugar?

A decision of considerable importance under the Food and Drugs Acts was pronounced in the Sheriff Court of Edinburgh last week in a case against the Home and Colonial Stores, Limited. There was no dispute as to the facts. An Inspector under the Acts went into the shop and asked for a pound of sugar at a penny. He was told that owing to the new tax the sugar formerly sold at a penny per pound was now sold at 2½d. for two pounds. He took two pounds, and the sugar on analysis was found to contain 2·24 per cent. of mineral matter, chiefly potash salts, and 3·76 per cent. of water. On these grounds the seller was charged with having sold an "article not of the nature, substance, and quality of the article demanded." The analysts for the prosecution maintained that there was no necessity for the presence of these ingredients in pure sugar, and they could have been got rid of by proper refining. It was not, however, alleged that they were foreign to the sugar, *i.e.*, that they had been introduced. They were native to the sugar, and the removal of the impurities and the production of pure sugar was only a question of extra trouble and extra expense. Among the witnesses for the defence were chemists and analysts of repute, and two sugar refiners, who stated that absolutely pure sugar was unknown in the commercial world. They denied that there was any recognised standard of purity; it varied according to price. The alleged offence appears, therefore, to have consisted not in adulteration, such as the addition of sand, for a fraudulent purpose, which is what the Food and Drugs Acts are aimed at, but in not having rendered the sugar sufficiently pure. The real questions in the case accordingly came to be—"What is sugar?" or, rather, "What is sugar at 1¼d. per pound?" and was the Inspector supplied with the article he asked for? The prosecutor contended that sugar containing 99·5 per cent. of sucrose was a well-known article in the trade, and that when a purchaser demanded "sugar," it was pure sugar that he should get. The Sheriff, in giving judgment, held that this proposition could not be maintained, and that the Inspector had got what he had asked for. He asked not simply for "sugar," but for sugar at a certain price, and he got the article sold throughout the trade at that price. That being

so, he could not be held to have been "prejudiced" by the sale. It was established by the evidence that the word sugar was a wholly indefinite expression, and that sugar of at least four kinds were known in the sugar trade. The argument that the purchaser demanding sugar at 1¼d. per pound must get pure sugar was met by conclusive proof that pure sugar containing 99·5 per cent. of sucrose would be quite unsuitable for the purposes for which the cheaper sugar was bought. The cheaper sugar was very soluble, and was largely used in cooking and for eating with fruit, while "pure sugar" was not necessary for those purposes. The article asked for by the Inspector was ordered at its trade price, and had been supplied at the trade quality and the trade price. Nothing had been added to it for any purpose whatever, and all its qualities were native to the article. It was a perfectly wholesome article of food, and there was not the slightest suggestion of unfairness in the transaction. The complaint was therefore dismissed.

The United States and Tuberculosis

The Treasury Department of the United States has taken a firm line in dealing with tuberculosis. It has directed the immigration officials to consider tuberculosis as a dangerous and contagious disease, and the consequence will be that no more consumptive immigrants will be received in the country. The order will operate in bringing about a large decrease in immigration, but it will not stop there, for it will probably also affect the cabin passenger traffic. The step is a strong one to take, but with the now-received conceptions of tuberculosis it is perfectly defensible as a measure of self-protection. Will this country not have the courage to adopt similar measures for the protection of its population? We have strict regulations regarding cattle diseases, but where humanity is concerned, at least in the matter of tuberculosis, we allow complete liberty and freedom from restraint. And yet a very large proportion of our pauper immigrants must bring with them the seeds of this disease.

A Midland Sewage Scandal.

It is impossible to describe otherwise than a scandal the state of things revealed at the last meeting of the Newcastle-under-Lyme Town Council. The Medical Officer of Health reported that a most serious and continuous nuisance existed in consequence of the pollution of the Lyme brook by the Silverdale Local Authority. In substantiation of this charge, he stated that he found that practically the whole of the Silverdale sewage was turned into the Lyme brook in a crude state, without any real attempt at treatment being made. At one point the outfall sewer was fractured, and quite one-half of the contents (crude sewage) passed direct into the watercourse. In another place the pipe conveying the sewage from a small hamlet was fractured just where it crossed the stream, and the sewage flowed into the Lyme. He admitted there was some evidence of irrigation, but the thing was badly done because of the lack of any method in the work. He had tested the effluent and found that it was practically the same as crude sewage, "showing that irrigation alone was useless." It hardly seems possible that such a condition of things can exist. But we cannot understand why it has reached the present scandalous state. Such things do not come about in a day, and the Newcastle Town Council cannot be wholly exonerated from blame. The broken pipe and the defective outfall should have been remedied long ago. But, of course, the chief blame must be fixed upon the Silverdale Authority, which seems to be utterly oblivious to the dangers of its neglect. One of the Newcastle aldermen urged that proceedings should be taken against the offending Authority, but the prevailing opinion was that a warning would be sufficient. It may be, but we think there would be fewer such cases if action was taken occasionally. The idea of leniency is traded upon, and the day of reformation is indefinitely postponed.

Bootle's Medical Officer.

We are always glad to see Sanitary Authorities appointing whole-time officers, but when this is done adequate remuneration should be given for their services. When a small salary is offered, and we are told that a "thoroughly competent man" can be obtained for it, there is always the idea present that a place is being made for some one. Thus, last week the Bootle Town Council discussed the appointment of a successor to the late Dr. R. J. Sprakeling. Some of the members appeared to think that a salary of £350 per year was sufficient to pay a gentleman to act as Medical Officer of Health, visiting Medical Officer of the Linacre Fever Hospital, and surgeon to the police force and fire brigade. The one appointed is to give his whole time to these offices and be debarred from taking private practice. Now, even if it was the medical officership alone that was vacant, the amount is not sufficient for the post. Bootle is a town with over 60,000 inhabitants, and it is growing continuously. The £350 does not work out at £6 per 1000 inhabitants, which is considerably less than that paid by most Authorities for "part timers." Of course it is possible that someone with a private income is going to apply for the post, as one of the things said by the chairman of the Health Committee was that, although the salary was small, "he was informed that they would get a gentleman applying for the position who would be a credit to the borough." We contend that no public appointment should be made upon such an understanding. The conditions of all appointments should be settled on the qualifications and competency required in their occupants, and no other consideration should be allowed to prevail. We want the *best* men for the public health service, and such salaries should be paid as to attract the most competent, and not merely those who desire to supplement an already assured income.

Hospital Sunday.

Next Sunday the inhabitants of the great metropolis will have another opportunity of showing a practical sympathy with the many institutions which exist for combating disease in their city. The need of funds to carry on the work is greater than ever. It is painful to watch the advertisements in the daily papers pleading, almost piteously, for help, in order that hospitals and kindred institutions may continue their work. We agree with our contemporary the *Hospital*, that "our great London hospitals are not supported either by the patients who are so ready to avail themselves of the benefits to be obtained, or even by those who subscribe to them, but are in reality supported up to one-half of their total receipts by the charity of those who have gone before." In 1899—the last year for which complete statistics are available—nearly one million and three-quarter patients were treated in the voluntary hospitals and dispensaries of the metropolis. Their total income for the same period was £1,097,776. With but comparatively little more support, the work of these excellent institutions might be increased 50 per cent. In many of them beds, and even whole wards, are unoccupied for the lack of funds. "Year by year the number of the sick poor to be cared for must of necessity increase, and unless a sustained effort is made to meet the demands, Londoners will have to smart under the reproach of being so careless, so selfish, as to grudge giving adequate help to our suffering and less prosperous brethren. To plead inability is, in nine cases out of ten, mere dishonesty. We can all do something." Let the first Hospital Sunday of the new century mark an epoch in the history of the Fund. London was never richer than it is to-day—let its generous gift in a good cause never be greater.

Sydney's Annual Report.

We have received a brief synopsis of the annual report of Dr. Armstrong, Medical Officer of Health for Sydney, N.S.W. It contains one or two points calling for special mention. First, it records a departure in the engagement of health officials. These are still subject to the municipality, but the Government has the right of veto as to their dismissal. This, says the Doctor, "was a novelty so far as Australian municipalities were concerned, though it had been tried in Great Britain and elsewhere with successful results. The object was to render Sanitary Inspectors more independent than they otherwise would be—independent especially of the influences which occasionally intrude into municipal bodies. So far, the experiment had proved an undoubted success in Sydney. The men had been engaged on the strength of their qualifications alone, and this had been the only consideration allowed to prevail in the process of selection. The Inspectors appointed had all undergone a systematic course of instruction in sanitary matters, and had received certificates as to competence. The chief Inspector was a civil engineer of great experience, who, since his appointment, had repeatedly proved his value." This is only what was to be expected—when men are appointed to office on their merits, there is sure to be an improvement in the sanitary administration of any district. Another special matter mentioned is that a system of house-to-house inspection has been instituted, and with it the card system, under which every house possessing sanitary defects has a card to itself. On this are inscribed its character and sanitary history—the cases of sickness that have occurred there, and the deaths. Under the old style, separate entries were made from day to day, and, in hunting up records, much depended on the memories of the officials. These entries are still made, as they have been found useful, but absolute reliance is not placed upon them. To add to the value of the new system, information is daily received from the Registrar-General's Department as to the deaths in the city, and this has now become a matter of routine. With a more vigorous and watchful administration improvement has taken place in the health of the city, zymotic disease has decreased, and there is a decreasing death-rate.

Do Municipal Works Pay?

There are many critics who delight in denouncing "municipal trading," and who would have the people believe that it would be much better to leave all such things to private enterprise. But there are some hard facts to get over before they will ever convince the public that their criticisms are right. Here, for instance, is the record for last year of the municipal works of Sheffield. Until a comparatively recent date the Corporation possessed no source of revenue but the rates. It has now acquired the water undertaking, the tramways, and the electric lighting of the city. In 1863, during the existence of the Sheffield Water Company, the bursting of Bradfield reservoir was followed by an increase of 25 per cent. in the water charges. Last year, after the water undertaking had been absorbed by the Corporation, 12½ per cent. of this increased charge was remitted; but, notwithstanding this, a profit resulted on the working of £17,000. This year the net profit has increased to £25,400. The taking over of the tramways has been an equally successful venture. For the year 1899-1900 the number of passengers carried was over 19 millions, and during the twelve months just closed the total has risen to 34 millions, or very nearly double. The gross profit earned during the past year has been £48,657 6s. 10d., and, after the deduction of the sums necessary for interest, sinking fund, and maintenance, the net profit is still the handsome sum of £21,817 17s. 2d. Handicapped as they are with the burden of borrowed capital, the tramways since they came into the city's possession in 1896 have earned a total net profit of £64,624 10s. 2d., of which £22,000 has gone in the relief of the rates. If the electric light undertaking cannot furnish quite so satisfactory a result, it must be understood that it started under a severe handicap. The price paid to the old company was a very high one, and the charges for sinking fund and interest correspondingly heavy. The

balance-sheet this year shows a gross profit of £24,953 9s. 0½d., and the net balance is £4048 13s. 10½d. During the ensuing year the Corporation expect to make little, if any, profit out of the electric light, owing to the large amount of unproductive expenditure which a contemplated alteration in the system will involve. A net profit of £50,000 for one year will take a lot of explaining away, and proving that municipal trading does not pay.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

The Municipal Officers' Association, which was started a few years ago with the following points for its programme, viz.:—"To bring Municipal Officers into direct association with one another, and generally to promote their interests; to secure adequate superannuation for Officers of Local Authorities; to encourage the study of and to arrange opportunities for the discussion of Local Government questions, and of any judicial decisions and proposed legislation relating to such questions," is making good headway, more especially in the South of England, and I venture to assert that before many years it will exercise a very powerful influence for the protection of Municipal Officers and for the promotion of unity of action on Local Government questions.

Such an Association should be supported by all public officials, for by co-operation their mutual interests can be advanced, and the more numerous its members are the greater will be its sphere of action. The annual subscription, it may be observed, is only 5s. per annum, which covers payment for a copy of the monthly organ of the Association, the *Municipal Officers' Journal*, and the only qualifications for membership are that candidates must be officers duly elected by a statutory Local Government Authority. The president of the Association for the current year is Mr. G. Laurence Gomme, the Clerk of the London County Council, and the secretary is Mr. Frank G. Beeching, 117, Holborn, London, E.C.

The Royal Institute of Public Health, who are holding their annual Congress at Eastbourne from July 25th to 30th, have issued their provisional programme, and a most interesting one it is. Members and delegates will find that ample provision has been made for their enjoyment in the way of receptions, garden parties, excursions, concerts, and balls. It has been hinted that these Congresses of the Institute of Public Health are more renowned as sources of conviviality and gaiety than for the business which is transacted there, and it is to be hoped that on this occasion more genuine interest will be taken in the papers and discussions than has been the case in recent years.

There will be, as usual, a Municipal Engineering Section at the Congress. Somehow in the past Municipal Engineers have held aloof from active participation with the work of this Institute, the opinion being generally held that these Congresses were run by and for the medical profession. Mr. Chas. H. Lowe, M. Inst. C.E., is to be the president of the Engineers' Congress. Applications are being sent out to Municipal Engineers by the hon. secretaries for the contribution of papers. By the way, the literary character of this circular is not such an example of English as is to be commended. "It is requested," so the application reads, "that papers should, if possible, be sent in to the undersigned not later than July 1st next, or if this is not possible, the title of the paper;" and "papers should take a maximum of from fifteen to twenty minutes to read, although in special cases this would be no fixed rule." Possibly the person who drafted this circular knows what he intended to convey. It is doubtful whether most readers will.

One comes across many so-called "experts" in connection with the various phases of municipal engineering, but I venture to believe that the particular individual, whose report appears in this week's issue, who for evident reasons prepared a report on certain sewage disposal systems without being commissioned by any authority, or person or persons to do so, and, forthwith, secures its insertion in a provincial paper, circulating in a town where a system—opposed to that in which he is, I conjecture, interested—is being promulgated by the Local Authority, is, I am bound to say from a wide knowledge of the idiosyncrasies of this type of "expert," an expert in the art of pushing of his own nostrums.

Now one has a genuine regard for any patentees or firms who push the sale of their own specialities in genuine British fashion, but when these abuse the privilege of the Press, to anonymously attack other systems—as one only too frequently sees it in provincial papers—a community is juggled and blinded, and the difficulties of Local Authorities are increased, whilst huge sums of money are too often wasted through improper schemes being foisted upon a district by individuals who work upon the ignorance of representatives and ratepayers.

I venture to think that neither an engineer nor a chemist of any repute, whether he style himself an "expert" or not, would risk his reputation by contributing such a communication as the one in question to this or any other professional journal of standing over his own name. The *bonâ fides* of this "expert" are, of course, valueless. That sewage can be efficiently purified, and practically without sludge, by any one of the numerous systems of bacterial and biological treatment, no intelligent engineer or chemist will venture to deny. It is a matter for serious condemnation that most of the sewage works which have been designed within the last four years have been converted into bacterial and biological systems, whilst the costly machinery for the pressing of sludge now represents wasted money, and can only be disposed of as scrap iron.

Briefly, the assertions of the "Expert" in question are as follows:—(1) The result of experiments conducted at London, Leicester, Leeds, and Manchester, to test the efficiency of the bacterial system of sewage purification, has been completely falsified. (2) The theory of the system is not admitted by the officials of the Local Government Board to be practicable. (3) That filters are completely choked in one and a-half years, even with a domestic sewage like that of London. (4) That the double or multiple contact-bed system "*without previous tanks*, is regarded as *dead*."

Now I have no hesitation in observing that these assertions are in every case *absolutely untrue*. I have frequently pointed out in these columns that no engineer or chemist is justified in dogmatising as to the treatment of sewage, and saying that any one system is applicable to the purification of the sewage of all towns and places, and I am convinced that no system has yet been discovered which can be guaranteed to

answer such conditions. On the other hand, there is no justification for any individual who, to further the adoption of a system to which he is "wedded" for particular reasons, publishes statements regarding a competing system or systems which as in this case are entirely at variance with fact. This line of conduct may temporarily mislead, as such a letter is doubtless intended to mislead, the readers of provincial papers where it appears, when a sewage scheme is being propounded in a district, but to impartial-minded engineers and chemists such men are not "experts," but belong to the class known as "charlatans." Perhaps "Expert" will be good enough to give his views in the columns of this journal and controvert me. They will be, I doubt not, welcome. SENEX.

LADY SANITARY INSPECTORS.

AMUSING DISCUSSION AT DUNDEE.

SHOULD Sanitary Inspectors of the gentler sex be known as "Lady Sanitary Inspectors," "Female Family Advisers," or "Women Inspectors?" These were questions considered at the last monthly meeting of the Dundee Town Council.

The discussion took place on the recommendation of the Sanitary Committee that the appointment of two lady Sanitary Inspectors should be delayed.

Councillor ELLIOTT supported the Committee's suggestion on the ground that there were so many changes going on, or about due, in the Sanitary Department; it was the most advisable course to let the matter lie over. Once they had everything in order they wanted, they could consider the proposal.

Treasurer RITCHIE championed the cause of the lady Inspectors, and moved the Committee be instructed to take up the question at once. Wherever lady Inspectors had been appointed they had, he said, been of great value.

Bailie BARRIE seconded, on the grounds that the "health is the wealth" of the town.

Mr. ELLIOTT then moved the approval of the minute.

Bailie CRICHTON, and Mr. DOIG were of opinion that the Inspectors would do a vast amount of good in teaching poor people to keep their houses clean. They would, too, instruct mothers how to feed their children, which in Dundee, with its high infantile mortality, was a great consideration.

Mr. HENDERSON pointed out that in other towns the female inspectors were known by the title of "female family advisers," because the chief part of their duties was to visit poor homes and instruct mothers in cleanliness and in the upbringing of children.

Mr. JOHN ROBERTSON was in great form over the threatened appointment. What good, he asked, would the citizens receive from two women gossiping from door to door, which would be the chief part of their occupation? Were they going to pay these inspectors to teach mothers how to feed their children, was it to be part of their work to clothe the naked? He was afraid that if the Inspectors went into a house to instruct a woman how to wash the floor, they would soon find themselves at the bottom of the stair. (Laughter.) If they wanted female Inspectors, they must have a female department. It simply meant a reorganisation of the whole sanitary staff.

Notwithstanding Mr. Robertson's forcible illustration, the Council resolved, by fourteen votes to twelve, to instruct the Sanitary Committee to at once report on the appointment of "lady Sanitary Inspectors," or "female family advisers."

Public Works.

SEWERAGE.

AT a recent meeting of the Rhymney District Council tenders were accepted in connection with the sewerage scheme, and it is hoped to commence the work in a fortnight.

THE North Darley Urban District Council has instructed Mr. Harry W. Taylor, A.M.I.C.E., of Newcastle-on-Tyne and Birmingham, to prepare a scheme of sewerage and sewage disposal for its district.

THE Streets Committee of the Walsall Town Council recommends that a 24in. main outfall sewer be constructed through the Arboretum, from Buchanan-road to Lichfield-street, at an estimated cost of £1000, and that application be made to the Local Government Board for sanction to a loan to defray the cost of the work.

THE Nuneaton and Chilvers Coton Urban District Council has given an order for a Meldrum Simplex destructor to be erected at the sewage works, to supply all power for pumping, &c. Similar plant has been working at the Hereford sewage works for four years, resulting in a saving of from £400 to £500 per annum.

MR. R. H. BICKNELL, an Inspector of the Local Government Board, has just held an inquiry into the application of the Castle Ward Rural District Council to borrow £2000 for works of sewerage and sewage disposal for Dinnington Colliery. The sewage will gravitate to the outfall and be disposed of bacterially. Mr. Harry W. Taylor, A.M.I.C.E, of Newcastle-on-Tyne and Birmingham, is the engineer. There was no opposition.

THE Local Government Board has refused the application of the Branksome Council for leave to borrow money for the sewerage scheme—a scheme which, it will be remembered, proposed to deal with the sewerage of part of the district on the "septic tank" system, and to discharge the effluent into the Bourne Brook. The Bournemouth Corporation opposed on the ground that, even if the effluent were absolutely pure and innocuous, there were strong sentimental objection to sending it through the Pleasure Gardens intersecting the centre of a popular health resort. The Branksome Council has still to face the problem of how to meet the sanitary requirements of a part of its district, which is exceptionally difficult to deal with.

THE lease of a sewage farm of the Wolstanton Rural District Council having expired, negotiations have been going on for the purchase of the same, and the question of price was referred to arbitration. Consequently an arbitration was held at the North Stafford Hotel, Stoke, last Thursday, to fix the price. Mr. Frederick Fowler (Sheffield) sat as umpire, with two arbitrators. Mr. Freeman, for the owners, pointed out that the land had a special value as accommodation land and a remote value as building land. The total value of the minerals —including some lesser seams—with 10 per cent. added for compulsory purchase he put at £27,196. This with the surface value made a total of £41,400 for the site of the sewage farm. He asked Mr. Udall if he would negotiate on the basis of the Local Authority, merely purchasing the surface rights. Eventually it was agreed that the surface price of the land should be £10,000—subject to the confirmation of the Council—the Council to pay £520 for the cost of the arbitration, agreement, action, conveyance, and umpire's, arbitrators', and counsel's fees. The Council to pay its own costs and counsel's fees and witnesses. The arbitration stood adjourned that the arbitrators might give a formal award when the Council shall have sanctioned the purchase.

A Local Government Board inquiry has been held at Littleborough with reference to the application of the Urban District Council for sanction to the borrowing of £13,400 for works of private street improvements, and £1440 for works of sewerage, and £375 for the diversion and covering of a watercourse.

It has been recognised for a long time, says the *Lancet*, that a main sewer to deal with a portion of the sewage in the lower part of Swansea is urgently needed, and various schemes have from time to time been discussed by the Corporation. These have at length been focussed into three definite proposals, in one of which the outfall is in the town at the pier-head and in the other two at Brynmill, a short distance from the more densely-populated portion of the town but quite close to the sands and promenade. The outfall at the pier-head and in one of the Brynmill schemes discharges the sewage into the sea untreated, but in the alternative Brynmill scheme it is proposed to provide for a septic tank between the termination of the sewer and its outfall, though the effluent is not to be subjected to any filtering process or to be made to pass over land. The members of the Town Council have been very evenly divided in their opinions as to the merits of these three projects, the cost of which does not vary more than a few thousand pounds, for the engineer's estimate in each case is between £70,000 and £80,000. In spite of the advice of its responsible officers, the Town Council has decided by twenty votes to eleven to carry the sewer to Brynmill and to discharge the sewage after it has passed through a septic tank on to the sands at low water. There still remains the Engineering Inspector of the Local Government Board to be reckoned with, and hitherto the policy of the Board has been to require provision to be made for the treatment of the effluent from a septic tank before sanctioning expenditure upon works of this nature, though it is possible that there may be in the local conditions at Swansea circumstances warranting a departure from this policy.

At the last monthly meeting of the Sowerby Bridge District Council, the question of the new sewage scheme was brought forward. The Local Government Board wrote to the effect that it was not prepared to sanction the proposed works of sewage disposal, as it was advised that they were inadequate to meet the requirements of the case. The usual requirements in such cases were (1) that the water-holding capacity of the coarse and also the fine beds when matured should be equal to one day's dry weather flow; (2) that the sewage, after passing through both coarse and fine beds, should be subjected to further treatment on an area of suitable land in the proportion of not less than one acre to every thousand persons draining to the outfall; (3) that provision should be made in the scheme for dealing with excess liquid beyond three times, but not exceeding six times, the dry weather flow, either by distributing it on a special area of land prepared for the purpose, or by passing it through separate storm-water filters of sufficient extent to admit of a rate of filtration not exceeding 500 gallons per square yard per diem. The Board further required the Council to ascertain approximately, if not exactly, the volume of the dry-weather flow from the parts of Sowerby and Norland which would be drained into their sewage system. The engineer was instructed to again make observations with a view to ascertaining the dry-weather flow. The Sowerby District Council stated that approximately the dry-weather flow from its part of the district would be 70,000 gallons per day. It was decided not to alter the original scheme by taking in trade effluents. The Clerk was instructed to write to the Town Clerk of Halifax, pointing out that a considerable amount of sewage was going into the Sowerby Bridge district from Cote Hill and Bairstow, and requesting the Corporation to take steps to abate it.

Last week a Local Government Board inquiry was held at Alvaston, near Derby, in reference to an application from the Urban Council to borrow £12,000 for a scheme of sewerage. Mr. Stone, of Derby, supported the application, whilst Mr. Bostock opposed it on behalf of several members of the Council. The inquiry was protracted.

A scheme of main sewerage and sewage disposal prepared by Messrs. D. Balfour and Son of London, and Newcastle-on-Tyne, has been approved for Wiseton, Doncaster, and an immediate start is to be made with the work. The method of sewage disposal consists in the treatment in self-acting bacterial tanks, the effluent from which will discharge into the adjoining watercourse.

As the result of the recent extension of the Ripon city boundaries the Corporation made application at a Local Government Board inquiry held last week before Mr. W. O. E. Meade King, for sanction to borrow £5000 for purposes of sewerage and sewage disposal, and £3000 for carrying out certain street improvements. It appeared from the statement made by the Town Clerk (Mr. M. Kirkley) that the three portions added to the city through the extension contained 210 acres, and were at present unprovided with sewerage or sewage disposal works The population of Ripon in 1891 was 7512, and according to figures which he had received from the Census-office, which were subject to revision, in 1901 the population was 8225. This was a total increase for the whole city of 713; but of these 343 were brought in through the extension, the increase in the added part of the city being 89, and in the city before the extension 281. The city was assessed at £32,552 for district rate purposes, and the outstanding debt under Public Health Acts was £30,531. There was no opposition, and the proceedings closed with a vote of thanks to the Inspector.

WATER.

Mr. H. P. Boulnois, C.E., held an inquiry on behalf of the Local Government Board at Bagillt last week with reference to the application of the Holywell Rural District Council for sanction to borrow the sum of £2500 for purposes of water supply in the Bagillt special drainage district.

At last week's meeting of the Otley District Council an account for £1450 was passed to be paid to Mr. M. D'Wyvill, Denton Park, for easements for three miles of water mains through his land. The question of compensation has been in the hands of Mr. Straughan, C.E., on behalf of the Otley District Council, and Mr. Routh, C.E., acting for Mr. Wyvill, who referred the matter to Mr. Crowther, C.E,, as umpire. The price was considered by the Council to be satisfactory.

At last week's meeting of the Waterworks Committee of the Manchester Corporation, the fourth and final contract was let for the supply of iron pipes for the second pipe from Thirlmere to Manchester. The contract is for the supply of 15,750 tons of castings, which are to be placed between Grasmere and a point near Kendal. The total weight of metal included in the four contracts is 62,700 tons, and the price, it is estimated, will be about £314,000. When the consent of the City Council to the laying of the second pipe was given, a year or so ago, the price of iron was high as compared with the present market rate. It is calculated that by waiting, and thus having advantage of the drops in the iron market, the Committee have placed their orders in such a way as to effect a saving of nearly £80,000, a fact upon which the members congratulate themselves. The reckoning is based on prices which they had to pay for some urgently necessary pipes for the Longdendale works whilst high values prevailed. No contracts for laying the Thirlmere pipes have yet been entered into.

The Ilkeston and Heanor Water Board Bill came last week before the House of Lords' examiner for proof of compliance with Standing Orders. The objects of the Bill are to constitute a joint board representative of the Corporation of Ilkeston and the Heanor Urban District Council, with power to acquire the undertaking of the Meerbrook Sough Company, and to construct works for intercepting and distributing the waters of the Meerbrook Sough, and for other purposes. The Standing Orders having been found duly complied with, the Bill will be reported for second reading.

At a recent meeting of the Llanelly Waterworks Committee the chairman (Mr. Ernest Trubshaw) reported excellent progress with the new reservoir which Mr. L. P. Nott is constructing at Upper Lliedi. This will have a storage capacity of 200 million gallons, and with the existing reservoir at Cwmlliedi holding 220 million gallons, will place the town in possession of a magnificent water supply. Mr. Trubshaw remarked that the cost of the works would be well within the amount borrowed, and, in all probability, when the contract was completed, they would have £4000 or even more in hand. It had been decided to pitch the sides of the new reservoir.

The scheme for augmenting the water supply of the city of St. Andrews, which was commenced two years ago, has now been completed. Prior to this year there was only storage capacity for a reserve of water to tide over a dry season of three million gallons, but a new reservoir has been constructed in Langraw Den, which will augment the storage water to seventeen million gallons, and it is calculated that there is now amply sufficient along with the dry weather flow of the various streams, to provide forty gallons per head of the population daily throughout the whole of the summer months. New filters have also been built at an elevation of 70ft. higher than the filters previously in use, and this will give a much needed additional pressure to the higher parts of the city. The engineers were Messrs. Belfrage and Carfrae, Edinburgh.

The building of a new reservoir contiguous to the present reservoir at Littledenny, and the extension of the Faughlan reservoir at Carron Bridge, Denny, at an estimated expenditure of about £100,000, was begun last week at Windyedge and Drumbowie, the site of the new reservoir. There was no elaborate function at the cutting of the first sod. Mr. Copland, Glasgow, is engineer to the trust, and Mr. John Best, Edinburgh, is contractor. The start was made in the presence of Mr. Pirrie, representative of the engineer; Mr. Finlay Best, Mr. Shand, C.E., for the contractors; Mr. Main, Mr. Wm. Murray, manager, for the contractors; and Mr. Massie, superintendent of Falkirk and Larbert Trust. The cutting of the first sod was entrusted to Mr. Pirrie, who performed the ceremony amid cheers, wishing success to the undertaking. The whole work is to be completed in two years.

At the last monthly meeting of the Richmond Rural Council, Mr. Dent referring to the Newsham water supply, said they did not agree to the scheme suggested by the Local Government Board, and were in favour of abandoning it altogether. Mr. S. Johnson objected to such a course being taken, and pointed out that a large sum of money had already been spent in preparing plans, &c., and if it was abandoned these expenses would have to be paid by the whole of the district. In view of this work, it was thought advisable for some of the outside farmers to be elected on the Newsham Parochial Committee, and Messrs. Glover and Shippon were accordingly elected. A letter was read from Newsham stating that at a special meeting of the ratepayers the water supply question was discussed, and the sinking of two wells, the erection of two pumps, and boring for water at the top of the hill were suggested. It was decided to try the last-named suggestion.

The Corporation of Accrington has resolved to spend a further £9000 in electric mains and other electric lighting works, and £1000 for the acquisition of a site for baths and washhouses.

The members of the Lancaster Corporation paid their annual visit of inspection to the waterworks in the Wyresdale district last week. The new reservoir at Blea Tarn has just been completed, and will be formally "tapped" shortly. The sum spent on its construction is £50,000, £10,000 less than borrowing powers were obtained for. The capacity of the reservoir is 120,000,000 gallons.

LIGHTING.

The Wigton Urban District Council contemplates buying the gasworks of that town, the property of the Wigton Gas Company, Limited.

The tender of Messrs. R. F. Hislop, at £1232, for the construction of a regenerative retort bench at the Clacton Gasworks, has been accepted by the Urban Council.

A Local Government Board inquiry has been held at Bangor regarding the application of the Urban Council for a loan of £4169 for the purpose of carrying out gas extension works.

The work in connection with the installation of the electric light at Ambleside, which has been so long delayed, is now being vigorously pushed forward, and the main thoroughfare is now the scene of active operations. Where connection has been made and the lights tested it has been found highly satisfactory.

At the last monthly meeting of the Chorley Town Council, the Town Clerk submitted a letter from the Local Government Board sanctioning a loan of £21,300 for electric lighting purposes. It was resolved to interview the Lancashire Electric Power Company, and, if possible, obtain terms for a supply of electricity in bulk.

The Shoreditch Borough Council has decided upon expending a further £10,000 in extending its electric lighting mains, and has also put the official seal to an agreement to purchase certain freeholds in the neighbourhood of Haggerston Station, North London Railway, for the erection of municipal dwellings. The agreed price is £24,000.

During the seventeen years the Coventry gasworks have been in the hands of the Corporation there has each year, with only one or two exceptions, been a considerable sum of money handed over in reduction of rates; but the accounts for the past twelve months state that while the working profit was £9955, the final profit is only £329, which is recommended to be carried forward to the next account.

The directors of the Enfield Gas Company are offering for sale £5000 of Consolidated Ordinary Stock of the company. There are but very few gas companies, we believe, which have the power to offer new issues of capital, to other than the existing proprietors, at a fixed price. The South Metropolitan Gas Company is one of the exceptions, and the Enfield company another. Both obtained, on their own initiative, powers from Parliament to give the consumers of their gas a preferential standing in this respect; and to our thinking it is a wise as well as equitable arrangement to place the consumers in a better position in regard to the issue than the Stock Exchange or the man from New York. We imagine the consumers in Enfield will appreciate this consideration as much as those in South London have done, in which case applicants for allotments will doubtless have to be content with a considerably smaller amount of stock than they apply for.

The Alfreton Gas Bill has been read a third time in the House of Commons.

Last Friday afternoon Colonel Crawford, J.P., chairman of the Walker and Wallsend Union Gas Company, opened the valve which connects the works with the new Gadd and Mason gasholder, which has just been completed. The structure has a capacity of 300,000 cubic feet, and the work has been carried out in the remarkably short space of three months by Mr. D. M. Brims, of Newcastle, and by Messrs. R. and J. Dempster, Limited, of Manchester.

At the last monthly meeting of Linlithgow Town Council, a communication was read from Messrs. Crompton and Co., electrical engineers, London, inquiring what had been done by the Council in regard to their offer to introduce the electric light to their town, and offering to apply for a Provisional Order in their own name. The letter was remitted to the Lighting Committee, which is to submit a report of the whole question to an early meeting of the Town Council.

At a meeting of Dumfries Town Council last week the Electric Light Committee reported that it had found it impracticable to proceed with the scheme of utilising water power for generation of electric lighting according to the report of Mr. Ritchie, electrical engineer. It was agreed that the Clerk should communicate with Dr. Mond on the subject of the suitability of the new Mond gas for street lighting, and write to the Board of Trade explaining the Council's position in regard to the Provisional Order, and asking an extension of time in order to carry it out.

The Board of Trade has granted a Provisional Order for the electric lighting of Whitley and Monkseaton. The area of supply is to comprise the whole of the urban district of Whitley and Monkseaton, but it is expressly provided that the powers granted by this Order shall not be exercised unless they are transferred to a limited company, approved by the Board of Trade for the purpose. Power is given to the Local Authority to purchase the undertaking after the expiration of a period of ten years "upon the terms of paying to the undertakers the fair market value of the undertaking as a going concern, that value to be determined in default of agreement by arbitration."

At last week's meeting of the City Council at Hereford it was reported that the electric lighting profit for the first year was sufficient not only to pay the interest, but also to almost discharge the first instalment of capital, £800. This was considered highly satisfactory, the amount to be borne by the rates being only £85. It was decided to increase the electrical engineer's salary to £200. The Gas Committee, in asking for £4000 more to install additional penny-in-the-slot meters, pointed out that there was not only a profit of £87 19s. 8d. on the 1174 slot meters already installed at a cost of £5442 12s. 8d., but it had saved the Committee raising the price to ordinary consumers, and when the loan on the gasworks was paid off next July they hoped to sell gas at 2s. 6d. per 1000 feet.

GENERAL.

The Local Government Board has sanctioned the borrowing by the Chorley Town Council of £7645 for a refuse destructor.

The Edmonton Urban District Council proposes spending £27,000 in erecting workmen's houses on the Brookfield Estate, Edmonton.

We understand that the City Councils of Sheffield and Edinburgh have both decided to do something to check the spread of consumption. The former intends to try and cure consumptive patients in the earlier stages of the disease, while the latter has decided to provide a retreat for hopeless cases.

At a recent meeting of the Northallerton Town Council, it was decided to obtain the sanction of the Local Government Board for a loan of £3000 for making new roads.

At last week's meeting of the Monmouth Town Council a letter was read from the Local Government Board, granting authority for a loan of £16,952 for public improvements.

The Rochdale Health Committee has resolved that 15,000 handbills be printed and distributed throughout the borough, stating the precautions to be taken against summer diarrhœa, scarlet fever, &c.

A Local Government Board inquiry was held last Friday at Ilford, by Col. Von Donop, R.E., into the application of the Urban District Council for sanction to borrow £106,737 for the construction of tramways and plant.

The Health Committee of the Darwen Town Council has decided to make an application to the Local Government Board to hold an inquiry into the epidemic of diphtheria which has been prevalent in the town for the last six months.

A Local Government Board inquiry has been held by Col. A. C. Smith, R.E., at Ryde, Isle of Wight, with reference to the application of the Town Council for sanction to borrow £600 for the purchase of horses, harness, and dust carts for scavenging purposes.

An inquiry has been held at Warrington by Mr. Manby, M.D., Local Government Board Inspector, into an application of the Corporation for sanction to borrow £9979 for the provision of a small-pox hospital at Great Sankey, and £8702 for the extension of the Borough Infectious Disease Hospital.

A Local Government Board inquiry was held last week at Broadstairs by Mr. H. H. Law, M.I.C.E., into the applications of the Broadstairs and St. Peter's Urban District Councils for sanction to borrow £4370 for works of sewerage, £1850 for purposes of street improvement, and £1710 for purposes of public walks and pleasure grounds.

At the monthly meeting of the Bromley and Beckenham Joint Hospital Board, it was decided to accept the tender of Messrs. William Smith and Son, of Croydon, amounting to £5998 10s., for the erection of new diphtheria wards at the Bromley Common Hospital, and to negotiate with the Public Works Loan Commissioners for the raising of the necessary loan.

At the last meeting of the Llangollen Urban Council, the Clerk read a letter from the Local Government Board stating that, in view of grave representations made to them by Mr. George Saint, a member of the Council, it must delay authorising the loan for improvements to the local Smithfield. The Board forwarded Mr. Saint's letter to the Council, and asked for an explanation as to its contents. The enclosure, which was read amid sensation and loud expressions of disapproval, asserts *inter alia* that the death-rate of the town—17·05 per thousand—shows the place to be in an unhealthy state, which Mr. Saint attributes to bad drainage. He considers the town, from its position, should be quite a sanatorium, and that the death-rate should not exceed 12 or 13 per thousand if the drainage were properly seen to by the Authorities. He suggested that the Local Government Board should send an Inspector down to make a house-to-house inspection of the district, and urges it not to sanction the raising of loans for purposes of market improvement, electric lighting, or to make the Town Hall secure until the drainage is set right. A heated discussion followed the reading of this letter. The Medical Officer said the charges made were groundless, and eventually it was agreed to send a letter to the Local Government Board to that effect.

Lord Lister will open the new operating theatres and children's ward at St. Thomas's Hospital on June 20th at four p.m. The theatres have been fitted with all the latest improvements for the carrying out of aseptic surgery, and the new block of buildings is provided with an artificial system of ventilation. The children's ward is elaborately decorated with pictorial representations of fairy tales and nursery rhymes in tiles, the cost being defrayed by one of the governors of the hospital.

With reference to some remarks reported to have been made by Councillor Bayley Marshall respecting the ownership of some alleged slum dwellings in Birmingham, the following letter has been received by Alderman Cook, in which it will be seen that Mr. Bayley Marshall expresses his regret that he spoke under a misapprehension of the circumstances:—"Richmond Hill, Birmingham, 31st May, 1901. Dear Alderman Cook,—I do not wonder that you should have felt aggrieved at the remarks made by me at the recent meeting of the Liberal Unionists in St. Bartholomew's Ward. I was certainly induced to believe (with many others) from statements which appeared in the *Gazette* newspaper, that you had an interest in slum property in Birmingham, and that the ownership of such property had induced you to abstain from the proper performance of your duties as chairman of the Health Committee. It would have been wiser on my part to have made inquiries from you before assuming the correctness of the insinuations made by the *Gazette*, and for this omission I tender you my hearty apology. I find on inquiry that you do not own and never have owned any slum property at all.—Yours faithfully, W. Bayley Marshall. P.S.—You are quite at liberty to publish this letter." In publishing Mr. Bayley Marshall's letter, the *Daily Gazette* emphatically denied that anything published in that journal justified any person in saying that it charged Mr. Cook with being an owner of slum property.

We extract the following from the *North British Daily Mail*:—"A special adjourned meeting of the Moffat Town Council was held on Tuesday evening—Provost Kennedy presiding—to consider the applications for the post of Sanitary Inspector and Burgh Surveyor, now vacant. There were over thirty applicants, including Bailie Easton, one of the magistrates of the burgh. Mr. Hamilton moved that Mr. John Fyfe, plumber, Paisley, be appointed. Mr. Johnstone seconded. Bailie Richardson nominated Mr. Easton, which was seconded by Mr. Steven. The applications and testimonials of the two candidates were asked to be read, and it was pointed out that Mr. Easton did not fulfil the requirements, inasmuch that he was not a plumber, and also that he had failed to produce three testimonials, as requested. Some vigorous discussion took place regarding the competency of appointing anyone not a plumber, in view of a former resolution of the Council, and on the legality of allowing Mr. Easton, if appointed, to pay the plumber work out of his pocket, as he proposed doing. The Chairman and Bailie Richardson advocated strongly the cause of their ex-colleague in the magistracy. On a division, Mr. Easton was elected by the casting vote of the Chairman, there being an equality of four votes, as in previous divisions. Mr. Johnstone, who characterised the finding of the meeting as 'a grave prostitution of the public interests,' formally entered his dissent, the other three members in the minority doing likewise. Mr. Easton is a clogmaker by trade." The action of the Council is one of the most discreditable performances we have yet recorded. The previous meeting was adjourned in order to let Mr. Easton retire from the Council. His application should never have been entertained, as he did not come up to the Council's own requirements. The whole thing is a job, and cannot be otherwise described.

The Health Committee of the Bradford Corporation has had under consideration a scheme for dealing with the Longlands insanitary area, concerning which it has been for some time pressed by the Local Government Board. The scheme is one drafted by the city architect, and will, if carried out, involve an expenditure of £60,000. The scheme provides for the housing of 840 people on the same spot, and the Committee adopted it after modifying it in some minor details. The Committee also decided to inspect certain land on the outskirts of the city with a view to accommodating some of the people away from the congested area.

Mr. W. O. E. Meade King, an Inspector of the Local Government Board, held an inquiry at Ripon on Thursday with respect to the application of the City Council for leave to borrow £5000 for works of sewerage and sewage disposal, and £3000 for purposes of street improvement. The City Surveyor (Mr. W. Edson) stated that the Corporation had 13 acres of land laid out at present for sewage disposal purposes, and it was intended to lay out another area of eight acres. The street improvements contemplated mainly consisted in widening and rounding off corners. The total amount of land required was 5580 square yards, for which provisional agreements had been made. There was no opposition to the application.

The fifty-seventh annual report of the Metropolitan Association for Improving the Dwellings of the Industrious Classes shows an increase of £226 13s. 6d. in the receipts from the gross rents, the amount received being £25,953 7s. 3d. as compared with £25,726 13s. 9d. in the previous year. The sanitary improvement of Farringdon-road-buildings, the largest of the properties belonging to the association, has been commenced, it is stated, one out of the five blocks having been dealt with during the year. New sanitary appliances have been provided throughout, and certain windows have been enlarged, while new ones have been added to increase the amount of light and air. A portion of the cost—£520 2s.—has been charged to the capital account of the building, while the balance—£1,330 15s. 5d.—has been paid out of revenue. Improvements in other properties are also reported. Out of an available balance of £8805 5s. 1d. the directors propose to pay a dividend at the rate of 4½ per cent. per annum on the ordinary consolidated stock, leaving £156 5s. 1d. to be carried forward.

At the recent meeting of the Public Health Committee of Derry Corporation, Dr. Ferguson, Medical Superintendent Officer of Health, submitted some remarks upon the report of Dr. C. Bigger, the Local Government Board Inspector, regarding the unsanitary condition of the city. Dr. Ferguson suggested an inspection of individual unsanitary houses and the remedying of the defects, but preferably putting the provisions of the Housing of the Working Classes Act into force, where the whole unsanitary areas could be cleared and suitable breathing spaces provided in congested districts. He admitted the great expense of the latter plan, but believed it would eventually pay in cash and the improved health of the poor and rich alike, "as zymotic disease," says Dr. Ferguson, "is no respecter of full purses more than empty ones." He advocated the establishment of manure depôts, and suggested utilising the present disfiguring foreshore between the shipyard and the Narrows. He adds—"Piggeries are a great source of nuisance in the borough, and permission to keep pigs should be restricted." In regard to the water supply, he says the Corporation can give a constant supply, having storage capacity in the reservoirs. There must be waste somewhere, which requires immediate attention. In conclusion, he admits there is no system of filtration, but as an analysis of the water is fair, it is not necessary at present to go to the expense of making filter beds.

At a meeting of the Parliamentary Committee of the Leeds Corporation last week, a short discussion took place on a proposal which is before the public for constructing a line of light railway between Wakefield and Leeds. The line, if sanctioned by the Commissioners, would enter the Leeds city boundary for a few yards, and the Committee decided to advise the Council to oppose the project.

On Monday night there was a unique conversazione at the Guildhall, when the Corporation of London welcomed a section of the Mayors and members of the metropolitan Borough Councils. The capacity of the Guildhall will only accommodate some 2000 guests with comfort, hence the necessity for determining previously by ballot those municipalities who should be entertained first. They prove to be the City of Westminster, Battersea, Chelsea, Deptford, Finsbury, Greenwich, Hackney, Hammersmith, Holborn, Islington, Lewisham, St. Pancras, Shoreditch, Southwark, and Stepney. The remaining thirteen Borough Councils were received on Tuesday night, when precisely the same programme was gone through. In addition to the officers of the several metropoliton boroughs, invitations were issued to the members of the present and late Cabinet, the Lord Chief Justice (who was present), the metropolitan M.P.'s, the Livery Companies, the chairman and deputy-chairman of the London County Council, &c. The guests were received by the Lord Mayor and Lady Mayoress. The band of H.M. Grenadier Guards performed a programme of music, in the Council Chamber there was vocal and instrumental music, an entertainment was given by the Lawler Quintette, and dancing took place in the library. On each evening the Lord Mayor, Alderman Frank Green, spoke from the rostrum, welcoming most cordially the representatives of the new metropolitan boroughs.

PERSONAL.

Mr. Arthur Kent, of Hanley, has been appointed Sanitary Inspector for Stourbridge.

Mr. John Yorke has been appointed Inspector of Nuisances for Brierley Hill, at a salary of £80 per annum.

Mr. W. J. Bevan, of Longton, has been appointed manager of the Coventry Sewage Farm, at a salary of £250 per annum.

The Local Government Board has sanctioned the application of Dr. Swenden as Medical Officer for the rural district of Croft.

Mr. L. Rawlinson, deputy town clerk of St. Helens, has been chosen as town clerk for Leamington, at a salary of £400 per annum.

Miss Bentham, of Spennymoor, has been appointed Sanitary Inspector for Middlesbrough, at a salary of £78 per annum and uniform.

Mr. J. Franklin, of Stockport, has been appointed Inspector of Nuisances for the east district of Stockton rural district, at a gross salary of £130 per annum.

The Local Government Board has approved the appointment of Mr. Mills as Sanitary Inspector, and Dr. W. M. Clendennin as Medical Officer for Coseley.

Mr. J. H. Cawthra, the borough electrical engineer at Swansea, has been selected one of three candidates for the post of electrical engineer at the municipal station at South Shields.

Mr. Ernest H. L. Dickson, who for the past five and a-half years has occupied a position as assistant engineer at the Cheltenham Corporation Electricity Works, has just ceased that connection on his appointment to a more lucrative post at Salford.

Mr. B. W. Baillie has been re-appointed Sanitary Inspector for Northfleet.

Dr. P. R. Lewis has been appointed Medical Officer at the Bromyard Workhouse.

Dr. Groves has been re-appointed Medical Officer of Health for Woodford urban district for three years.

The Local Government Board has sanctioned the re-appointment of Mr. Alfred Flint as Inspector of Nuisances for the urban district of Bexhill at a salary of £140 per annum.

Mr. J. P. Evans, Beeston, Nottingham, has been appointed surveyor to the Kiveton Park Rural District Council. The appointment is worth £200 a year, with house, coals, and gas.

On Monday last the Leamington Town Council appointed as Town Clerk of the borough Mr. Leonard Rawlinson, Deputy Town Clerk of the county borough of St. Helens. The salary is £400 per annum with the services of a paid assistant.

Dr. Logan Taylor, eldest son of Dr. M. H. Taylor, has been appointed assistant to Surgeon-Major Ross, who is well known by his writings on malarial fevers conveyed by mosquitoes. The expedition is to follow up Major Ross' discoveries, and try, by destroying on a large scale the breeding places of that particular mosquito, to improve the health of the West African Coast. The experiments are to be conducted first at Freetown, Sierra Leone. The expedition is being supplied by Glasgow and Liverpool merchants.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2231.—Sanitary Building Construction: Examinations by Various Bodies.—"A. M." writes:—"Can you give me any information as to examinations for gold medal for sanitary building construction, where and when held, fees, &c?"

Answer.—Examinations in building construction are conducted by the Science and Art Department in the month of May in various towns in the kingdom. Information on the subject may be obtained on application to the Secretary, Science and Art Department, South Kensington. A bronze medal (not gold) is awarded for a first-class pass in the honours stage. Examinations are also held in the same subject by the City and Guilds of London Institute, particulars of which will be found in the "Programme of Technological Examinations of the City and Guilds of London Institute for the Session 1900-1," price 1s. 2d. post free, obtainable from the office of this journal; and by the Worshipful Company of Carpenters, Carpenters' Hall, London Wall, London, for particulars of which the querist should write the Secretary.

2232.—Plans for New Dwellings: Erecting Houses After Disapproval of Plans.—"J. K. L." writes:—"Plans for four houses were submitted to this Council which were disapproved on the ground that the method of drainage was unsatisfactory, the drains being shown to discharge into a combined cesspool with no overflow on to land, and without land to dispose of contents. The cesspool, being close to a highway, is likely to become a nuisance. The Council required one cesspool for each house, as the responsibility of emptying rests with the occupiers. Since the plans were disapproved the building has been commenced, and the work has considerably advanced, although he has received notice to discontinue. I am informed that all my Council can do in the matter is to direct how the drainage shall be done. This is practically impossible, as the ground is insufficient and unsuitable for building purposes, as it rises about 20ft. at the point near the cesspool. I enclose copy of building bye-laws. Will you kindly advise what course can be taken in this case? Has the Council no case against a person proceeding to build before plans are approved?"

Answer.—If the plans were in conformity with the building bye-laws, and the disapproval was made solely on the grounds stated by the querist, the Local Authority will be unable to succeed in proceedings against the owner for a breach of the bye-laws. Sec. 158 of the Act of 1875 applies to the case wherein is enacted that "where work is commenced after notice of disapproval of plans, *and is not in conformity with any bye-law*, the

"In future the two great illuminators will be called—one the 'Sun,' and the other, to ear-mark it from its competitor, the 'Kitson.'"—***From "Punch," May 27th, 1901.***

A REVOLUTION IN STREET LIGHTING.

THE KITSON

Incandescent Petroleum Light

IS THE

CHEAPEST & MOST BRILLIANT SYSTEM OF STREET LIGHTING

THAT HAS YET BEEN PRODUCED.

It can be seen on Portland Place, lighting the street from the Langham Hotel to Park Crescent.

It AVOIDS the NUISANCE OF TEARING UP THE STREETS.

A Committee of the Aberdeen Town Council, in a recent report, made the following statement:—

"We may at once say that no comparison can be made between the Kitson Light and ordinary, or Incandescent, Gas Lighting, as these are completely put into the shade by the Petroleum Light, and, comparing it with Electric Lighting, it is very much superior both as to brilliancy and cost."

Before expending enormous sums in Electric Lighting, it would be worth while to investigate this System.

Council may pull it down." But in this case it does not appear that the work is in contravention of the bye-laws, and the owner may proceed with the erection of the building so long as he does not contravene any bye-law. The Local Authority should ensure that all the provisions of the bye-laws are being carried out, and if the notices required by Clause 102 of the bye-laws relating to notices have not been observed proceedings may be taken against him. They may also strictly enforce the requirements of Clauses 67 to 74 of the bye-laws relating to drainage.

2233.—New Buildings; Open Space at Rear.—"Building" writes:—My Council have the Model Bye-laws of the Local Government Board in force with regard to the question of an open space at rear. A difference of opinion has arisen. The clause reads, "Every person who shall erect a new domestic building shall provide in the rear of such building an open space exclusively belonging to such building,' &c. The clause further states, 'If the height of such building be 15ft., he shall cause such distance to be 15ft. at the least. If the height of such building be 25ft. he shall cause such distance to be 20ft. at the least.' Does this in your opinion mean that if the height of a building be, say, 20ft., the air space shall be 15ft. or 20ft?"

Answer.—The proper interpretation to be placed upon the clause is that where the height of a building is over 15ft. and under 25ft. the distance across the open space (from the rearmost wall of any part of the building excepting a water-closet) must be 15ft.

2234.—Duties of Inspector of Nuisances.—"Inspector" writes:—"Will you kindly advise whether it is the duty of an Inspector of Nuisances to carry out the duties as in 1, 2, and 3, unless specially appointed to do so, viz.:—(1) Inspector of Factories and Workshops; (2) Inspector of Common Lodging-houses; (3) Inspector under the Dairies, Cowsheds, and Milk-shops Order. Further (4) Do the duties as above come within the Order of the Local Government Board of the 23rd March, 1891? (5) Can an Inspector of Nuisances be dismissed at the pleasure of the Council at the end of any year, when his appointment is an annual one, and subject to the approval of the Local Government Board? (6) What power have the Local Government Board over a Local Authority with regard to an Inspector of Nuisances? (7) Have the Local Government Board any control in respect to the amount of salary an Inspector of Nuisances shall be paid? (8) Where a Local Authority has divided the office of Surveyor and Inspector of Nuisances with the approval of the Local Government Board, would the Local Government Board allow the Local Authority to again combine the offices?"

Answer.—(1) Except in large populous boroughs where a separate Inspector may be appointed as Inspector of Workshops, an Inspector of Nuisances may, in our opinion, be required to perform the duties without being specially appointed to do so. (2) No special appointment is necessary; the Inspector of Nuisances is bound to perform the duties. (3) Such duties are prescribed within the terms of the General Order of the Local Government Board. (4) Yes. (5) Yes. (6) and (7) When a portion of the Inspector's salary is paid by the County Council the Local Government Board have power to veto any appointment of, and prescribe the salary which should be paid to, an Inspector of Nuisances. (8) If the offices of Surveyor and Inspector have been divided at the request of the Local Government Board, they would not, in our opinion, assent to the re-union of the said offices. The querist should refer to the General Order of the Local Government Board, which will be found in Himes' excellent "Practical Guide to the Public Health Acts," price 15s. net.

2235.—Sanitary Engineers' Examination: Books to Study.—"Constant Reader" writes:—"Please advise what books should be studied for the examination for Sanitary Engineers?"

Answer.—Reid's "Practical Sanitation," price 6s.; Jensen's "House Drainage and Sanitary Fitments," price 5s.; Jensen's "Modern Drainage Inspection and Sanitary Surveys," price 2s. 6d. are recommended.

2236. — Emptying Sewage into a Highway Drain.—"J. C. P." writes:—"The houses in my district are at present drained into cesspools, but in one part of the district two houses have their drains separately connected to a surface water drain, which is only intended for road drainage. A nuisance is caused by the accumulation of sewage in the ditch into which the drain discharges. In addition to the above there is also an overflow from a cesspool connected to the surface-water drain. There are two owners for the three houses, and they refuse to disconnect from the surface-water drain, contending that the surface-water drain receiving the drainage of more than one house is a sewer. Can the Local Authority compel the owner to disconnect the cesspool overflow from the surface-water drain, and also the other owner to disconnect his drains from the surface-water drain and from all cesspools?"

Answer.—We are of opinion that the Local Authority would not succeed in proceedings to require the disconnection of the drains from the pipe in question. It is the duty of the Authority to provide a sewerage system, and it would appear that they are endeavouring to shirk this obligation, and transfer it to individual owners. In Fordom *v.* Parsons (1894), 2 Q.B. 780; 58 J.P. 765, where the facts were similar to those mentioned by the querist, the Local Authority having instituted proceedings against the respondent for the abatement of a nuisance caused by a drain emptying into a ditch, the justices dismissed the complaint, and on appeal by the Local Authority judgment was given for the respondent.

THE CONSTRUCTION OF ROADS, PATHS, AND SEA DEFENCES.

By Frank Latham, C.E.

(Borough Engineer and Surveyor, Penzance. Author of "The Sanitation of Domestic Buildings," &c.)

(Continued from page 513.)

CHAPTER III.—LINE OF ROAD.

Bearing the question of gradients in mind, the next matter for consideration is the location of a road which would provide the shortest route for the main portion of the traffic.

In planning new roads it is often found necessary to deviate from a direct line, in order to meet certain existing roads or to provide for the traffic to some village, or owing to the desirability of taking a pleasanter route. So that it is seldom that a road can be laid out in such a direct line as could be desired, from an economic point of view.

Apart from these, there are other influences which are too often allowed to affect the line of a road, and these require a larger amount of serious attention than is generally given to them. These causes consist generally in the expense of constructing bridges over rivers, or of raising a road by means of embankments above low and flat lands subject to inundation during high floods.

Sir Henry Parnell remarks on this point, "The peculiar circumstances of a river may render it necessary to deviate from a direct line in laying out a road. A difficulty may arise from the breadth of the river requiring a bridge of extraordinary dimensions, or from the land for a considerable distance on the side of the river being subject to be covered with water to the depth of several feet in floods. In these cases it may appear, upon accurately calculating and balancing the relative inconvenience and expense of endeavouring to keep a straight line and of taking a circuitous route, that upon principles of security, convenience, and expense, the circuitous course will be the best.

"In general, rivers have been allowed to divert the direct line of a road too readily. There has been too much timidity about incurring the expense of new bridges, and about making embankments over flat land to raise the roads above the level of high floods.

"These apprehensions would frequently be laid aside if proper opinions were formed of the advantages that arise from making roads, in the first instance, in the shortest directions and in the most perfect manner. If a mile, half a mile, or even a quarter of a mile of road be saved by expending even several thousand pounds, the good done extends to posterity, and the saving in annual repairs and horse labour that will be the result will before long pay off the original cost of the improvement."

But little consideration should be required, to convince all concerned, that where practicable the route selected for a road should be the one with the least hills and gradients along its course, provided that the length of such road would not be unduly increased in so doing.

The importance attached to this matter, is being felt more and more as the modern methods of locomotion come into use.

A steep gradient to ascend on an outward journey means one to descend on the return. The risks incurred in descending steep hills are sometimes considerable, resulting at times in serious accidents, and the additional energy required in ascending similar inclines often necessitates the employment of extra horse labour; at the best of times they are fatiguing and entail much loss of time.

A further important consideration is, that the amount of repair and attention that steep gradients require are much above that of level roads, chiefly due to the use of skids on the wheels of vehicles, and to erosion of the metal caused by water scour on the surface.

With modern roads, with their smooth surface, there is frequently a danger of a horse slipping and falling down in descending steep inclines, and there is also the difficulty for a horse to gain the desired foothold to enable it to draw a weight up such gradients.

The steepest gradient that should prevail in the line of a new road—excepting where, owing to circumstances, it is necessary to depart from the rule—is that known as the "ruling gradient."

This "ruling gradient" is that inclination to be determined that will require but a moderate additional force in ascending, and no difficulty or danger in descending, and will present no practical impediment to any ordinary traffic.

Mr. Thomas Codrington considers that the ruling gradient on a macadamised road should be 1 in 30. He says: "On a level macadamised road in ordinary repair the force which the horse has to put forth to draw a load may be taken as $\frac{1}{30}$th of the load. But in going uphill the horse has also to lift the load, and the additional force to be exerted on this account is very nearly equal to the load drawn divided by the rate of gradient. Thus, on a gradient of 1 in 30 the force spent in lifting is $\frac{1}{30}$th of the load, and in ascending a horse has to exert twice the force required to draw the load on a level. In descending, on the other hand, on such a gradient, the vehicle, when once started, would just move of itself without pressing on the horse. A horse can, without difficulty, exert twice his usual force for a time, and can therefore ascend gradients of 1 in 30 on a macadamised surface without sensible diminution of speed, and can trot freely down them."

Messrs. Law and Clark say: "Sir John Macneil, in 1836, maintained that no road was perfect unless its gradients were equal to or less than 1 in 40. In thus limiting the ruling gradient to 1 in 40, he justifies the assertion by the much greater outlay for repairs on roads of steeper gradients. For instance, he adduces as a fact not generally known, that if a road has no greater inclinations than 1 in 40, there is 20 per cent. less cost for maintenance than for a road having an inclination of 1 in 20. The additional cost is due not only to the injury by the action of the horses' feet on the steeper incline, but also to the greater wear of the road by the more frequent necessity for sledging or braking the wheels of vehicles in descending the steeper portions."

Sir Henry Parnell considers 1 in 35 to be the ruling gradient, and remarks as follows:—"An inclination of 1 in 35 is found by experience to be just such an inclination as admits of horses being driven in a stage coach with perfect safety when descending in as fast a trot as they can go; because, in such a case, the coachman can preserve his command over them, and guide and stop them as he pleases. A practical illustration that this rate of inclination is not too great may be seen on a part of the Holyhead Road, lately made by the Parliamentary Commissioners on the north of the city of Coventry, where the inclinations are at this rate, and are found to present no difficulty to fast driving, either in ascending or descending. For this reason it may be taken as a general rule, in laying out a line of new road, never, if possible, to have a greater inclination than that of 1 in 35. Particular circumstances may, no doubt, occur to require a deviation from this rule; but nothing except a clear case that the circuit to be made to gain the prescribed rate would be so great as to require more horse labour in drawing over it than in ascending a greater inclination, should be allowed to have any weight in favour of departing from this general rule. On any rate of inclination greater than 1 in 35 the labour of horses in ascending hills is very much increased. The experiments detailed in the Seventh Report of the Parliamentary Commissioners of the Holyhead Road, made

by a newly-invented machine for measuring the force of traction or power required to draw carriages over different roads, fully establishes this fact."

The following is a table contained in the appendix of Sir Henry Parnell's work of the general results of experiments made with a stage coach on the same description of road; but on different rates of inclination, and with different rates of velocity, on the Holyhead Road:—

Rates of inclination.	Rates of travelling.	Force required.
1 in 20	6 miles per hour	268 lb.
1 in 26	6 ,, ,, ...	213 lb.
1 in 30	6 ,, ,, ...	165 lb.
1 in 40	6 ,, ,, ...	160 lb.
1 in 600	6 ,, ,, ...	111 lb.
1 in 20	8 ,, ,, ...	296 lb.
1 in 26	8 ,, ,, ...	219 lb.
1 in 30	8 ,, ,, ...	196 lb.
1 in 40	8 ,, ,, ...	166 lb.
1 in 600	8 ,, ,, ...	120 lb.
1 in 20	10 ,, ,, ...	318 lb.
1 in 26	10 ,, ,, ...	225 lb.
1 in 30	10 ,, ,, ...	200 lb
1 in 40	10 ,, ,, ...	172 lb.
1 in 600	10 ,, ,, ...	128 lb.

Where long steep inclines cannot be avoided, it is desirable to divide them up into lengths, by introducing at intervals short lengths of road of less gradient, which would serve to relieve the heavy strain from horses when drawing loads up the hill.

In some instances where new roads are necessary, but owing to the elevated contour of the land, and circumstances surrounding the question, a steep incline cannot be avoided, then in such cases it is sometimes advisable to lessen the incline by cutting through the summit.

The incline of a hill may in some instances be lessened by making up the road at the foot with either the material removed from the summit, or by means of other suitable substance. This road should be banked up, with slopes on each side, which, if necessary, may be further supported by retaining walls.

This procedure can often be adopted with considerable advantage in overcoming deep valleys. It is far from an uncommon occurrence to meet with a steep descent to be almost immediately followed by an ascent; in such cases it would be an improvement if the valleys between were more or less filled up. This operation not only saves a lot of tedious up and downhill work, but also shortens the distance.

In locating a line for a new road, a preliminary reconnaissance should be made. It is necessary, in so doing, that the principal characteristics of the country through which a new road is to be carried should be carefully noted.

This work is much simplified if a reliable map of the district is obtained, but should such maps not be procurable, then the work of reconnoitering will be considerably increased.

Upon the map—which should accompany the engineer when making his examination of the country—the points which appear to afford the most suitable lines can be noted, and fixed with sufficient accuracy to enable sketches to be made previously to a full survey with levels; after which the route can be finally laid out.

Contour maps, showing the principal elevations of the country, are sometimes available, and in such cases the work to be done is much facilitated, as the greater portion of the planning, after the preliminary examination, can be done on the map.

In considering the lines selected, note should be made as to the available material for embankments, where they appear to be necessary; the nature of the material to be excavated where such work is required, in which case the particular geological formations, over which it is proposed that the lines should pass, should be ascertained. The position of quarries from which stone and gravel could be obtained should be noted, together with any general circumstances and conditions that must be in favour of or against any particular line that might be selected.

It is desirable, that in cases where a turning or curve takes place on an incline, that for the safety and convenience of traffic, this deviation from the direct line should be of as large a radius as possible, and the incline at such points should be reduced.

It is sometimes found desirable to alter the line of an existing road for the purpose of reduction of distance, or improvement in gradients. This question, whatever advantages may be derived from the diversion, is one of much importance; not only the convenience of those who use the road should be considered, but the possible injury to property by the alteration must be borne in mind, or otherwise cases of compensation may arise. The advantage of such diversions to the public generally, should carry much weight, but care should be taken that as little injury as possible should be caused to neighbouring property.

Upon the line of a road being finally determined, the next business is to stake out the route. This is generally done by driving a line of wooden stakes into the ground all along the course of the proposed road. These stakes are placed at about 100ft. apart for straight roads and closer together at curves, and are so placed as to define the centre line of the work; levels are then taken along the line at each stake, from which a longitudinal section is drawn. Cross levels are also taken at intervals where considered necessary. Upon these longitudinal and cross sections the finished levels are indicated.

Width of road.—The width of the roadways of towns up to recent years has been too often insufficient for the conduct of the traffic, and in many cases considerable outlay has been necessary to remedy these congested conditions, in purchasing and removing property for street-widening purposes. This is an experience that nearly every town has had at one time or another. In country roads situate between towns of importance, and thereby subjected to much traffic, the width of such roads should not be less than 36ft., and should include a 6ft. path on one side, but in ordinary country roads not so situate the width is not of so much importance, as it is seldom that more than two vehicles are required to pass one another at a time. A width sufficient to meet the requirements of the traffic in each direction is all that is needed, and the cost of an unnecessary width of roadway to construct and maintain is avoided. Such roadways therefore require to be only about 18ft. in width. Although the roadway need not be of greater width, yet it is most desirable that the distance between hedge and hedge should be of the full width of 30ft. to 36ft. This may be accomplished by leaving a strip of grass land at each side through which footpaths could be made and sub-drains carried. By so arranging the width, the road is exposed to the full benefit of the sun and wind, which is essential to obtaining a dry and good wearing surface.

On this subject Mr. Macadam, in answer to the question, "What width would you in general recommend for laying out a turnpike-road?" remarks:—"That must depend upon the situation. Near great towns roads, of course, ought to be wider than further in the country. Roads near great towns ought not to be less than 30ft. or 40ft. wide; but at a distance from great towns it would be a waste of land to make them so wide." (Evidence before a Committee of the House of Commons, 1819.)

Road boundary walls, &c.—Hedges and close-boarded fences should not be placed at the sides of country roads unless they are kept low enough or at sufficient distance away, so as not to obstruct the action of the wind and sun. The free exposure of country roads to

both the drying effects of the wind and sun are most essential, in order to maintain the surface in good condition for any length of time. Attention to this is important, not so much from the fact of the convenience and comfort afforded by a dry road, but that the effect of wet has a great tendency to weaken and cause the road to wear more quickly and cut under the weight of the traffic.

Trees in streets also have an injurious effect on roads, and sometimes are the cause of a road being kept wet for a considerable time by the dripping of water from their leaves

From another point of view, however, it is desirable to have trees in roads, as they afford shade from the blaze of the sun, which in some streets in summer time is almost unbearable to horses as well as to pedestrians. Trees are further a great attraction, and beautify the perspective of thoroughfares. In the country where trees are planted on each side of the road special attention should be given to see that no hedges or walls are allowed to exist along the line to obstruct the free action of the wind under the trees.

In selecting trees for street planting the description of tree must be considered in conjunction with the

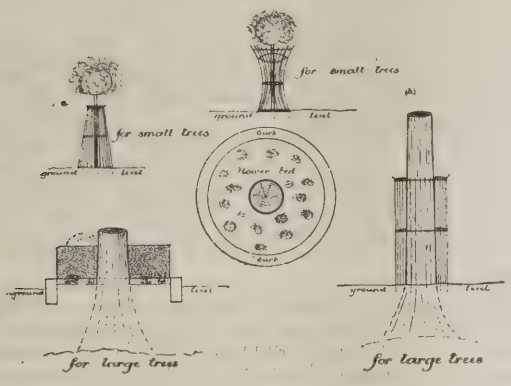

Fig. 2.

locality and conditions to which they will be subjected. Trees of light foliage and small growth are more suited for this purpose than the more dense and larger variety. Where planted in pavements it is advisable to place an iron grating over a portion of the earth surrounding the tree so as to admit air and a small quantity of water to the roots; the earth over the roots is in some towns allowed to remain exposed and frequently used as a flower bed. It is further advisable that all young trees growing in streets should be protected by a tree guard, as illustrated—Fig. 2—to prevent the trunk from being injured by horses or mischievous persons.

National Health Society.

OFFICIAL TRANSACTIONS.

Special Training Lectures.—The next course of training lectures for the Certificate of the Sanitary Inspectors' Examination Board, and for the Diploma of the National Health Society, will be commenced on Monday, September 16th. Full particulars and prospectus can be obtained from the Secretary, 53, Berners-street, W.

A Local Government Board inquiry was held at Egremont, before Mr. E. Petronell Manby, M.D., last week, with reference to an application by the District Council for sanction to borrow £15,500 for hospital extensions.

SANITARY LAW (A).*

By Trevor Edwards, Esq., West Riding Solicitor.

THE PUBLIC HEALTH ACT, 1875, AND THE MODEL BYE-LAWS THEREUNDER.

(*Continued from page* 515.)

I have taken up more of your time than I intended in considering what I may call the approach to the Public Health Act, 1875. I will now briefly sketch the procedure in connection with, say, three subjects:—First, the course to be taken by an Inspector of Nuisances in relation to unsound meat; secondly, the course to be taken in relation to a common nuisance; and, thirdly, I will refer to the sections of the Act which confer the power of entry upon private premises.

First, as to unsound meat:—There are few duties that ought to weigh so heavily upon Inspectors as those in relation to unsound meat, and because these duties are so important and urgent, the powers conferred upon them are correspondingly large. Whenever you find the Public Health Act conferring drastic powers, you may at once assume that the Legislature has attached very great importance to the underlying subject. The greater the effect of an act upon life or health, the greater the power of protection or prevention. The code dealing with unsound meat is all contained in four sections, 116 to 119. Section 116 gives the Inspector of Nuisances every reasonable power to go wherever he likes in his district to inspect meat, food, fish, fruit, milk, &c., exposed for sale or deposited in any place for the purpose of sale, or of preparation for sale and intended for the food of man. If medical men could only give us statistics of illness and deaths from the consumption of unsound food, especially meat, we should all be horrified. The framers of these sections were not without much knowledge on that point, hence the large and arbitrary powers. The possession of these powers confers a grave responsibility. I sometimes think that the powers are not sufficiently and systematically exercised, especially with respect to compounded foods, such as sausages and the like. Far be it from me to detract from the general honesty of those who provide our food supplies, but in every community there are some who, by hook or by crook, will endeavour to enrich themselves even at the cost of the sufferings of others. It is against such people that Inspectors of Nuisances may very properly and rigorously exercise their great and responsible duty.

When an Inspector in performing his duty under this part of the Act comes to deal with any article of food he may be in doubt whether the food falls within the statute or not, although he may be convinced that it is most suspicious. Such a situation at once points to the necessity of the Inspector possessing knowledge of an expert nature; and this remark applies to all other duties under the Act involving executive authority. The responsibility, therefore, of deciding whether to seize or not calls for qualities in him other than those we are considering this afternoon, namely, a mere knowledge of the Public Health Acts.

The question which he has to decide is whether the food is sound or unsound within the meaning of the Act of Parliament, this is (as in most things) a question of degree. If it is not unsound and he proceeds with the case he may be the means of involving his Authority in considerable expense, and thereby lessen his own reputation. If, on the other hand, he gives the owner the benefit of *his* doubt he may let loose upon those

* Third Lecture delivered to the Health Officers of the West Riding of Yorkshire April 27th, 1901, at the Philosophical Hall, Leeds.

who buy the "doubtful" food the cause of much discomfort or illness, or even death. The circumstances may be such that time will not allow the Inspector to consult the Medical Officer of Health. It is therefore imperative that the Inspector should be so well versed in all conditions of unsound foods, and also the appearances, smell, &c., attending on decomposition and degeneration as to enable him to discharge his task without anxiety.

If he exercises his executive authority and seizes the article he must take it before a Justice who, in case he condemns it, corroborates and supports the action of the Inspector, and thus divides the responsibility. The Justice has thus an equal responsibility cast upon him. Although a different opinion has been expressed, in my judgment the Justice must examine the article himself before making an order. If he does make an order then it will be the duty of the Inspector to destroy the food or otherwise dispose of it so as to prevent it from becoming the food of man.

Secondly, I turn to a section known to every one of you. I refer to Section 91. This is the section that deals with general nuisances. The first of the nuisances enumerated in the section is described thus:—

"Any premises in such a state as to be a *nuisance or injurious* to health." You will notice the section says nuisance *or* injurious to health, not nuisance *and* injurious to health. There may be a nuisance which, although not injurious to health, may so incommode or inconvenience persons as to diminish their comfort of life.

If you have any difficulty in judging for yourself whether any condition of things that you may meet with in your district is a nuisance within Section 91 of the Act, you will invariably have time to confer with the law officers of your Authority, though if you have carefully read the section you will probably not have many instances where you need take that course.

Lack of time compels me to pass unnoticed the other classes of nuisance specified in this section. Having satisfied yourself that a nuisance exists, it is then your duty to report it in the proper phraseology of the Act to the Sanitary Authority, who will inquire into it upon your report, and if they confirm your opinion will order a notice to be served upon the owner or the occupier, as the case may require, to abate it. The further procedure in the event of default is prescribed in great detail.

Before touching on my third point I would especially ask you to note Section 92, which declares that:—"It *shall be the duty* of every Local Authority *to cause to be made* from time to time *inspection* of their district, with a view to *ascertain* what nuisances exist calling for abatement under the powers of this Act, and to enforce the provisions of this Act in order to abate the same; also to enforce the provisions of any Act in force within their district requiring fireplaces and furnaces to consume their own smoke."

The Act of Parliament thus expressly lays upon Sanitary Authorities the duty of having periodical inspections made of their district, and Inspectors are the Authority on the spot. If ever you have any doubt as to the limit of your duty under the Act I would advise you to read Section 92—you cannot want a wider charge than is given there. It is wholly wrong, as some think, that a Sanitary Authority or its officer must be put in motion—the above section makes it clear above all doubt that the primary principle of the Sanitary Code is to *prevent* harm and not merely to remedy it. I have been told by chief constables that they reckon their most capable officers to be those who keep their beats *free from crime* and offences, and not necessarily those who have the largest number of prosecutions. Let the same apply to Inspectors of Nuisances with even greater force, and see to it that by vigilance and foresight your district is *kept free from nuisances*. It will show that you have brought to bear upon the people of your district, not the powers of the law, but your moral force, which is far more effective. You will find—and find increasingly—that if you point out a sanitary defect or what will culminate in defect to owner or occupier in a proper manner and indicate how it can be avoided or remedied, you will, in the generality of cases, find that they will do what is right and also award you their thanks in mind if not in words. At times, of course, it may be necessary to remind them that you have the law to fall back upon. If, however, you commence at the outset to terrorise people with law they will fight you, and if you flaunt the Public Health Act too much in their faces it will only have the effect of creating prejudice against you.

(*To be continued.*)

SHOULD SANITARY INSPECTORS WEAR UNIFORMS?

An objection on the part of a Sanitary Inspector to wear a uniform led to a lively half-hour at a recent meeting of the Lambeth District Council.

The Public Health and Sanitary Committee reported that Mr. Ernest Howes, Sanitary Inspector for Trinity Ward, had refused to be measured for and to wear the uniform prescribed by the Council. The Committee had interviewed the Inspector, who adhered to his refusal, and declined to resign his appointment when called upon to do so. The Committee therefore recommended that the Inspector be dismissed from the service of the Council for insubordination and disobedience to orders, and that the Local Government Board be informed accordingly.

The Mayor read a letter from the Inspector, in which he stated that he did not absolutely refuse to wear the uniform, but informed the Committee that he would appeal to the Local Government Board on the point. He had now appealed to that body, and as a result withdrew his objection. In these circumstances he hoped the Council would remove his suspension, and allow him to resume his duties.

Councillor Barnard moved that the apology be accepted.

The Mayor did not think this was an adequate apology. Mr. Howes was extremely rude to the Committee, and the matter should be referred back in order that he should offer a proper apology.

Councillor Sharp rose to speak.

The Mayor, whose eye was not caught by Councillor Sharp, put the motion to refer the matter to Committee, while the Councillor was on his feet, and declared it carried.

Councillor Sharp: It was my intention, Mr. Mayor, to oppose the matter going back.

The Mayor: Next business.

Councillor Sharp protested against being "snuffed out" in this way.

The Mayor: Order, order.

Councillor Sharp: I protest against your conduct in refusing to allow me to speak.

The Mayor: You will have a chance of speaking when the matter comes up again.

Councillor Devereux joined in the protest, and said it was also his intention to speak had not the Mayor rushed the voting.

The Mayor: Order, order. Next business.

Councillor Devereux moved the adjournment of the Council as a protest against the action of the Mayor, but the motion was negatived.

SOCIETY OF ENGINEERS.

A VERY interesting visit was made by the members and associates of the Society of Engineers on Wednesday, June 12th, 1901, to the air-compressing station for the Shone system of sewage ejection at the sewage disposal works, Erith, Kent, and the engineering works of Messrs. Fraser and Chalmers, which are also situate at Erith.

Amongst those present were Mr. Charles Mason, president; Messrs. Percy Griffith and D. B. Butler, vice-presidents; Messrs. J. Bernays and W. G. Peirce, past-presidents; Mr. Maurice Wilson, member of Council; and Mr. Perry F. Nursey, secretary.

THE AIR-COMPRESSING STATION.

The Erith sewage disposal works, in which the air-compressor plant is working, are situate in the Manor-road, Erith, at the east boundry of the district on the banks of the river Thames, and occupy about two acres of land. The gas engine air compressors are four in number, being two sets in duplicate. The first pair produce the compressed air for working the Shone ejectors for pumping the low-level sewage. These engines were made by Messrs. Crossley Brothers, and comprise two Otto gas engines and air cylinders, each to compress 158 cubic feet of free air per minute to 11 lb. per square inch. The second pair produce the compressed air for the sludge pressing and for driving the mixing machinery. The gas cylinders indicate 25 horse-power each engine, and the air cylinders are capable of delivering 250 cubic feet of 100 lb. per square inch of air per hour. All four engines have automatic arrangements for throwing the air cylinders out of work when the working pressure in the receiver is reached. The second pair have this apparatus so arranged that the air cylinders can be entirely thrown out of work for any desired period. In addition to the foregoing, small air pumps are fixed in each ejector chamber in order to pump out the condense water from time to time as it accumulates in the chambers. Dowson gas is used for the gas engines, and is produced by the plant erected at the works by Messrs. Paisley, Welsh, and Co.

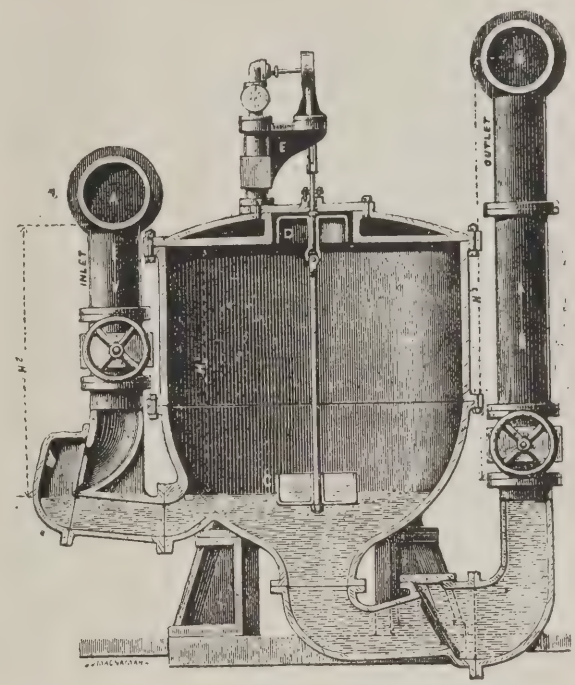
The air main is laid at a depth of about 4ft. along the Manor-road, High-street, West-street, Lower-road, and Lower Abbey-road, to the several automatic ejectors situate in those roads, the last station being about three miles from the works. Following are particulars of station plant:—

Station No.	Name of station.	No. of ejectors.	Discharging capacity of each ejector in gallons per minute.	Size of air supply, inches.	Size of air exhaust pipe. inches.
1	Appold-street	2	300	2½	2½
2	High-street	2	200	2	2
3	Lower-road	2	150	2	2
4	Station-road, Belvedere	2	150	2	2
5	Lower Abbey-road	2	50	2	2

The compressed air is delivered to the ejector stations through 4600ft. run of 4in. cast iron socket pipe, jointed with yarn and lead, and 10,900ft. run of 3in. similar pipe. All the pipes were tested to a pressure of 40 lb. per square inch. The fall in pressure in one hour does not exceed 5 lb. The compressed-air pipe is provided with stop valves close to each of the automatic valves, so that each of the ejectors can be repaired independently of the working of the others. Syphons for drawing off water are constructed at several points in the air main.

THE SHONE EJECTOR SYSTEM.

The Shone system of sewerage may be briefly described as a system of distributed stations for the lifting of sewage, worked from one central station by means of compressed air, whereby the whole drainage area is divided into a number of compact districts, each with its separate outfall and discharging station, the discharge from all the stations converging into one common main leading to the ultimate common outfall. The system is applicable wherever the sewage of a town or district requires to be lifted. Annexed is a sectional view of Shone's pneumatic ejector.



The motive power employed is compressed air, and the action of the apparatus is as follows:—The sewage gravitates from the sewers through the inlet pipe A into the ejector, and gradually rises therein until it reaches the underside of the bell D. The air at atmospheric pressure inside this bell is then enclosed, and the sewage, continuing to rise outside and above the rim of the bell, compresses the enclosed air sufficiently to lift the bell, spindle, &c., which opens the compressed-air admission valve E. The compressed air thus automatically admitted into the ejector presses on the surface of the sewage, driving the whole of the contents before it through the bell-mouthed opening at the bottom, and through the outlet pipe B into the sewage rising main or high-level gravitating sewer, as the case may be. The sewage can only escape from the ejector by the outlet pipe, as the instant the air pressure is admitted on to the surface of the fluid the valve on the inlet pipe A falls on its seat and prevents the fluid escaping in that direction. The fluid passes out of the ejector until its level therein reaches the cup C, and, still continuing to lower, leaves the cup full until the weight of the liquid in the portion of cup thus exposed and unsupported by the surrounding water is sufficient to pull down the bell and spindle, thereby reversing the compressed-air admission valve, which first cuts off the supply of compressed air to the ejector and then allows the air within the ejector to exhaust down to atmospheric pressure. The outlet valve then falls on its seat, retaining the liquid in the sewage rising main, and the sewage flows into the ejector through the inlet once more, driving the free air before it, through the air valve, as the sewage rises; and so the action goes on as long as there is sewage to flow. The positions of the cup-and-bell floats are so adjusted that the compressed air is not admitted to the ejector until it is full of sewage, and the air is not allowed to exhaust until the ejector is emptied down to the discharge level. The compressed air for

actuating the ejector is produced at a central station, and is conveyed in iron pipes laid under the streets to the several ejector stations, as already explained. The Shone ejectors at Erith were supplied, and the air mains laid, by Messrs. Hughes and Lancaster.

MESSRS. FRASER AND CHALMERS' WORKS.

These works have been in operation for about ten years, and are well equipped with modern tools and appliances. The manufactures carried on are gold and silver mining machinery, hoisting and pumping engines. Riedler patent mechanically-controlled valves for pumps and air compressors. The iron foundry is 220ft. long by 150ft. wide, and has four bays; the two centre ones are each of 50ft. span, and the sides 25ft. span. The centre bays are served with three travelling cranes of 5, 15, and 25 tons capacity, also four hydraulic cranes of 3 and 5 tons capacity. Besides the three large core ovens of 4000 cubic feet capacity each, there is installed the Piflin portable stove, by which the largest moulds are dried on the floor at less cost than by the old method of fixed core ovens.

The boiler shop measures 220ft. by 120ft., and consists of three bays. The centre bay is of 60ft. span, and is served with a 25-ton power-driven travelling crane. The side bays contain shears, punching and planing machines, and are served with jib cranes.

The wood-working shop is a two-storey building, 120ft. by 60ft., and has a lumber shed adjoining, 220ft. long. These shops contain the most modern wood-working tools suitable for getting out stamp mill frames and other work required in stamp mill practice. The upper floor is the pattern shop, which is also supplied with suitable wood-working machines. The blacksmith's shop is 140ft. by 60ft., and is equipped with four steam hammers, and band and circular saws. One end of this building is fitted up as a polishing shop, where all the work is polished before being shipped.

The machine and fitting shop is 440ft. long by 110ft. wide. One end, 180ft. long, has a centre bay 50ft. wide, served with two travelling cranes of 20 tons capacity, 24ft. high above the floor. Side bays, 25ft. wide, are served with hand-travelling cranes of 5 tons capacity. The centre part of the building, 200ft. long, contains four bays. This part of the shop is occupied by lathes, planers, and other iron-working tools, and most of the machining is done here, the hand fitting being done in the side bays in the part first referred to. The last 60ft. is an erecting shop, which is served with an electric crane of 25 tons capacity, and an auxiliary 5-ton hoist on the same trolley as the main hoist. In this shop is a pit 80ft. long by 20ft. wide and 8ft. deep, covered with a removable floor, so that in erecting vertical engines there is a vertical height under the crane of 45ft.

The works are connected by rail with the South-Eastern Railway, and cars can be loaded direct from the machine-shop cranes. Machinery can also be shipped by barge to the London Docks, the works having wharf facilities, and a loading crane that will handle any machinery that is shipped that way.

ASSOCIATION OF MUNICIPAL AND COUNTY ENGINEERS.

THE following have been elected as the new Council:—President, Mr. E. George Mawbey (Borough Surveyor, Leicester); vice-presidents: Messrs. J. P. Barber, W. Weaver, and T. H. Yabbicom; ordinary members of Council, Messrs. W. N. Blair, A. E. Collins, A. Creer, A. T. Davis, A. D. Greatorex, E. P. Hooley, A. B. Macdonald, J. Paton, S. S. Platt, J. Price, H. T. Wakelam, and C. F. Wike; hon. secretary, Mr. C. Jones; hon treasurer, Mr. Lewis Angell.

MUNICIPAL OFFICERS' ASSOCIATION.

THE SUPERANNUATION BILL.

THE members of this Association were favoured with brilliant weather on the occasion of a district meeting which was held at Tunbridge Wells on Saturday last. Most of the members journeyed down from Charing-cross in specially-reserved carriages. They were received at the Town Hall at 11 o'clock by the Mayor of Tunbridge Wells, the Clerk, Mr. W. C. Cripps, and the chief officers of the Corporation, and after an address of welcome from the Mayor the party paid a visit to the various municipal establishments, including the Telephone Exchange and switch-room, the Public Baths, the Electricity Works, and the Grosvenor Recreation Ground. This tour of inspection having been concluded, an adjournment was made to the Clarendon Hotel for luncheon.

Mr. C. W. TAGG (Camberwell), who presided, proposed the health of "The King and Queen," and afterwards asked the company to drink to the cause. Both toasts were heartily received. In the course of a short speech he said they were glad to have an opportunity of visiting the historical town of Tunbridge Wells, and he expressed a hope that all the municipal officers in the district would join the Association. Mr. H. JONES (Kensington) gave "The Chairman," and Mr. TAGG briefly replied.

The afternoon was spent in visiting the Corporation waterworks at Pembury and the famous High Rocks. On returning, the members were entertained at tea by Mr. W. C. Cripps, the Town Clerk, at his residence, "The Lawns," Camden Park.

In the evening a meeting was held at the Town Hall, Mr. J. Wilson (Croydon) presiding, in the unavoidable absence of Mr. G. L. Gomme (London County Council), the president of the Association.

The MAYOR OF TUNBRIDGE WELLS, in an address, said he hoped that they had been able to spend a pleasant day. Commenting upon the rapid growth of the borough, he mentioned that they had taken up many enterprises, including the waterworks, the local telephone service, and the baths. Their telephone system, which would shortly be complete, was, he ventured to think, one of the best in the country.

The TOWN CLERK explained that Tunbridge Wells had been able to go in for municipal trading to a larger extent than many larger boroughs, because it had the advantages of a large rateable value.

Mr. J. WILSON (Croydon), in the chair, expressed his appreciation of the kindness they had received at the hands of the Mayor and officials of the Corporation.

After some business of a formal character had been disposed of,

Mr. WILSON made a few remarks on matters of interest to the Association. There were other objects for which it existed besides the obtaining of superannuation, although that was the thing to which they were turning their energy at present. The Association had been brought into existence to safeguard the interests of municipal officers, and this function it had performed faithfully. The speaker next went on to refer to the excellent qualities of their president (Mr. Gomme) and to the many concessions which the Association had been able to get for members. The time might also come when they would have a benevolent orphan fund.

Mr. TAGG (Camberwell) next spoke on the superannuation question, making reference to the future policy of the Association, as to the most desirable form of Bill to promote, viz., compulsory, adoptive, or permissive. What they had to look at, said Mr. Tagg, was which was the best means of obtaining what they desired. Should it be compulsory, adoptive, or permissive? He reviewed the history of the whole question at some length, explaining that the Poor Law

Officers' Superannuation Act had not been an unmixed blessing to municipal officers, as many of the highly-paid officials under the Poor Law had been the first to take advantage of the measure, and this had set many Local Authorities against superannuation. Then, again, the Association of Municipal Corporations were opposed to. Under these circumstances he thought that the only solution to the question was by getting an adoptive Act passed. Such an Act would not take away the power of the Local Authority, and would be much easier to get through Parliament. No Government, be it Liberal or Conservative, no matter how strong its majority, could pass a Bill like the one the Association had at present drawn up; and he advocated that the Association should run an adoptive Act next session.

Mr. KEEN (Hammersmith) moved that the Executive Council should be instructed to draw up a Bill on the lines suggested by Mr. Tagg.

Mr. J. EARWICKER (Croydon) seconded.

Mr. C. J. F. CARNELL (Sevenoaks) did not agree with the principle of an adoptive Act, but thought that it should be compulsory, and that the contributions should be paid into a central fund.

Mr. CARNELL (Camberwell), who also spoke in favour of a compulsory measure, urged the Association not to come to a hasty decision.

Mr. JONES (Kensington) deprecated the change of tactics. It appeared they were dropping superannuation altogether by this new policy of Mr. Tagg's. If they were entitled to superannuation they should go through until they got it. He did not favour an adoptive measure of any description.

At this juncture, Mr. TAGG suggested that the resolution should be withdrawn in favour of a simple reference of the matter to the Executive Council.

This was agreed to, and the usual vote of thanks brought the meeting to a close.

CORRESPONDENCE.

(*To the Editor of* THE SANITARY RECORD.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

SCAVENGING IN CAPE TOWN.

SIR,—Adverting to a paragraph which appeared in your worthy journal on April 25th, 1901, it may interest you to hear that the police without any warning decided to prosecute persons placing refuse tins on the side of the streets, for the convenient removal of the same by the scavenging carts—which practice obtains in the best regulated towns in England—and among the few that were prosecuted, my maid was one. The tin contained innocuous paper, leaves, and street dust deposited in my garden during a severe gale, and it was placed close to the gate. The case was not defended, as, doubtless, under the present circumstances, it might be wrongly interpreted.

Credit is due to the police for taking such energetic action; but it may be interesting to note that we do not hear of further prosecutions, although "one might express surprise at the lax examples" to be seen daily.—Yours faithfully,

R. O. WYNNE ROBERTS,
City Engineer.

Town House, Cape Town,
Cape of Good Hope,
May 28th, 1901.

SANITAS SANITATUM OMNIA SANITAS.

WE have received the following letter on the above:—

G. CECIL DICKSON, Esq., Medical Officer of Health, Carnoustie, writes:—"In answer to Query 2220 (June 6th), I enclose extract of speech from that interesting book, 'The Wit and Wisdom of Beaconsfield.' So the policy of sewage goes back a good many years:—Speech by Disraeli at Aylesbury Royal and Central Bucks Association, September 21st, 1864: 'A very great scholar observes that in his opinion the declaration of the wisest of mankind—"Vanity of vanities, all is vanity"—was not a misprint but a mistake of the copyist, and that he believed the words were not "Vanitas vanitatum omnia vanitas" but "Sanitas sanitatum omnia sanitas." Now I quite agree that it must have been a misquotation of the wise King of Israel, and if so that they would have constituted one of his best claims to be considered the wisest of mankind.'"

P. TARGETT ADAMS, Esq., Medical Department of the General Post-office, also writes:—In reply to your correspondent in Query 2220, "*Sanitas Sanitatum omnia Sanitas*," I fear I am unable to answer his query as to whether the late Lord Beaconsfield paraphrased the old epitaph from which it is undoubtedly derived, viz.: "*Vanitas Vanitatum omnia Vanitas*," which may be seen in the engravings of the famous Thomas Bewick; as, for instance, on page 202 of the first edition of "British Birds." It is a favourite quotation of those ignorant and obstructive persons, opposed to sanitary reform of any kind whatsoever, and quite improbable (at least with this interpretation) as coming from one blessed with so much sound common sense as the late lord referred to; although it is possible he may have used the phrase with a widely different meaning from that with which I have heard it so often associated.

THE PLUMBERS' COMPANY.

A DISTRIBUTION of Certificates of Registration to some 200 master and operative plumbers was held at the Guildhall this week.

Attention was called by the Master of the Plumbers' Company to the indenture of apprenticeship for plumbers in London, framed by the Plumbers' Apprenticeship Board, containing covenants providing that the apprentice should attend and diligently study at such classes of any technical institution or trade school now or hereafter to be established in London as approved by the Board. The instruction to be in sanitary plumbing and in the practice of the plumber's art, and the apprentice to present himself for such examinations in technical knowledge and workmanship as may from time to time be prescribed for the purpose of the National Registration of Plumbers.

Leith.—The annual report of the Sanitary Inspector for Leith, Mr. George Alexander, has been issued, and shows that under the Public Health and Burgh Police Acts 887 complaints were received, exclusive of those in which no action fell to be taken by the Department and those relating to dirty staircases. Rat-infested houses caused some of the complaints, the grounds of which were removed, while the total number of inspections made in regard to nuisances was 6553. There were seven common lodging-houses, with registered accommodation for 919 lodgers. At the public slaughter-house 10,733 animals were slaughtered, of which 84 were condemned, 49 being found to be suffering from tuberculosis. With regard to the cemeteries a preliminary inspection of South Leith parish churchyard disclosed the fact that the public portion is nearly full, but before any definite report can be issued a more exhaustive examination will require to be made.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

JUNE 20, 1901.

THE MILK STANDARD.

THE decision of the Board of Agriculture with reference to the Milk Standard has now been announced. In reply to questions on the subject in the House of Commons last week, Mr. Hanbury stated that, after carefully considering the evidence submitted to the Departmental Committee and their reports, he proposed to fix a standard under which, for the purposes of the Food and Drugs Acts, a presumption would be raised that milk was not genuine unless it contained 3 per cent. of milk fat, and 8·5 per cent. of non-fatty milk solids. Regulations to this effect were being prepared, and he proposed that they should come into effect on 1st August. It will be remembered that the majority report recommended a standard of 3·25 per cent. of fat. The minority report (Mr. Barham's) recommended that from March to June inclusive, the standard of fat should be fixed at 2·75, and for the remaining eight months of the year at 3 per cent. The standard fixed is of the nature of a compromise between the two. With every desire to secure a high standard for our milk supply, it must be confessed that there are undoubted difficulties with regard to the adoption of the standard recommended in the majority report. There has been a great outcry in the dairy trade that such a standard is an impossible one, in view of the great variations in the quality of the milk, which is influenced by such causes as the individuality of the cow, the period of lactation, the season of the year, the food she was consuming, the temperature or climatic causes, and the like. On the one hand there is the danger that with too vigorous a standard, genuine milk, though of poor quality, might be condemned; and, on the other, that with too low a standard the door would be opened to fraud. In illustration of some of these difficulties, we may refer to some figures which were given at the Congress of the British Dairy Farmers' Association the other day. At that Congress one gentleman, Mr. Allesbrook, Wollaton, gave the results of three analyses of milk taken from the same lot of cows under the same conditions, the first of which, from the morning milk, only showed 2·75 per cent. of butter fat, while the evening milk yielded 5 per cent., and another morning's milk gave no more than 2·8 per cent. These figures were seriously questioned by Mr. John Hunter, the Edinburgh analyst, who, speaking from the experience of forty years in the analysis of milk, did not think so great a variation possible between the morning and evening milk of any one herd of cows, if the whole milk was taken; but Mr. Allesbrook replied that the analyses he gave were made by the City Analyst of Nottingham, and, as a producer and seller of milk of forty years, he thought the results were just what might be expected. So far is it possible for experts to differ! An almost identical case of wide variation was given by another gentleman from Bristol. A rather significant fact was mentioned, in this connection, by Dr. Drinkwater, another analyst of experience. He found from his note-book, he said, that during the last fifteen years there had not been a single prosecution for afternoon milk, the Inspectors invariably taking the morning milk for their analyses. Keeping all these facts in view, we think the dairy trade should be fairly well satisfied with the Department's decision, for it will be observed that it does not propose to introduce a cast iron standard with an inflexible limit: it simply establishes a *presumption* of adulteration in cases below the 3 per cent., which may, of course, be overcome by satisfactory proof that the milk in any particular case is actually genuine.

The New Factories Bill.

The discussion on the second reading of the Bill brought forward by the Home-office for the amendment of the Factory and Workshops Acts was on the whole extremely friendly and favourable. The Bill was well received. For the moment the air was cleared of party spirit, and the one desire animating all sections of the House appeared to be to make the Bill a really useful and serviceable measure. It was criticised in some quarters as not going quite far enough, and some of its provisions will doubtless be subject to modification or enlargement in Committee, but the general consensus of opinion was that it marked a large advance on the Bill of last year, and would effect a great improvement on the existing law. An amending Bill such as this one is so full of detail, and deals with such a variety of subjects, that it is impossible in the present notice to traverse it except in its most salient features, more particular criticism being reserved till the Committee stage, when it can be examined clause by clause. Let it suffice, therefore, to say that its more exclusively sanitary provisions are excellent in scope, and aim at changes in the law which were much needed—such, for example, as that dealing with the ventilation of workrooms. The Home Secretary, in explaining the provision, remarked that there were many cases in which girls were crowded together in rooms heated by gas jets, the faint noxious fumes of which were practically never changed. Precisely such a case occurred not long ago, and was reported at the time in this journal, in which the Bench, though sensible of the justice of the complaint, was powerless to convict, as the existing law was not sufficiently wide. Under this Bill it will be required that in all such places there must be sufficient ventilation. Another useful provision of the Bill relates to bakehouses, following the precedent of the London Public Health Act, 1891, and provides that all places where the floor of the room is 3ft. below the surface of the ground should be considered underground. In such cases the Local Authority is charged with the duty of seeing that they are sanitary and in other respects suitable for the trade carried on there. Then a number of works and industries, hitherto exempt, are to be brought within the operation of the Acts—such as electrical and cognate works, and the processes of fruit-preserving and fish-curing. With regard to these latter, there will be some relaxation during the busier seasons of the year, so far as the question of hours is concerned; but in all questions of sanitary administration they will be brought under the Acts. One of the most important features of the Bill is that laundries are now definitely to be scheduled as workshops, and religious and charitable institutions, where laundry work is carried on, are not to be excluded. The Home Secretary, however, indicated that there would be some modifications as to the inspection of such institutions, the nature of which would appear more fully in Committee. On this point there is certain to be controversy; but, in the meantime, it is well to reserve criticism. We shall watch the progress and further development of the measure with much interest, in the expectation that it will be shaped into a most useful piece of legislation.

Unqualified Pharmaceutical Assistants in Scotland.

The summer session of the General Medical Council contained, in its roll of disciplinary cases, one which raised a question affecting a considerable proportion of the profession, at least in the West of Scotland. A doctor was charged with having habitually employed as assistants for the sale of drugs and poisons persons who were not duly qualified, thereby causing them to commit breaches of the Pharmacy Acts. They had, under cover of his professional qualifications, sold scheduled poisons to the public, from which lamentable consequences had resulted. No penal action was taken in regard to the case, in respect that the case was the first of the kind, and that the accused practitioner assured the Council that he would in future carefully avoid any similar ground of complaint. The case, however, has raised a strong feeling among the doctors in Glasgow and the West of Scotland, who seem to consider that the decision of the Council establishes a precedent which will deprive them of their right to sell drugs and poisons. Whatever may have been the case in other parts of the country, it has, we understand, been the practice in the West of Scotland for hundreds of years for doctors to conduct dispensaries or druggists' shops in connection with their practices. In the old days, we are informed, it was the universal custom for practitioners to begin their practice in shops. The action of the General Medical Council will, it is believed, have the effect of striking at this long-established usage. Accordingly, at a public meeting of medical practitioners held in Glasgow recently, it was resolved to memorialise the General Medical Council on the subject. In the memorial, which was signed by 400 practitioners, it was pointed out that it was impossible to teach the business of dispensing without employing unqualified assistants, and it was contended that to subject registered medical practitioners to the risk of being struck off the register because a salesman of theirs sold drugs or poisons was unauthorised by Act of Parliament. A deputation was also appointed to wait upon the Council in support of the Memorial. The Medical Council, however, refused to receive the deputation. The practice in question, it held, was one fraught with danger to the public. The sequel was somewhat singular. The members of the deputation lodged a formal protest against the action of the General Medical Council in refusing to accept the memorial, and to hear the deputation in its support.

Waterworks Engineers.

We have pleasure in calling attention to the sixth annual meeting of the British Association of Waterworks Engineers, which takes place at Birkenhead in the second week of July. Though one of the youngest of the

engineering societies, the Association has made good progress, and the interest it has aroused in the ranks of those belonging to this special branch of public service, has more than justified the hopes of its founder. Nothing but good can come out of the specialisation of the different branches of engineering, and until the above-named Association was established, the peculiar features of waterworks construction and maintenance had not received the attention they deserved. At the forthcoming meeting, Mr. W. A. Richardson, M. Inst. C.E., Waterworks Engineer to the Birkenhead Corporation, will be the President, and in the course of his inaugural address he will give some interesting details concerning the local water supply. Papers will be contributed by Mr. William Ingham, Torquay; Mr. Wm. Watts, past president (who will deal with the important subject of "The Pollution of Public Water Supplies"); and Mr. A. G. Cloake, London. In addition there will be a lecture by Mr. William E. Plummer, M.A., F.R.A.S., on "Rainfall, the Cycle of Precipitation." Compared with the programme set for most annual meetings of scientific societies this list is exceedingly brief, but we think the curtailment is wise. Far better to have two or three good papers and let them be well discussed, than have a number of mediocre contributions which neither add dignity to the proceedings nor to the reputation of the contributors. There will be quite a number of excursions; not only will the surrounding waterworks be visited, but Laird's Shipbuilding Works, the Mersey Tunnel Pumping Station, the Liverpool and Birkenhead Docks and Observatory, and Port Sunlight. Altogether the meeting promises to be the most successful yet held.

Municipal Fire Insurance.

Some time ago our esteemed contributor "Senex" indicated that a movement was in progress to secure the establishment of a scheme of municipal fire insurance. A few districts have for years followed the example of the great shipping companies, and have created a special fund to insure the property of the municipality, and such cases have worked well. The present time appears to be favourable for such a plan to be introduced into the metropolis. Lately a Committee of the London County Council has been giving special attention to the expenditure on the administration of the Fire Brigade, and the question of insurance has been included. The report of the Committee was presented last Tuesday, and in which it was stated that, "As the result of a careful consideration of all the facts, we have come to the conclusion that it is desirable that the Council should become its own insurer of its property against fire, and that the scheme formulated to give effect to this should be so drawn as to admit of all London Local Authorities entering into the scheme if and when they choose to do so. We believe that sooner or later many of these Authorities will associate themselves with the Council in this matter, especially if the Council be able to offer such Authorities a reduction of the premiums now paid. To this point we have necessarily devoted a good deal of attention, and we are convinced that the Council may with safety offer a rebate of 25 per cent. from the current rates of premium now charged by the tariff offices. We propose that, in the event of any deficiency arising on the fund, the Council should have authority to borrow on the security of the rates, repaying any sum so borrowed within a limited period. We think, however, that after a few years the fund would accumulate to a figure which would render a deficiency improbable." The suggestion is a thoroughly practical one, and might be carried out at a minimum of cost. The combination of all the metropolitan boroughs would make it an assured success.

A Fair Rent Court.

We have from time to time, in dealing with the so-called housing question, insisted that the vital matter for the people was not so much a question of accommodation as of rent. The workers have just cause to complain of the inordinate demands made upon their limited incomes by the owners of small property, and until something is done to give the tenant a security against these ever-increasing advances, anything like a satisfactory settlement will be impossible. We know that some people assert that low rents are impracticable because of the greatly-increased cost of building operations. But to this we reply that many of the most glaring rack-rents are not on new property, but on that which has been in existence for several years. We have before us instances of how rent has been raised within the past ten years. The cases quoted are from the suburbs, for increasing rents are by no means confined to the metropolis. For property letting in 1892 at 6s. per week, 10s. and more is now being asked. Nothing has been done to improve the houses, and the rates are but little higher now than they were under the lower rent. Another case is a house which had been less than £20 rent for years, where, on a new tenant coming in, it was increased about 30 per cent., and the landlord refused to do the house up, although nothing had been done to it by him for at least seven years. What we contend is that if the lower rent pays a fair return to the owner the tenant should have some security that that rent should be preserved to him, and that he shall not be compelled to choose between disturbance or accepting periodical increases. We know this doctrine may not be political economy, but we believe that it is justice and equity. And it is because of this belief that we are glad to see an effort is to be made to establish a fair rent court for London. Mr. Steadman has given notice to the London County Council of his intention to move:—"That in consequence of the growing increase in rents, it be an instruction to the Parliamentary Committee to prepare and insert a clause in the next General Powers Bill giving the Council the power to establish fair rent courts within the whole of the County of London."

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

In my notes of last week I adverted to certain statements which had been published by a so-called "Expert" adverse to the modern (*i.e.*, bacteriological) systems of sewage disposal, and who asserted that such systems were absolutely dead. It will be of especial interest to my readers to know that another "expert," Professor W. H. Perkin, of Owens College, Manchester, has also been giving his opinion on these systems before the Royal Commission on Salmon Fisheries as to the prevention of the pollution of rivers by sewage and trade effluents. Now, Professor Perkin happens to have no special interest in any particular system, than that of satisfying himself, as a chemist of very considerable repute, as to the one which is most efficient, and this is what he says:—

Briefly the bacterial treatment of sewage and other liquids consisted in exposing them under regulated conditions to the natural agencies which everywhere brought about the decomposition of organic matter, and its final conversion into harmless inorganic forms. The purification of sewage by land was dependent on the same bacterial activities as are at work on the other systems, but the amount that could be treated is very much less in the case of land treatment (area for area), so that in many cases it is impossible.

The sewage of Manchester contained almost every imaginable kind of trade effluent, and the results obtained by its final treatment had been quite satisfactory. Certain exceptions, such as the greasy refuse from wool scouring, would probably have to be dealt with by the manufacturers before admission to the sewers: and he believed the recovery of the grease would be very profitable to the manufacturer. So far the bacterial process had been marked with entirely satisfactory results. Accrington is treating the whole of its sewage with open septic tanks and continuous filters. Manchester, Oldham, Leicester, Sheffield, Yeovil, Exeter, and many other places have schemes for treating the whole of their sewage by bacterial methods. Bradford, and Leeds, and Rochdale are faced with the wool scouring difficulty, but they all have bacterial methods in contemplation. In his opinion the system had been so successful that all towns should be compelled to adopt the treatment. If this were done there was every reason to believe that the rivers would be rapidly cleansed and able to support fish life.

This opinion is one which is in strict keeping with that which has been consistently put forward by me in this column from time to time, and is the one also held by all who have investigated the subject.

It betokens a healthy condition of sanitary administration when we see Medical Officers of Health vieing with municipal Surveyors, as they are now endeavouring to do, especially in the metropolis, to secure the responsibility of supervision over structural work appertaining to dwelling-houses. Just now, as will be seen from a report which appeared on page 446 of this journal, Medical Officers are agitating for the supervision of drainage work—both as regards old and new buildings—to be placed under their department. On this subject I have a communication from a Municipal Surveyor, who hints that some Medical Officers hold a high opinion of their own capabilities as engineers and architects, and inquires how medical men can be assumed to have acquired a practical knowledge of structural work, and asks if any Medical Officer could prove his fitness for the responsible position of drainage engineer by taking levels and preparing plans, specifications, and quantities for the drainage of a town house, and asserts that if he could not do this he should not be placed in the false position of acting as a referee on plans and schemes submitted by architects and surveyors for approval to Local Authorities.

I am afraid I cannot agree with all my correspondent's strictures regarding our medical friends. There is ample scope for the latter in most matters pertaining to public health, and they have been of great service in the past, and will, I know, continue to give such in the future to the gain of the community. Municipal Engineers and Medical Officers of Health can and should work together for the common good each within his own particular sphere, and there are abundant opportunities both for the prosecution of measures which tend to the improvement of our dwellings and the artificial conditions under which we are compelled to live in cities and towns.

While it may be urged that the Medical Officer's department should have the power to examine and certify for drainage of new buildings, so that dual control should be avoided, I would point out that such bodies as the Royal Institute of British Architects would offer strong and powerful opposition to such a course. In fact, they are now seeking to have diverted from the Medical Officers' department the responsibility for supervision of alterations of drainage to old houses. As I personally know the opinions of numerous members of the Institute, it is no secret for me to explain that they hold that the Surveyor is like themselves, a practical man who is enabled to discuss with them practical requirements and difficulties, and who is, it is said, rarely a faddist. Their opinion may be right or wrong, but I fear the Medical Officer will find this opposition unsurmountable.

Senex.

Sanitary Inspectors' Associations.

NATIONAL UNION.

The annual meeting of the National Union of Sanitary Inspectors (Midland Centre) took place at Tamworth on Saturday last. There was a representative attendance, including Messrs. W. H. Coney, chairman (Wednesbury), H. H. Spears, general hon. secretary (West Bromwich), John Peers, district hon. secretary (Chief Inspector, Wolverhampton), and representatives from Manchester, Wolverhampton, Sedgley, Siesdon, Coseley, Birmingham, Bescot and Walsall, Leamington Spa, Short Heath, Walsall, Tamworth, Atherstone, and Nuneaton. The party visited Tamworth Castle and Drayton Manor during the afternoon, after which they adjourned to Millfield House, Tamworth, where they were entertained by Mr. H. J. Clarson, C.E., the Borough Surveyor. Subsequently a meeting was held in the open air, Mr. W. H. Coney presiding. The annual report, which was adopted, showed that the progress of the Union was well maintained, the membership numbering ninety-six. Votes of thanks were passed to the retiring officers. Dr. Reid, Staffordshire county Medical Officer, was unanimously re-elected president for the year, and Dr. H. Malet, Medical Officer of Health, Wolverhampton, was elected vice-president of the Centre. Mr. Clarson, in acknowledging a vote of thanks, said he was pleased to notice an improvement in regard to the pollution of the Tame, and expressed a hope that it would continue, the river being in a better condition now than he had seen it for the last fifteen years.

Public Works.

SEWERAGE.

An inquiry is to be held at Folkestone into an application for sanction to borrow £1000 for works of sewerage.

The Quorndon Urban District Council has passed plans for the sewerage of its district. The scheme is estimated to cost £11,000.

A local inquiry was held last week with reference to a proposal of the Rural District Council of Tewkesbury to borrow £2220 for the sewerage of Kemerton.

A Local Government Board inquiry has been held at Alvaston into the application of the Urban District Council for sanction to a loan of £2000 for sewage disposal works.

Mr. H. P. Boulnois has held an inquiry at Great Sutton into an application by the Wirral Rural District Council for powers to borrow £2900 for sewerage works in the township.

The sewage purification works constructed by the Morley Town Council at a cost of £43,826, were formally opened on Monday in last week by the Mayor, Mr. Councillor C. Scarth.

The Town Chamberlain reported, at a recent meeting of the Glasgow Town Council, that from 1895-96 to date the sum of £27,557 had been spent upon the new drainage scheme.

The Willington Quay District Council has agreed to apply to the Local Government Board for permission to borrow £1360 for the purposes of defraying the cost of a new sewer and repairing streets, &c.

The Walton Urban District Council has decided to make application to the Public Works Commissioners for £4000, being the second instalment of the loan of £8200 in connection with the main sewerage scheme.

The Sewage Disposal Committee of the Failsworth District Council recommends the acceptance of the tender of Mr. H. E. Buckly, of Bingley, amounting to £1739 6s. 8d., for land filtration works at the outfall works.

A Local Government Board inquiry has been held at South Dublin relative to the application of the Rural District Council for a loan of £330 for the purpose of constructing sewerage works at Seaview-terrace, Donnybrook, the area of charge to be the rural district.

The last report of the Irwell and Mersey Joint Board showed the effluent of the Urmston and Flixton joint sewage farm to be the best out of twenty-six effluents analysed. It has been decided to construct an additional bacteria bed the same size as the present one to allow more room for storm overflow. The engineer has been instructed to prepare plans, which will also include sewer extension in Moorside-road.

The Dean of Norwich has made the following communication to the Press:—"There is not in Switzerland a centre of exercise which has grown so rapidly in dimension and in popularity as Zermatt. Twenty years ago there were but two large hotels. There are now over twenty. The drainage of what may be called, in the height of the season the town, has become a serious problem to all concerned. From time to time suspicion has been aroused as to the insanitary condition of the village. The hotel proprietors, under the lead of Herr Alexandre Seiler, have made up their minds to cope with what was becoming an increasing difficulty. They have formed themselves into a syndicate to provide the capital necessary for the introduction of drains on the most approved method. The winter was given to extensive preparation, and with the arrival of spring Zermatt was opened up and huge drains were laid, while connections were formed with other smaller drains from each of the side streets. The system runs down to the Viége-Zermatt Station; it passes thence alongside the Zermatt-Gornergrat line, and into the river Visp at one of its most rapid points. Water from the Trift-thal is kept perpetually running through the system, and from such a height the flush will be quite effective. Notwithstanding the severity of the winter, the lateness of the spring, and the magnitude of the work, it will be completed in the early summer. Two other improvements have been made. A huge reservoir has been constructed up the Trift, which supplies the hotels, fountains, fire, and irrigation pipes, and the vexatious cobstone in the central highway has given place to a smooth pavement."

WATER.

The Mumbles Water Company have under consideration a scheme to construct a new reservoir and filter beds at a cost of from £3000 to £4000.

Operations have been commenced at Bowfield in connection with the laying of a third pipe from Rowbank Reservoir to Stanley Dam, near Paisley. The contractor on the Howwood section is Mr. John Sproull, Sawmillfield-street, Glasgow.

Owing to the continuance of dry weather the Glasgow water engineer has written to the superintendent of cleansing asking that the use of water for street washing and watering purposes be, if possible, restricted, as the reservoirs are going down rapidly.

A petition on behalf of Mr. Edward Thomas and others, praying to be heard by counsel against the Llandrindod Wells Urban District Council's Water Bill when the Committee stage is reached, has been deposited in the Private Bill-office of the House of Lords. The Bill has already been passed by the House of Commons.

At last week's meeting of the St. Helen's Water Committee, Mr. Lackland, engineer, reported that he had prepared plans of the storage reservoir to be constructed at Brownedge, near the softening works, at a cost of £30,000, to hold 10,000,000 gallons. The plans were approved, and ordered to be sent to the Local Government Board, to whom application has been made to borrow the necessary money.

Mr. J. T. Wood presided at the meeting of the Water Committee of the City Council last week, when the water engineer reported on the distribution of water for the weeks ending June 1st and 8th, and for the corresponding weeks last year. The total quantity supplied, both within and outside the compulsory limits, was—Week ending June 1st, 188,761,000 gallons; average per day, 26,966,000 gallons. Week ending June 8th, 205,495,000 gallons; average, 29,356,000 gallons. For the corresponding weeks, the averages per day were 27,140,000 gallons and 27,003,000 gallons

At the last monthly meeting of the Newport County Council, Mr. Williams grew insistent as to when the report as to the ultimate cost of the Wentwood water undertaking would be presented. The total payments up to date amounted to £263,633 4s. 6d. The Town Clerk said Mr. Baldwin Latham was too busily engaged in parliamentary work just now to prepare the expected report. Mr. Little wanted to know how the present supply stood, as they are now in the dry season. The waterworks manager replied that there were 226,000,000 gallons in store, or about the same quantity as last year. The Mayor added that the water for street watering now came from outside sources.

Members of the Yeovil Town Council paid their customary visit of inspection to the source of the Yeovil water supply at Melbury last Thursday. The party left the borough in two brakes about half-past two o'clock. The first stop was at the new reservoir on Summerhouse Hill, which it was found contained about 750,000 gallons. A move was then made to the brakes again, and, notwithstanding the fact that the weather was far from summer-like, the drive to Melbury was enjoyed by all. Stockwood Spring was first visited, and here a plentiful supply of water was found. Haydon Wood Spring, from which it is proposed to augment the present supply, was also flowing satisfactorily, and Spring Pond, from which the existing mains are laid, was found to be yielding freely. The Borough Surveyor acted as cicerone, and fully explained the levels of the springs, their yield, &c. Adjoining Spring Pond a cold luncheon was partaken of, following which a few complimentary toasts were honoured; and about half-past seven a start was made for Yeovil, which was reached about an hour later. The visit proved both instructive and interesting, and but for unforeseen circumstances arising, consumers of water in the town may rest assured that there will be no curtailment of the supply in the immediate future at all events.

At a recent meeting of the Waterworks Committee of the Manchester City Council tenders were dealt with for the supply of iron pipes for the completion of the second pipe from Thirlmere to Manchester. The total quantity to be used is about 62,700 tons. The cost is estimated at about £314,000. The City Council gave instructions to the Committee some twelve months ago to proceed with the work. Since that time there has been a decline in the iron market, and a large sum in the estimated outlay has probably been saved.

The Local Government Board has written the Cowlyd Water Board sanctioning the Board's application for powers to obtain a loan of £2651, but reminding the Board that certain particulars respecting former financial transactions of the Board had not yet been supplied. The Clerk and Engineer were directed to supply the required particulars, and the Clerk was directed to obtain the money from the Public Works Loans Board. Mr. Bevan moved that a committee of five members be appointed to consult with Mr. R. S. Chamberlain, solicitor, and Mr. Farrington, C.E., and report on the advisability of procuring an Act of Parliament or Provisional Order to enable the Board to undertake the necessary works and to make such regulations as to secure a constant supply of water to the outlying districts under the Board's control. The resolution was adopted.

The Malton Rural District Council had before it on Saturday last an important question of water supply to several villages, including Slingsby and the "street villages" between that place and Malton. The Council had just reached the point of sanctioning a scheme of getting water from a reservoir at Gilling when Lady Carlisle showed that that scheme would cost £8400, and entail a rate of 1s. 7½d. in the pound, whereas one that she suggested, for getting a supply from springs on the Castle Howard estate, would only cost £4800, and the rate would only be about 9d. in the pound. Her Ladyship also observed that Slingsby and Fryston could not be forced into the dearer scheme, as they could get a plentiful supply by gravitation at a much cheaper rate. Lady Carlisle moved that the whole subject be referred to a new committee to consider the Gilling scheme as compared with others, and this was adopted.

At a recent meeting of the Northam Council, Mr. Baldwin Latham, civil engineer, estimated that £10,000 would be required for the completion of the Northam Waterworks, and the Clerk pointed out that to this £1547 had to be added for land. Mr. Lard stated that of the last £7000 borrowed, the Council only had £2400 left, and it was decided to write to the Prudential Assurance Company to see on what terms they would allow the Council to borrow a further £12,000. In reply to the Council's communication to Dart and Pollard, with regard to their delay in the completion of the waterworks, they wrote stating that had the Council not delayed so long in sanctioning the extra £1000, and in completion of the supplemental contract for the same, the work would have now been completed. They hoped the Council would now grant a further time. Mr. Gerrard said the contractors had been laying pipe at the rate of a mile per month, and the Clerk read a letter from Mr. Latham, stating that the Council ought not to grant an extension unless the contractors pay all extra costs. It was decided that Mr. Latham meet the Council and consider the matter.

The case in support of the Stockport Water Bill, by which the Corporation of Stockport seek powers to obtain an additional supply of water from the Hayfield district, was concluded last week, after which evidence was called for the petitioners, the petition of the Grove Mill Paper Company being first heard. Mr. Alderman J. W. Southern, Manchester, one of the directors, stated that the owners had an undisputed right to make use of all the water passing through the river Goyt. It was proposed by this Bill to abstract two-thirds of the contents of the Sett and the Kinder, which fed that river and provided nearly half the total water passing the mill. Any diminution of the water supply would necessitate the increased use of steam power, and thus put the proprietors to extra cost. They therefore asked that in the event of its being found that, in spite of the compensation water proposed to be given, they were obliged to use more steam power at an extra cost, compensation should be given, the amount of the damages being assessed by arbitration.

The Knaresborough Rural District Council has decided to ask the Leeds Corporation if it will, if required, supply water to the village of Felliscliffe—through which the new pipe line will pass—on the same terms as the Harrogate Corporation is prepared to supply other parts of the Knaresborough Rural Council's area.

The resolution of St. Andrews District Committee refusing the petition of certain inhabitants in Leuchars to form a special water district for the supply of the village has roused some opposition, and an appeal against the Committee's decision has been intimated to the Sheriff. A special meeting of the District Committee was held at St. Andrews last week to consider what steps should be taken to defend the resolution of the Committee. On the motion of Provost Ritchie Welch, seconded by Colonel Erskine, chairman of the meeting, a small committee was appointed to instruct the solicitor to defend the case.

From the report which is issued by Mr. C. Perrin, water examiner, on the condition of the London water supply during April, it appears that the average daily supply delivered from the Thames during the month was 112,090,634 gallons; from the Lea, 50,996,200 gallons; from springs and wells, 28,081,508 gallons; from ponds at Hampstead and Highgate, 255,970 gallons. The last is used for non-domestic purposes only. The daily total was therefore 201,424,312 gallons for a population estimated at 6,206,251, representing a daily consumption per head of 32·45 gallons for all purposes. In the appendix to the report are given the results of the analyses undertaken by Dr. Thorpe, on behalf of the Local Government Board, and a communication by Sir W. Crookes and Professor James Dewar relating to the analyses made during April at the instance of the directors of the seven water companies.

LIGHTING.

The British Gas Light Company Bill has been read a second time in the House of Lords.

The Wolverhampton Town Council reports a loss of £130 on the year's working of the electric light.

The Local Government Board has sanctioned the borrowing by the Southend Town Council of £40,000 for electric lighting purposes.

The St. Helens Town Council has applied to the Local Government Board for sanction to borrow £16,500 for additional electric lighting plant.

The Darlington Town Council intends spending £14,000 for gasworks purposes, including the purchase of meters and stoves, and the laying of additional mains.

A Local Government Board inquiry has been held at Beckenham, with reference to the application of the Council to borrow £20,000 for the extension of the electric light.

At a recent meeting of the Whitehaven Town Council it was agreed to make an offer to the District Council to supply Parton with water at 6d. per thousand gallons, with a minimum payment of £100 per annum.

A Local Government Board inquiry has been held at Hoylake regarding an application by the Hoylake and West Kirkby District Council for permission to borrow £13,500 for the extension of electric lighting works and cables

A new gas light was introduced into Scarborough for the first time last week. The new machine is the patent of Mr. William Sugg. A lamp has been fitted with three of Mr. Sugg's new patent incandescent burners, which, by means of his machine, are supplied with high-pressure gas at 9in. (column of water). The consumption of the lamp is 30 cubic feet per hour, or 10 cubic feet each burner, and the light given is equal to 1000 candles. This result is obtained by raising the pressure of the gas ordinarily supplied by the gas company from, say, 2in. to 9in. pressure at the foot of the burner in the lamp by means of a small hydraulic ram, fixed in some convenient position to supply any number of lights. This ram is actuated by the water from the street main at a pressure of about 30 lb. to 60 lb. on the square inch. It is connected to a pump very much larger than itself, into which gas is taken from the service and forced up to the pressure required.

THE Notting-hill Electric Light Bill has been read a third time in the House of Commons.

AN inquiry was held at Newark last week with reference to the proposal of the Town Council to borrow £30,000 for electric lighting purposes.

THE Malvern Urban District Council has decided to borrow £17,000 for the installation of electric lighting and the erection of a refuse destructor.

AT a recent meeting of the Yarmouth Town Council it was stated that there was a deficiency of £751 on the past year on the electric light undertaking.

THE directors of the Commercial Gas Company notify that the price of gas will be reduced from 3s. to 2s. 8d. per 1000 cubic feet after this midsummer.

THE Shrewsbury Gas Bill, which has passed the House of Lords, came last week before Mr. Lowther (Chairman of Committees of the House of Commons). The Bill seeks power to confer further powers on the Shrewsbury Gas Light Company, with the object of meeting the demands of the district for an increased gas supply. There was no opposition, and the necessary proofs having been given, the Bill passed the Committee stage, and in due course will be reported for third reading.

THE official inauguration of the electric light supply at West Kirby and Hoylake took place on Saturday, the 8th inst. The function in itself was not an imposing one, but the lunch afforded an excellent opportunity for the members of the Council to belaud each other, and they did it with effect. The Chairman (Mr. G. Wall), after giving some figures, indulged in a sanguine forecast of what will take place now that electric light is available, which many hope may be even partially realised.

AT a recent meeting of the Electric Lighting Committee of the Beckenham District Council it was decided to recommend that the Clerk be authorised, on behalf of the Council, to sign agreements for the laying of new cables in the requisition of inhabitants, all applications for extensions of cable to be first submitted to the Committee for approval. The Committee was of opinion that it was advisable to extend arc lighting in main roads as soon as the new machinery (on order) rendered such extensions possible. The report was adopted.

THE question of dealing with the surplus of £2000 left over after paying the shareholders of the North Bierley Gas Company on the terms agreed upon between the company and the Bradford Corporation has been considered at a meeting of the directors and shareholders at which Mr. A. B. Moorhouse presided. It was moved by Mr. Wilson, of Great Horton, and seconded by Mr. Mitchell, of Little Horton, that the amount be given to the directors as an honorarium for their past services. This motion received little support, and it was then resolved to divide the money equally among all the shareholders.

THE Town Clerk of Ripon, at the request of the Corporation Gas Committee, has sent to the members of the Council a copy of the annual gas report and accounts prepared by the Deputy Town Clerk and Manager. During the year ending March 31st, 1901, the quantity of gas made at the works was 39,500,000 cubic feet, a decrease on the previous year of 500,000 feet; the gas sold being 30,921,930 feet, a decrease of 968,510 cubic feet. The quantity of coal carbonised was 4618 tons, which yielded on an average 8554 cubic feet of gas per ton; the gas sold being equal to 6696 cubic feet per ton, showing a leakage of 16·5 per cent., the same as last year. Part of the leakage was owing to the laying of new mains, the bad condition of the old holder, and condensation. No cannel coal was used. From the balance sheet it appeared that the loss after paying sinking fund and interest amounted to £1093 7s. 7d.; and exclusive of sinking fund and interest the profit was £89 7s. 3d. The sum of £1118 8s. 3d. was due to the treasurer on the gas reserve fund account. The loss on the total contracts rejected by the Council in February, 1900, amounted to £575 for coal, and £110 13s. extra cost of labour and storage, in consequence of the altered conditions of the delivery in the new contracts.

GENERAL.

THE Newbury Corporation contemplates the erection of a hospital for cases of infectious disease.

THE Stretford Urban District Council has decided to erect baths at Old Trafford, at a cost of £12,500.

AN inquiry was held at Warrington last week with reference to a proposed loan of £7000 for the extension of the public baths.

THE Stepney Borough Council has resolved to apply to the London County Council for £9000 towards the cost of widening Narrow-street, Limehouse, which work is in progress.

A LOCAL Government Board inquiry was held at Swansea last week with reference to the applications of the Corporation for sanction to the borrowing of £425 for public conveniences, £286 for street improvements, and £50 for slaughter-house purposes. After hearing the evidence the Inspector visited the sites.

AT its last meeting the Birkenhead Town Council approved the recommendations of the Tramways Committee to borrow £11,101 for providing double tracks in place of single tracks on certain sections, £13,000 for fifteen additional cars, £7500 for extra generating plant, and £1000 for repairing plant at the North End depôt.

COLONEL LUARD held an inquiry at Warmley last week with respect to an application of the Warmley Rural District Council for sanction to borrow £2000 for works of street improvement in the parishes of Mangotsfield and Oldland, and for the powers conferred upon Urban Authorities by Section 154 of the Public Health Act, 1875.

THE Camberwell Borough Council has decided, upon a report from Dr. Bousfield, its bacteriologist, to sanction the purchase of a small gas engine at a cost not exceeding £40, for use in mechanical work connected with the detection of tuberculosis in milk, especially condensed milk. Dr. Bousfield proposes to test the milk sold in the borough.

AT the last meeting of the Grimsby Sanitary Committee, a Sub-committee presented a scheme for the provision of a refuse destructor. The cost had been estimated at £10,500, and the Committee recommended that the tender of the Horsfall Company, of Leeds, for the erection of a destructor, &c., at a cost of £8507, be accepted. This was adopted.

THE Sanitary Committee of the Derby Town Council has decided to recommend the Corporation to adopt Part 3 of the Housing of the Working Classes Act, 1890. The Act enables Corporations to acquire land on which they can build lodging-houses for the working classes. Its adoption has been urged by sanitary reformers in Derby for some time past.

THE Vaccination Officer for the Poplar union informs his Board of Guardians that until the present time he has been able to avoid taking extreme measures to secure compliance with the Vaccination Acts, but that owing to the persistent activity of those who take exception to the Acts, it will be impossible for him to go further without making an example of a few of the strongest opponents of vaccination.

A SERIES of experiments with the Marconi system of wireless telegraphy are at present being undertaken between the school ship Conway and the Cunard Royal Mail steamer Lucania. The experiments are being regarded with great interest by members of the nautical profession, and the parents of the cadets on the Conway will have the satisfaction of knowing that an effort is being made to keep their sons up-to-date in nautical knowledge.

AT the last meeting of the Finsbury Borough Council the Public Health Committee reported that the Medical Officer of Health had drafted a circular directing the attention of the milk dealers of the borough to the necessity of keeping a register of the sources of their milk supply, and of obtaining guarantees from farmers that no infectious disease existed at the farms or in the homes of those engaged thereon. It was decided to ask the Local Government Board to approve of the circular.

PERSONAL.

Mr. Greig has been appointed Borough Electrical Engineer for Bury St. Edmunds.

Dr. Babet has been reappointed M.O.H. for Willington Quay for the ensuing three years.

Mr. Wilson, of Hampstead, has been appointed Assistant Inspector of Nuisances for Enfield.

Dr. Wigham has been appointed Borough Medical Officer of Health for South Molton.

Mr. D. Ellison, of Darwen, has been appointed Assistant Borough Surveyor for West Bromwich.

Mr. T. Bradshaw, of Manchester, has been appointed Inspector of Nuisances for Dorchester.

Mr. F. W. Enrich has been appointed Pathologist and Bacteriologist to the Bradford Corporation.

Mr. H. B. Miller, Town Clerk of Yarmouth, has been appointed as Town Clerk of Norwich.

Mr. R. W. Woods has been reappointed Inspector of Nuisances for the rural district of Northampton.

Dr. W. Gruggen has been unanimously reappointed Medical Officer of Health for Tring for the ensuing year.

The Local Government Board has approved the appointment of Mr. Thompson as Inspector of Nuisances for Ripley urban district.

The Droxford Rural District Council has increased the salary of its Sanitary Inspector, Mr. Robert Johnson, by £35 per annum.

Mr. J. Young, of Shanklin, has been appointed Inspector of Nuisances and Town Inspector for Shanklin, at a salary of £90 per annum.

Mr. W. N. Blair, County Surveyor, has been reappointed Borough Engineer and Surveyor of St. Pancras, at a salary of £700 per annum.

The Local Government Board has authorised the reappointment of Dr. H. C. Sharp as Medical Officer of Truro, at the usual salary, viz., £50 per annum.

Mr. J. E. Walker, of Hunstanton, has been appointed Surveyor, Sanitary Inspector, and Water Bailiff for the urban district of Ledbury, at a salary of £75 per annum.

Mr. F. A. Channing, M.P., proposes to introduce a Bill providing that no prosecution under the Vaccination Acts shall be commenced without the authority of the Guardians.

LAW CASES.

An Insanitary Dwelling-house.

An extraordinary state of affairs was disclosed in Edinburgh Police Court, when Dr. A. M. Williamson, Chief Sanitary Inspector, appeared as a witness in a case at his instance against Mrs. Diana Hargrave Wardlaw, 22, Royal-crescent, for having accumulated within her dwelling-house a quantity of filth, dirt, and offensive matter. The accused pleaded not guilty.

Dr. Williamson stated that he visited the house on the 10th of this month, and, without exception, he considered it to be the filthiest place he had ever been in. The dining-room and the room to the front were simply littered with rubbish, ashes, &c., which in some places was almost knee-deep. Every one of the cupboards was packed full of chaff and filth. It seemed to him to be the collection of years. The place was a perfect rubbish toom. In his opinion there was a great risk to all the citizens who lived in the immediate district. So bad was the place that he had been compelled to call on the accused to clean the house. The landlord sent a cart to remove the rubbish, but the accused sent the cart away.

The accused said that she was in the middle of spring cleaning, and had not managed to get the rubbish cleared away. She denied that a rubbish cart had been sent to her house. In one of the rooms, she admitted, there was a bundle of fish, which sent out such a strong odour that Dr. Williamson walked about with his handkerchief at his nose. (Laughter.)

Dr. Williamson intimated that he was anxiously awaiting the conclusion of this case in order to proceed with another prosecution.

The accused exhibited a cool indifference to the proceedings, and smiled while Dr. Williamson related his sensational story.

Bailie Telfer imposed a fine of £2, the alternative being ten days.

A Lodging-house Keeper's Conviction.

Bernard McGhie, lodging-house keeper, Paisley, was charged at the instance of the Paisley Town Council with having failed to fill up certain schedules as required by an order of the magistrates. The facts were that during the prevalence of the small-pox epidemic in Paisley last spring, about the month of February, the Public Health and Slaughter-house Committee of the Paisley Town Council issued an order that the keepers of every common lodging-house in the burgh should be required from time to time to report to the Sanitary Inspector every person who resorted to their houses on the preceding day and night, and they were to be furnished with schedules for this purpose. These the accused had neglected to fill up. He was convicted and fined £1. An appeal having been taken to the High Court of Justiciary, on the ground that the schedules were not in terms of the statute, that it was *ultra vires* of the Local Authority to demand the information and on other technical grounds, the appeal was dismissed, the Lord Justice Clark remarking that a more hopeless appeal he had never seen.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2237.—Isolation Hopsitals: Book on.—"R. H. H." writes:—"I am desirous of obtaining the latest up-to-date work on the construction and management of isolation hospitals. I have Dr. Thorne's book, Report to the Local Government Board on "Infectious Diseases Hospitals." What other books would you recommend?"

Answer.—There are very few books published on the subject of infectious hospitals. The only other book we can recommend beyond that mentioned by the querist is Burdett's "Cottage Hospitals, General Fever and Convalescent," price 10s. 6d. post free from the office of this journal.

2238.—Bakehouse: What is Drain Opening therein?—"Constant Reader" writes:—"I enclose rough sketch of bakehouse which has been reported as having two drains in it for the purpose of carrying off slop water, and a notice has been served on the owner to remove the drains. Would you please advise whether the drains are, in your opinion, within the bakehouse?"

Answer.—From the sketch submitted the drain openings are not within the bakehouse, but are each in the area outside the bakehouse. The Authority could not succeed in proceedings for the removal of the gullies in question.

2239.—Housing of the Working Classes Act: Closing Order.—"F. T. C." writes:—"This Urban Authority had a certificate from their Medical Officer of Health that a certain dwelling-house was unfit for human habitation, and a resolution was passed that proceedings should be taken for the purpose of closing same. At the same meeting the Sanitary Inspector asked for a statutory notice to be served on the owner of four houses to put the same in a habitable condition, and a resolution was passed authorising same to be served. The whole of the said five houses form one block. The statutory notice has been served on the owner with regard to the house certified by the Medical Officer of Health for the same to be put in a habitable condition. Please advise whether proceedings could be taken for the express purpose of closing the house without the above

notice being served by the Clerk? I may add that no previous notice had been served on the owner."

Answer.—The proper procedure is first to give notice to the owner or occupier to execute the work necessary to put the house in proper condition. Then, if the owner makes default, or if the nuisance is likely to recur, the Local Authority may summon the owner or occupier before the Justices, who may make a closing order. See Allan's "Housing of the Working Classes Acts" (second edition), price 7s. 6d., obtainable from the office of this journal.

2240.—HORSEFLESH SOLD AS HUMAN FOOD.—"E. T. M." writes:—"A butcher has purchased horseflesh from a knacker's yard and sold the same as beef. Could proceedings be instituted against the knacker for selling the same to the butcher? The difficulty lies in the fact that the butcher lives in an urban district and the keeper of the knacker's yard in a rural district. The butcher will be prosecuted by the urban district. I am anxious to know whether this Urban Authority can prosecute the knacker as well, either for selling meat known to be horseflesh without being labelled as such, or for selling unwholesome meat."

Answer.—In our opinion the Urban Authority will not be enabled to successfully institute proceedings against the knacker. The sale to the butcher does not appear to have been made within their district, but in the district of the rural Sanitary Authority, and the latter authority (if any) should institute proceedings against the knacker.

2241.—HOUSE DRAINAGE: MAKING JUNCTION OF HOUSE DRAIN WITH SEWER: WHOSE DUTY.—"D. L. O. G." writes:—"When owners of property require to connect their drains with the public sewer, will you kindly advise as to whose duty it is to excavate the ground around the sewer sufficient to fix a junction pipe for the drain? I may say that I am of opinion that it is the Council's duty to fix and prepare junctions for private drains, but my co-officer and some of the councillors differ, and say the ground around the sewer should be excavated by the owner, and the Council's duty ends with fixing the junction."

Answer.—The querist is wrong. It is not the duty of the Council to excavate any part of the ground around the sewer for the purpose of fixing the junction. Neither is it compulsory on the Authority to provide a new junction for each connection. It is, however, a general practice for Local Authorities to do so, so as to ensure that the sewer is not damaged by unskilful workmen. Many authorities, however, charge owners a fee to cover the cost of labour and materials for the work.

2242.—BUILDING LET ON REPAIRING LEASE: NOTICE UPON WHOM TO BE SERVED.—"E. R." writes:—"Your opinion is asked as to who, under the following circumstances, is liable to repair a defective outdoor water-closet, viz., A lets a house to B at a yearly rent, an agreement having been made that A will keep the outside of the premises in good repair and order, B undertaking to keep the inside in good condition. The agent of A declines to do anything to it, and maintains that B is liable?"

Answer.—The Sanitary Authority must follow the procedure prescribed by the Act, and serve upon A (the owner) who is the person liable. It is not the province of a Sanitary Authority or their officials to recognise private agreements. The Act prescribes that notice must be served upon the owner when structural defects are to be remedied, and the officer has no business to recognise such an agreement as that referred to. Moreover, B is not the owner, and a notice served upon him would be invalid.

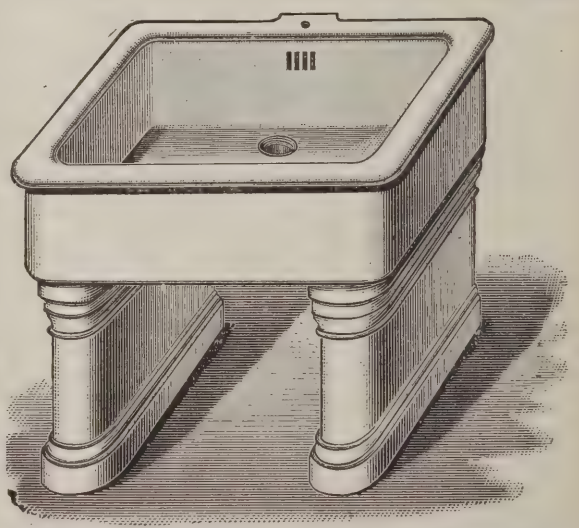
On White Glazed Fire-Clay Supports.

In appearance nearly equal to Porcelain, which they greatly excel in strength and durability. Admirably adapted for use in Kitchens, Sculleries, Butlers' Pantries, Laboratories, &c. Extensively used in houses of the better class, and in many important buildings throughout the country during the last thirty years.

Adopted by H. M. Board of Works, H.M. Commissioners of Prisons, &c.

Awarded First Prize Medal by the Sanitary Institute of Great Britain



J. & M CRAIG, Ltd., KILMARNOCK

PUBLIC LIGHTING BY GAS & ELECTRICITY

By W. J. Dibdin, F.I.C., F.C.S.,
Late Chemist and Superintending Gas Examiner to the Metropolitan Board of Works and the London County Council.

(*Continued from page* 425.)

CHAPTER XIX.—EFFICIENCY OF ARC AND INCANDESCENT LAMPS.

The intensity of various arc and incandescent lamps was formerly greatly exaggerated. For instance, in many cases three or four hundred candle-power lamps were calculated as being equal to a thousand candles. This error was soon corrected by the results of the photometrical experiments made by the writer under the direction of the Metropolitan Board of Works in connection with the Thames Embankment experiments with the Jablochkoff arc lights.

The following extracts from the report of Sir Joseph Bazalgette, the engineer, and Mr. T. W. Keates, the chemist to the Board, form an interesting and valuable contribution to the photometry of the arc lamp, as the principles there involved are still those concerned in all similar installations.

* In consequence of the dazzling nature of the electric light, and its tendency to injure the sight of persons exposed to its influence, it is necessary that the naked light should be screened. Opalescent glass globes have been used by the French society both in Paris and in London, and these have been in use on the Embankment, with the exception of one lamp, from first to last. The effect of this opalescent glass is to soften and diminish the light, so that it is possible to look fixedly at the globe without any distress, but at the same time the available light is lowered to a very great extent. A different kind of globe, having a frosted surface, has been used for some time under the Hungerford Railway Bridge; this globe stops much less of the light than the opalescent glass.

A number of experiments was made at the machine house on the Embankment, where a complete photometer was fitted up. These experiments were (1) upon the naked light, (2) upon a light with opalescent globe, (3) upon a light with a frosted globe. The measurements were made horizontally in each case.

In every experiment the electric light was placed 240in. from the measuring light, and the photometer screen moved between them, a star disc being employed in consequence of the difference in the colour of the lights, precluding the use of the ordinary greased Bunsen disc.

Twenty readings or observations were made in each experiment, both with the open and shaded lights. Eight experiments were made on as many different nights. The following are the results obtained :—

Naked light	378·1 sperm candles
Opal globe	154·9 sperm candles
Frosted globe	265·0 sperm candles

The light passed by the opal globe was, therefore, equal to 59 per cent.; by the frosted globe only 29·9 per cent. These results show the effect of enclosing the electric arc by globes, and serve as useful guides to indicate the loss of light resulting in all similar cases.

When the arc lamp was introduced on the Thames Embankment in 1879, some experiments were made at the suggestion of the writer to ascertain the effect of enclosing the carbons in closed glass vessels, with a view to reduce the rate of their oxidation. The peculiar action of the Jablochkoff "candle," however, was not favourable to the method, an undue amount of deposit appearing on the surface of the glass, with the result of largely reducing the effective power of the light. Later on, when the improved forms of the Brush and similar lamps were introduced, further trials were made by the writer in conjunction with Mr. de Segundo, with most satisfactory results, it being found that the life of the carbons could be prolonged up to as much as ten times, but at this rate the character of the arc was not so satisfactory, as a carbon button formed on the negative carbon, with a consequent dimming of the light. When a slow stream of air was allowed to enter the small encircling glass pear-shaped vessel surrounding the arc, just sufficient in quantity to oxidise the particles of finely divided carbon as they were carried from the positive to the negative carbon, the light remained perfectly steady and of the original intensity. The following are some typical results of the experiments thus made :—

Relative Consumption.

Without apparatus ... ... 1·22in.
With apparatus ... ... 0·31in.

$$\text{Saving } \frac{(1{\cdot}22 - 0{\cdot}31)\,100}{1{\cdot}22} = 74{\cdot}6 \text{ per cent.}$$

Just as these results had been arrived at by a course of laborious photometrical and electrical testings, it was ascertained that patents had been secured in England and America for precisely the same method. The system is now in use in the form of the Jandus lamp, the special features claimed for it being that one pair of carbons consuming 4 ampères will last for about 200 hours without any attention whatever; with 5 ampères for 130 to 150 hours, and with 6 ampères from 100 to 120 hours.

(*To be concluded.*)

SANITARY LAW (A).*

By Trevor Edwards, Esq., West Riding Solicitor.

THE PUBLIC HEALTH ACT, 1875, AND THE MODEL BYE-LAWS THEREUNDER.

(*Concluded from page* 538.)

Thirdly—Powers of entry upon private premises.

The following are the sections dealing with the subject:—

Section 41. To examine a drain, water-closet, earth-closet, privy ashpit, or cesspool, on complaint of any person to the Local Authority of a nuisance.

Section 85. To inspect a common lodging-house.

Section 98. To carry out an order of the Court for abatement of a nuisance when the person upon whom the order has been served has failed to observe it.

Section 102. To examine generally as to the existence of any nuisance.

Section 119. To search for unsound food on a Justice's warrant.

Section 137. To enter upon premises and vessels to execute or superintend the executing of regulations of the Local Government Board relating to epidemics.

Section 169 (by incorporating the Towns Improvement Clauses Act, 1847). To inspect slaughter-houses.

Section 305. To execute certain works necessary to carry out the purposes of the Act.

This last section is, you will find, divided into three or four distinct parts. I commend it to you for discriminating perusal.

We all find in the humdrum of daily life that the act often repeated drops in our minds to common routine and loses the halo of heroism that would attach to it if it were performed once or at long intervals. This is your danger, and you must resist it, and the thought that you are safeguarding human life and not so much removing disagreeables may assist you in this. If you fail to maintain your duty at its high level, the ideal of your work will become so commonplace that you will discharge it only perfunctorily, and you will have ceased to be the trusty custodian of your high charge.

From my knowledge during the past ten years of the development of sanitary work in the Riding, and of the work of the two eminent County Medical Officers of of Health, Dr. Whitelegge and Dr. Kaye of that period. I have no doubt that, as means are afforded to our army of sanitarians, they will lay hold of the same; and as years go by, the result of their work will be a much lower death-rate and universal house and personal cleanliness.

* Third Lecture delivered to the Health Officers of the West Riding of Yorkshire April 27th, 1901, at the Philosophical Hall, Leeds.

QUESTIONS.

Q.—Does a nuisance arising from the noise of a feast or fair come within the province of an Inspector of Nuisances?

A.—An Inspector of Nuisances is not concerned with such a nuisance in the execution of his duties under the Public Health Acts.

Q.—In a long row of houses belonging to one owner, a slop-water closet is blocked, and in consequence a serious nuisance is caused by the sewage damming over surface of yard. Who is responsible for the abatement of the nuisance—the owner or occupiers? If occupiers, which, as there are persons from two houses attending the water-closet?

A.—The occupier is liable, unless the nuisance arises from the defective construction of the water-closet, when the liability falls upon the owner (Section 94). If the nuisance arises from the acts or defaults of the occupiers of two houses, proceedings may be taken against either or both (Section 255).

Q.—Has an Assistant Inspector (in the absence of his chief and Medical Officer) power to seize unsound meat, &c.?

A.—On the wording of Section 116 of the Public Health Act, 1875, this power is restricted to "any Medical Officer of Health or Inspector of Nuisances." The power cannot apparently be exercised by an *Assistant* Inspector in the absence of the Medical Officer of Health or Inspector of Nuisances.

Q.—If an Assistant finds an unsound or diseased carcase of meat and leaves it in order to communicate with his chief or Medical Officer of Health, and the owner disposes of it in the interval, does he render himself liable to be dealt with under the provisions of Section 118 for obstruction?

A.—No.

Q.—Would the finding of a diseased carcase of meat inside a slaughter-house (not exposed for sale) subject the owner of such carcase to a legal penalty?

A.—The Towns Improvement Clauses Act, 1847, which is incorporated with the Public Health Act, 1875, empowers an Inspector to enter a slaughter-house and seize any carcase found there which appears unfit for the food of man without regard to the question whether it is intended for sale or not. If the meat is subsequently condemned and an order made for its destruction the owner is liable to a conviction.

Q.—Can an Inspector go into a private house if he knows that unsound meat is going to be used by the inmates—say workpeople? Is the occupier liable to a penalty?

A.—The powers of inspection and seizure of unsound meat given by the Public Health Act, 1875, can only be exercised (except as to slaughter-houses) in respect of meat or food intended *for sale* or for the food of man.

Q.—Would it be legal for a Justice of the Peace to give an order for the destruction of diseased meat upon

the certificate of a Medical Officer of Health, or Inspector of Nuisances, he (the Justice of the Peace) not having seen the meat?

A.—In my opinion, the Justice must see the meat before he can make any order.

Q.—Can a Local Authority require an owner of a cottage property to erect a ventilating pipe on his property, which will only ventilate the public sewer when the drains from each are connected directly to the sewer? (Public Health Act, 1875, Section 19.)

A.—No.

Q.—Some time ago a drain passing under a building was found to be choked, and when opened was found to receive the sewage from two other properties. Each of the owners contributed to the repair. The drainage of an adjoining owner is now found to require repair, and a sufficient fall cannot be got on his property. Can the Local Authority require him to connect his drains to the first-mentioned drain without the previous consent of the owners who had it repaired?

A.—As the first-mentioned drain receives the sewage of several properties, it appears to be a sewer, and is accordingly vested in the Local Authority. The adjoining owner, may therefore be required to connect his drain with the sewer, provided that it is not more than 100ft. from the site of his house, and the consent of the owners who repaired the sewer is not required. The order of the Local Authority will not, however, entitle the adjoining owner to enter upon private land to execute the work without the consent of the owner of the land.

Q.—Forty to fifty back-to-back houses, in detached blocks, extend along one side of a street. Some of the front houses are drained into the sewer in said street, but the sewage from the back houses, and many of the front ones, is discharged at the back of the houses on to the hillside, giving rise to a series of nuisances where the pipe drain from each block ends. Several owners are involved:—(*a*) Can the Local Authority require these owners to combine to make a drain for the whole of the properties and connect the same to a sewer which is more than 100ft. from the houses under Section 23; or (*b*) is it not the duty of the Local Authority to make a new sewer sufficient for effectually draining the district and connect thereto existing drains from the houses under Section 15?

A.—(*a*) No. (*b*) Having regard to the number of houses in question, I think there is a duty upon the Local Authority to make such sewers as may be necessary to receive the drainage of the houses.

Q.—In the case of several semi-detached villas, the drains of each villa are connected to a manhole in one of the gardens, and thence to a public sewer. Is this latter part a sewer repairable by the Local Authority, or a drain for which the owner is responsible?

A.—If the conduit from the manhole to the public sewer conveys the drainage of more than one pair of semi-detached houses, it is a sewer, and repairable by the Local Authority. I assume that Part III. of the Public Health Act (Amendment Act), 1890, has not been adopted. If, however, the conduit from the manhole conveys the drainage from one pair of semi-detached houses only, it is a drain, for the repair of which the owner is liable; it has been so decided in a recent case before the High Court.

Q.—Public Health Act, 1875, Section 24:—Can a Sanitary Authority compel an owner of houses to re-drain them into a new sewer which has been substituted for another previously serving the houses by reason of the latter becoming unsuited or not adapted to the general system of a district, and who should bear the expense?

A.—Section 24 provides that a Local Authority may require a house to be drained into a new sewer under such circumstances. The Local Authority are given the power to do the work at their own expense, but not to compel the owner to undertake it.

Q.—(*a*) Can an owner of property divert a sewer in street which has become vested in the Authority for his convenience without the permission of the Public Authority; and (*b*) which section in the Public Health Act, 1875, authorises the Authority to either directly sanction or decline such a diversion?

A.—(*a*) No. (*b*) Section 18 empowers a Local Authority to divert a sewer.

Q.—Is a Sanitary Authority bound by its own bye-laws?

A.—Yes, absolutely.

Q.—The Model Bye-laws having been adopted by an Urban District Council can the Council modify them by resolution? What should an Inspector do in order to protect himself if the Council do modify a bye-law—I mean if a Local Government Board Inspector complains?

A.—No, a bye-law can only be altered by a subsequent bye-law approved by the Local Government Board. The order of the Local Government Board prescribing the duties of an Inspector of Nuisances directs that he shall "observe and execute all the lawful orders and directions of the Sanitary Authority." The orders of the Local Authority which an Inspector is to carry out are limited, therefore, by that word *lawful*. A complaint by a Local Government Board Inspector should be referred at once to the Clerk of the Authority.

Q.—What is the reason for the omission in the Model Bye-laws of the Local Government Board of a clause making it impossible for a new house or houses to be erected without closet and ashpit accommodation?

A.—This is provided for by Section 35 of the Public Health Act, 1875.

CORRESPONDENCE.

(*To the Editor of* The Sanitary Record.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

NATIONAL HONOURS FOR PUBLIC HEALTH OFFICIALS.

Sir,—Your leading article on the above subject is both timely and *apropos*. At a time when honours are being freely lavished upon those who have distinguished themselves on the veldt, it is only fit and proper that attention should be drawn to the claims of fighters in another field—claims none the less honourable because the victories achieved have been bloodless. The conquests of empire carry in their wake the cry of the widow and fatherless, but the victories achieved by the noble army of Public Health workers is open to no such reproach.

It would seem that hitherto the martial spirit has blinded the eyes of our Government to any claims to distinction other than these associated with kharki. But while we honour the brave who have taken up arms for the defence of the Empire, let us not forget those who do battle with a far more insidious foe even than the Boers—those who wage incessant war against disease and rescue the rank and file of our slums from its devastating inroads. As the poet says—

"Peace hath her victories,
No less renowned than war."

I think the time has arrived when our legislators should acknowledge this much by bestowing at least a few honours on those who, if less in evidence to the naked eye than the man in kharki, are every whit as brave and deserving.—Yours faithfully,

Westminster S.W., June 23rd. M. P.

MUNICIPAL AND COUNTY ENGINEERS.

ANNUAL MEETING AT LEICESTER.

THE PRESIDENT'S ADDRESS, BY E. GEORGE MAWBEY, M. INST. C.E.

In very gratefully receiving at your hands the highest honour you can confer upon me, I fully appreciate and value this proof of the esteem and confidence of the Council and the members generally in unanimously electing me your President. I naturally feel proud of this compliment to the town and myself, and I shall earnestly endeavour to do all in my power for the advancement of knowledge and practice in the many branches of municipal engineering and the multifarious duties devolving upon us for the health, comfort, and well-being of our people, and also for the prestige and still further progress of the Association and the benefit of our members, and, in this, I know I shall have your loyal support and the assistance of all your representatives in office.

After twenty years' membership, and being installed your President at the first annual meeting of the new reign and of the twentieth century, I might have given you an exhaustive retrospect of the achievements and enormous strides in sanitary science and the important part taken in them by our profession and members during the great and glorious reign of our much-beloved late Empress-Queen Victoria (whose loss touched our hearts more deeply than can ever be expressed), but those subjects have been so ably dealt with, in admirable addresses by one or other of my eminent predecessors, that I propose to refer to them only briefly in taking up some of the most important questions of the present day affecting municipal engineers.

Vast and various as have been the enterprise, research, invention, and achievement throughout the British Empire during the Victorian era, the reign of our illustrious Sovereign, King Edward VII., bids fair to make a record of unparalleled advancement. This is, in many ways, a time of great promise, and from what has already transpired, we well know that his Majesty's most powerful efforts will be exerted in the encouragement and development of any good work or movement which will tend to promote and maintain the health and happiness of his people, as well as the peace and prosperity of our great Empire.

It is now fourteen years since our highly-esteemed *confrère* and friend—and my predecessor—the late Mr. Joseph Gordon, was installed your President in this room, and twelve years on the 9th November next since he was so suddenly taken from us at the very zenith of his power, so soon after he was elected Chief Engineer to the London County Council; and we have recently sustained another serious loss to our profession by the death of our very able and delightful *confrère*, Mr. W. Santo Crimp, in addition to others much missed, sad events which do not get erased from our memories.

In our volumes recording the successful meetings held here in 1884 and 1887, the works of Leicester are duly described, and at the autumnal meeting in 1893 I completed the record of Mr. Gordon's splendid work. Therefore, in connection with the subjects of general and universal interest upon which I wish to speak, I shall, in referring to Leicester works as practical examples, deal more particularly with what has been done here during the twelve years I have had the honour of being the Borough Engineer and Surveyor.

Few, if any, towns have shown greater enterprise and public spirit, or have made greater progress in recent years. The population, twelve years ago, in 1889, was 138,000. In 1891, when our Borough Extension Scheme was promoted and won, it was 174,624. At this 1901 census it had risen to 211,574—an increase of 29·5, 21·16 per cent. in the decade. The rateable value in 1889 was £522,309; in 1891, after the extension, £649,583; and it is now £841,301—an increase of 29·51 per cent. in the decade. In the twelve years, 41¼ miles of new streets have been made and sewered on the duplicate system, bringing the total length of streets and roads up to 178 miles, against 76 miles before the extension of the borough. Plans have been approved since 1889 for 15,535 dwelling-houses, 167 warehouses, 179 factories, 313 workshops, 314 special buildings, 10,968 miscellaneous alterations and additions, new drains, &c., and for 386 new streets, the whole covering over 500 acres of additional built area, and involving an expenditure of (very roughly speaking) about £7,000,000 sterling, which speaks with a peculiar eloquence of the progressive commercial prosperity of the town.

During this period Local Government Board inquiries have been held upon 226 subjects affecting my department, for new works and improvements, involving the expenditure of about one and a-quarter millions sterling, and I have, at the present time, for this Corporation, schemes in hand representing a cost of nearly a million sterling, for most of which the loans have not yet been obtained, and the routine expenditure by the various committees in matters affecting my office amount to about £80,000 per annum. Regarding our every-day work, I cannot speak too strongly on the great necessity — as one of the best practical means of safeguarding the health of the community — for Local Authorities being liberal in providing an adequate number of well-qualified and properly-remunerated Building and Sanitary Inspectors, working under able administration.

The good effect of the great sanitary works and efforts of this Corporation is vividly shown by the steady and maintained diminution of the death-rate. The average from all causes during the decade of 1861-71 was 25·95; 1871-81, 24·47; 1881-91, 19·38; and during the last decade to 1901 only 17·54.

With regard to the designing of the various classes of public buildings, in some towns a separate architectural department has been organised. In Leicester the ordinary architectural work is done by my staff, and the most important public buildings by our architects in private practice. Nevertheless, in connection with all these, an immense amount of preliminary work necessarily falls upon the Borough Engineer in advising and assisting various Committees, preparing preliminary plans and estimates with detailed conditions for competitors, and outlining the schemes before the work reaches the architects. This is, however, I think, a far preferable plan than to set up an architectural department outside the control of the Borough Engineer, and much more fair to the architectural profession.

Referring, in passing, to other departments, the town owns the gas, electric light and water undertakings, and parliamentary powers have been just recently obtained jointly with Derby, Nottingham, and Sheffield for carrying out the great Derwent water scheme. Since 1889, 120 miles of public and private foul and storm-water sewers have been laid in the borough. Mr. Gordon's intercepting sewerage scheme and pumping station has been carried out at a cost of about £163,000, and has proved very successful; and my storm outfall scheme, which many of you saw in progress, and which has cost about £80,000, has also been completed. It is, however, one regrets to say, not unusual for municipalities, after having provided ample intercepting sewers, to leave in use in old and densely-populated parts of the town defective and dangerous sewers of the worse type, such as used to be designed and laid before the days of our Association.

Several years ago I drew attention to the existence of many miles of such sewers in Leicester, and the probable ill-effect upon the inhabitants living in those districts. I was promptly instructed to examine and report upon

them, with the result that I condemned thirty-two miles, and am now carrying out a scheme to replace them, which I have designed, and which is estimated to cost £128,000.

This brings me to the subject of sewer ventilation, and, although we have not yet arrived at an unanimity of opinion on this question, the chief trend of practice has been in the direction of the abolition or reduction in number of surface grids and the increase of shaft ventilation. In Leicester I carried out tests during a period of between five and six years, and made over 3000 observations of the velocities obtained in the shafts, besides very numerous records of temperature, humidity, wind, velocity, barometrical pressure, and the like. These practical experiments convinced me that sewers could be efficiently ventilated by pipe shafts alone in conjunction with very ample means of flushing.

After the results of these experiments had been submitted at an inquiry here, the Local Government Board passed the first section, namely, of eight miles of the before-mentioned tributary sewerage scheme, with ventilation provided by shafts without any surface grids whatever—a new departure in the requirements of the Board. No surface grids are now provided on any new public or private sewers laid down in this town.

The purification of sewage is one of the greatest and most perplexing questions that has confronted municipal engineers. Many have experimented, and there is still much difference of opinion. The investigations of the present Royal Commission on Sewage Disposal have already been very extensive, and will doubtless prove the most exhaustive and valuable research on record. Some think that the Local Government Board might now relax their requirements and pass schemes for bacterial treatment alone. This is not surprising, having regard to the success which has been obtained by bacterial methods. I have, however, maintained that until sufficient experience has been gained to prove that the sewage of the manufacturing towns can be successfully and permanently purified without application to land, the Board are justified, in the main, in adhering to their present attitude, for land is an immense safeguard in connection with any sewage scheme. Still, in cases where it is almost impossible, except at a prohibitive cost, to obtain it, I believe that the requirements of the Board might reasonably be modified. In fact, leniency has already been shown in special cases, and we may probably expect greater facilities when the eagerly awaited report of the Royal Commission has been issued.

Some of the main questions at issue are—(A) whether the sewage of manufacturing towns and districts can be successfully treated with maintained efficiency without application to land; (B) whether it is better to adopt the fullest anaërobic preliminary treatment in covered septic tanks with final purification in contact beds, or whether only to employ a partial anaërobic treatment in open or closed tanks with a maximum aërobic purification in contact beds; (C) further, whether preliminary chemical treatment may not also be necessary in some instances where strong trade liquids obtain. The question of intermittent or continuous treatment in the contact beds is also a debateable point, but the extreme aspect is whether, even where suitable land is available, it would not, if admissible, be more desirable to adopt bacterial treatment entirely than a combination of it and land treatment. Again, what is to-day the best course to adopt where existing sewage farms, for want of sufficient area, means of preliminary clarification or other causes, yield more or less unsatisfactory effluents?

The local conditions and the character of the sewage vary so considerably in different towns and districts that it is obviously impossible to determine upon any one system which would be universally applicable. These questions can, however, be more reliably dealt with by giving you facts as to how we have successfully solved the problem for Leicester than by mere expression of opinion. Twelve years ago, when I came here, and up to 1891, the river Soar in summer time was a black stream of horribly offensive sewage matter, which, in that highly putrefactive condition, reached miles down the river, although everything was done at unlimited cost, in chemical treatment at the old works.

In consequence of the difficulty of obtaining porous land in sufficient quantity and suitable locality, my predecessor had, much against his will and advice, to fall in with the adoption of our present exceedingly dense clay farm at Beaumont Leys, which it was widely prophesied would result in failure. The first contract, amounting to £10,400, for receiving tanks, carriers, culverts, &c., for part of the farm was well in hand when I succeeded Mr. Gordon. The total cost of laying out has been £59,025, or about £43·56 per acre for the 1355 acres actually prepared for receiving sewage.

The great problem, then, before us was how to so lay out, prepare, and under-drain the land for broad irrigation as to ensure efficient purification and to prevent the foul effluent, which always reaches the drains of a clay sewage farm, from getting away to the water-courses. This we succeeded in doing by providing for each field a separate system of drainage, so designed that the foul drain effluent can be brought on to the surface of the sloping land and treated over and over again until fit to send away. This, with other arrangements, together with the services of an exemplary committee and efficient farm bailiff, resulted in our dense sewage being purified for over nine years to the satisfaction of the Leicestershire County Council.

The increase of the population and the trade has been very great, and these factors, together with the conversion of 6700 pail closets into water-closets, and the proposal to pump the sewage from the 12,000 population of the added area of Belgrave, rendered it necessary to either increase the area of the farm or to adopt some means of preliminary clarification.

I have been allowed to carry out very extensive bacteriological experiments. Altogether seventeen different processes were tried, with two chief objects in view:—(1) The preliminary clarification of the sewage before application to old pasture land and ryegrass for final purification, without fouling the crops; (2) Complete bacterial purification without application to land. For preliminary clarification the system found most successful and suited to our requirements was to pass the screened and pumped sewage through a detritus tank of comparatively large capacity, then through a coarse-grained first contact bacteria bed on the intermittent system, the effluent therefrom being finished on grass. By this process eminently satisfactory effluents were uniformly obtained, notwithstanding the heavy nature of the land, and much less than half the land was required to be used than when crude sewage was applied. The final purification on the old pasture was at once a most reliable and effective process, and entirely free from offensive smell. The process for complete bacterial treatment which gave the best results was the passing of the screened and pumped sewage through the detritus tanks as before, then through treble contact beds, and the effluents from this process were only just equal to those obtained from the detritus tank, single contact and irrigation on grass land. The detritus tank and double contact process was not quite equal to either. These results were only determined by very numerous and exhaustive observations and analyses.

I consequently advised the Corporation to purchase 1270 acres of the land now leased to them, in addition to the 100 acres of freehold they already possess, and prepared a bacterial clarification scheme to assist the land, consisting of open detritus tanks with a capacity

equal to one-sixth of the present 8,000,000 gallons dry-weather flow to be dealt with, and 12 acres of first contact bacteria beds, which, together with the effluent pumping plant, new sewerage, and pumping station for the added area of Belgrave, is estimated to cost £168,000. This scheme has been unanimously adopted, and application has been made to the Local Government Board for sanction to borrow this amount.

Great inconvenience has been experienced throughout the country for want of a general Act of Parliament giving Local Authorities greater facilities for improving small rivers, brooks, and ordinary watercourses in their districts, particularly where improvement works necessary for the prevention of flooding of lands and dwellings are too small to justify the obtaining of a local Act of Parliament and too great to be defrayed out of the revenue account.

The flood which occurred at Leicester on the last day of the nineteenth century was the greatest here within living memory. Our great floods prevention works, which were mostly designed and carried out by Mr. Gordon and Mr. Griffith, and brought to a completion by myself at a cost of about £352,000, were constructed to carry off a volume equal to the whole of a rainfall of 1¾in. in twenty-four hours from the 147 square miles of drainage area, and the volume of the flow which was actually discharged and also successfully carried off during that flood was equal to a rate of rainfall of nearly 1¼in. in 24 hours. This is valuable and useful data in connection with the preparing of floods-prevention works.

I have recently designed and constructed in stone and concrete another bridge, besides those dealt with at your last meeting here, forming a new road from the Newarke over the flood course, at a cost of £15,500, which you will inspect, and I have prepared drawings and a description of it for our volume of "Proceedings." I am now designing a bridge to replace an old one of inadequate span at Belgrave, which will probably cost something approaching £25,000. I am quite unable to give you details of our different works in this address, but shall be pleased to supply later on any particulars which may be desired by you.

The rapid growth of large towns demands, for the sake of the health and vigour of all classes of workers with muscle or brain, for the children, and for those to whom we are so indebted for home comforts, that ample open spaces and conveniently-located parks and recreation grounds be provided. In Leicester we have now 410 acres of parks, recreation grounds, and children's playgrounds, altogether twelve in number, including our beautiful Abbey Park, which was opened in May, 1882, by our present King and his beloved Consort, and it has proved a great boon to the people.

Including the above, and the 1270 acres of land of the Beaumont Leys sewage farm now being purchased by arbitration, and the different estates, the Corporation will own altogether no less than 2442 acres of land and properties for various purposes, exclusive of gas and water, and so convinced are they of the advantages which would accrue, both in health and financially, with more power to acquire surrounding land, which is ever increasing in value, that they are far from satisfied with the facilities the present legislation affords.

The provision of public baths and open-air bathing stations is essentially an important health question, and there is now a tendency to combine water sports to a great extent with swimming, and to utilise the main buildings for gymnasia in the winter, with the maximum possible accommodation for spectators. Our Cossington-street baths are on this principle. We have now three public baths and two open-air bathing stations, and we are about to build another set, involving altogether an expenditure of about £50,000, exclusive of land. The last-mentioned baths are to be erected at the West Humberstone refuse destructor, from which the heat will be supplied. The swimming baths will be on the amphitheatre principle, with dressing-boxes under the seating, and, in lieu of the ordinary slipper baths, twenty-four combined washing and hot-vapour baths will be provided.

In electric traction for our streets and roads there is now opened out an immense field and future for municipal engineers. In conjunction with electrical engineers they have already played a very prominent part in the designing and carrying out of schemes in our large towns. There have been much greater enterprise and progress abroad than in this country, both in manufacture and construction, and from which we have derived much advantage; but all this is being rapidly changed, and to-day we possess, in some of our cities and towns, overhead-trolley systems, power stations, depôts, and various accessories of the very best types, with approximately about a thousand miles of electrically-equipped tramway track now in operation, mostly put down within the last decade, and several hundred miles are under construction. But perhaps nearly twenty times as much as this have been electrically-equipped in the United States, and a vast aggregate mileage throughout the Continent.

It was high time we moved. Foreign companies and capitalists are not only reaping the benefit of our traction trade, but are exploiting this country for the purpose of financing and carrying out tramway undertakings, which our countrymen, who in the past have been great pioneers in railways and other engineering works, ought, for the honour and prosperity of the kingdom, to rouse up and do for themselves, while at the same time encouraging and fostering such interchange of trade with other countries as is mutually advantageous.

Leicester, although usually in the front, is at present behind in electric traction, chiefly because the tramways are still in the hands of a company, but we intend to come into line, at least very soon. Although the overhead system has been chosen by every provincial town in the United Kingdom which has hitherto carried out a scheme, the objections to it have been so deeply rooted that a most exhaustive investigation has been made by us in the hope of finding something better, but we found nothing except the overhead trolley, which sufficiently combined reliability, safety, economy, and efficiency for a town like Leicester. We therefore recommended it, and also a separate and independent central power station.

Our preliminary scheme, which I had the honour of preparing for our Sub-committee, has been—by the full Committee—unanimously recommended to the Council, who have adopted it, subject to the site of the power station being in abeyance for the present, and I have been instructed to prepare the parliamentary and working plans, &c., for the scheme, with Mr. E. Manville as the consulting engineer. No detailed estimate has yet been prepared, but the present scheme embraces twenty-two miles of route and about thirty-eight miles of track, and, as to cost, half a million sterling is a guess which goes unchallenged, without including the purchase amount of the present undertaking.

I feel convinced that in provincial towns much more will be done to solve the question of the housing of the working classes by electric tramways than by the erection of blocks of workmen's dwellings in thickly-populated centres. Small separate dwellings, on the extreme outlying parts of a town, conduce greatly to the improved physique and respectability of the people, especially when allotment grounds are available within easy reach. We found that the experience in Brussels had been that it was not necessary to wait for the growth of a suburb before making a tramway, but that when a tramway is put down it makes a suburb, and that as unhealthy houses had been demolished in the centre of the city, the working classes gladly availed

themselves of the cheap and rapid tramway transit, and went out to the healthy dwellings which were soon provided, at reasonable rates, by private enterprise.

There is undoubtedly a great future for the autocar for light work and swift and convenient transit, and as greater perfection with regard to fuel, engines, gearing, and reduction of noise is attained, it will gradually effect a great sanitary improvement, and will considerably diminish the wear and tear of our roads and streets in comparison with horse traffic. Smart men will be their own drivers and mechanics, they can live long distances from their business, and can have their railway station in their own back yard.

Notwithstanding its great promise, the motor car is not likely, however, to supersede electric traction for public service, although very useful for feeders and auxiliary traffic. In the principal thoroughfares of large cities with electric tramcars, a one-minute service running each way is no unusual thing. This means something like 7000 persons passing a given point to and fro every hour, in an undeviating course, swiftly, smoothly, and almost noiselessly and without any confusion whatever, and even three or four times that number is quite practicable without inconvenience.

I wish here to take this, my earliest opportunity, of publicly thanking the members of the Automobile Club of Great Britain and Ireland, and of its Nottingham and Midland branches, for their great kindness in undertaking to bring their cars from different parts of the country to convey our members on their various visits in Leicester and the surrounding districts on Saturday. This excellent and unique event was kindly suggested to me by our *confrère*, Mr. E. P. Hooley, in conjunction with Mr. A. R. Atkey, honorary secretary of the Nottingham Club. The utility and advantages of motor cars will be practically demonstrated, and a great treat is expected. I therefore request your very hearty co-operation on that occasion.

I must not omit to draw your attention to the advance which has been made in steam road locomotion of late. For years past road locomotive engineers have devoted their energies to placing steam on common roads on a commercial basis. We well know that with heavy steam road locomotives the hauling of loads of from fifteen to thirty tons can be done at an extremely low cost per ton mile; but the new Locomotives on Highways Act, 1896, has produced a smaller and handier means of doing the work of several horses at an inclusive cost of less than 4d. per ton per mile. With regard to municipal work, several of the London and other Corporations are already using steam wagons for carting materials, watering streets, dust and refuse collecting, &c., and it is claimed to effect a considerable saving in cost.

What the future development of the steam wagon will be it is difficult to foretell, but the tendency will be towards simplicity of construction, higher quality of materials used, higher power of engines, increased pressure of steam, and greater economy. Nor are these light locomotives likely to increase the cost of upkeep of the roads themselves, for it must be borne in mind that with horse haulage, besides the pressure of the wheels bearing the load on the road, the deteriorating action of the hoofs of the horses must be taken into consideration. The present use of horseflesh for transporting more or less heavy loads, especially on steep gradients, is, in these days, hardly worthy of science.

One of the latest matters which we have to advise upon is the provision of short rifle ranges, similar to those at Wormwood Scrubs, which, it is urged, can be placed with safety within easy reach of every town or thickly populated district, and thereby give facilities for all our men to learn to shoot.

If such a voluntary training movement would, as some think, tend to so strengthen our nation as a fighting power, in case of need, as to substantially diminish the necessity for a very much larger permanent army, or to prevent the sacrifice of our sweet liberty by conscription, then every legitimate means towards this end might well be adopted by our Local Authorities. Our colleague, Mr. J. W. Bradley, having taken much interest in this subject, has kindly undertaken to read us a paper upon it.

The position of a municipal engineer is one of infinite variety of work and responsibility in so many branches of routine and professional duty, with a consequent strain far exceeding that brought upon his more fortunate and better paid confrère in private practice. Again, besides the unlimited theoretical and technical skill required, a successful municipal engineer must possess that peculiar power which enables him to organise and direct human effort to the best advantage, and to lead and control large numbers of men—qualities which are of superior value in every sphere of life—and it is to be hoped that Local Authorities will remunerate their own permanent engineers and surveyors to an extent fairly commensurate with their services, and thereby relieve them of the anxiety of the financial burdens brought upon them by their never ending professional education, the upholding of the respectability and integrity of their positions, and the meeting of the many claims for all sorts of objects, learned societies, &c., which their office demands, for I venture to say that many an able, exemplary, and frugal official is by no means free from such anxieties, simply because he is not adequately remunerated, although he does much extra work which would otherwise cost the ratepayers vastly more than would a reasonable increase of salary.

Security of tenure of office is a subject which has seriously exercised the minds of many, chiefly owing to unfortunate circumstances which, in several instances, have ended unfairly to the officers. It is, however, a delicate and difficult question, and, whilst some protection is needed, any attempt to restrict unreasonably the power of the Local Authorities would not tend to promote either the comfort or advancement of the officials. Superannuation for the officers of municipalities and Local Authorities generally is a question which I venture to respectfully say has by no means yet received at the hands of those Authorities the consideration it fairly deserves, although it must also be said that among the duly elected representatives of the ratepayers throughout the country it has many ardent advocates. Some towns, including Leicester, have obtained Parliamentary powers for local superannuation schemes, and some, including Liverpool, have adopted and worked them.

What is needed is a general Act, extending to all officers of Local Authorities the provisions of the Poor Law Officers' Superannuation Act. The present Local Authorities' Officers Superannuation Bill has been supported by several municipalities, but the Government will not adopt such a measure until the majority of Local Authorities have petitioned in favour of superannuation. This seems hopeless at present. The difficulty might possibly be partly met for a time by a measure giving each respective Authority the option of adopting the Act whenever they might become sufficiently convinced of the wisdom of such a step. The arguments in support of the justice of the case cannot be adequately dealt with in this address. I cannot leave this question without urging our members to support, as far as able, our admirable and much-needed orphan fund movement.

It would be almost impossible to overrate the extent to which our Association has improved the status of municipal engineers—largely by the great facilities afforded for the interchange of opinions and the obtaining of knowledge and information so willingly imparted by our members to each other in every sphere of their

work. Neither can one over-estimate the advantages accruing to Local Authorities from the experience gained by their officers attending our meetings and inspecting the numerous and varied works of our *confrères*, especially when one considers that a very large proportion of the sanitary works of the country have of late years been done by the stipendiary officials of municipalities.

Our Association, particularly by its examinations, has been the means of bringing forward many well-educated and clever young engineers into our ranks. I believe that the time is fast approaching when no young engineer will be considered duly qualified for a chief appointment who has not passed this or an equally comprehensive engineering examination. The profession and work of municipal and county engineers are of hardly less value and importance to the country than those of members of other leading professions, and our Association, with its roll of nearly 1000 members and graduates, representing practically the whole of the cities, towns, and districts of the United Kingdom and our Colonies, may be fairly entitled to equal recognition with all other prominent institutions. I think we might with advantage allow our list of eminent honorary members to be extended to admit more of the distinguished engineers and scientists of our country and of the continental cities and America, so as to facilitate to an even greater extent comparisons of practice and the promotion of knowledge in all branches of municipal work.

CLEANSING WORK IN ABERDEEN.

The annual inspection by the Town Council of the horses and carting plant belonging to the cleansing department of the city of Aberdeen took place last week. Councillor Glass, convener of the Cleansing Committee, dealing with the work of the department, read a statement prepared by the superintendent on the subject. A number of interesting statistics were presented in the statement. During the year 76,666 tons of refuse were collected from houses, shops, and streets. No fewer than 14,944,020 gallons of water had been distributed over the streets by the water carts, and 984,504 gallons were used to wash the streets. In view of the outbreak of small-pox in the country it was considered essential to adopt a more thorough system of street washing than was previously in vogue. The rotary brushes had swept 8610 miles of streets (apart from snowstorm work). The snowfall during the year was 37in., and the snow-rakes covered 5196 and the rotary brushes swept 2762 miles of streets, while 31,668 tons of snow were carted off the streets. The men on an average were on duty from 15 to 16 hours per day during the snowstorms, and £312 8s. was paid for hired horses, and £397 18s. 10d. for hired men. The income for hired work amounted to £4776. The stud numbered 87 horses, as against 83 at the same date last year. Sixteen horses were added to the stud during the year, and these were purchased at a cost of £923. The total value of the stud was £4250, being an average per horse of £48 17s. The cost of feeding and bedding was 11s. 7½d., as against 10s. 9d. for the preceding year, the difference being principally due to the increase in the price. The valuation of the stud and plant amounted to £9459 10s. 8d. Taking the years from 1893 to 1897 the total working amounted to £23,070 13s. 8d., and for the four following years to £23,350 10s. 1d., although during the latter period the work had been very considerably increased.

The Westminster City Council has decided to remodel the laundry at the Marshall-street Baths. The estimated cost is £4600.

THE VALUE OF ANALYSIS.

So many of our readers have to do with matters in which the analyst has to deal, that we think the following somewhat lengthy extract from an article in the *Engineer* on "Analysis by Experts" will be of interest. The exact position of the analyst has often been discussed, as also has been the exact value of his work. In the article quoted, an attempt is made to define these, with what success our readers must judge:—

There are numerous cases arising in daily commerce where the aid of the analyst is sought not so much for the actual figures which he can furnish but for the deduction which may be drawn from them, the object of attainment in the majority of cases which we have in mind being the imitation of the goods of a trade rival. Now there are many instances which could be cited where the more painstaking and accurate the analyst has been in his work, the greater has been the liability to false deductions on the part of him to whom the analysis was intended to serve as guide and mentor, and this has arisen from the statement of results emphasising the existence of bodies which are but accidentally present, *i.e.*, as impurities, in the bulk of the principal components.

Perhaps it will serve to make our contention clearer if we pass from the region of the abstract and take a concrete example, and one, moreover, of an admittedly complex type. A manufacturer of rubber packings for steam purposes, let us suppose, is anxious to know why it is that the material made by an opponent has a better name amongst steam users than his own make has, and he resolves to have an analysis made in order to see where the difference comes in, so as to enable him to effect the desired alteration. More likely than not, if our packing manufacturer is in but a comparatively small way of business, he has not the services of a works chemist at command, and he therefore proceeds to submit the sample to be tested to Professor So-and-So, whose knowledge of the technology of the subject is probably infinitesimal rather than plenary. In due course a report is obtained setting out to the third place of decimals the proportions of such substances present as have not been overlooked. Now, omitting any reference to the sins of omission, however important their bearing may be, it is often found that such reports emphasise quite unimportant matters, and on account of this have a tendency to mislead rather than to guide. Let us suppose, for instance, that a large proportion of that great friend to the rubber manufacturer—we refer to carbonate of lime, or whiting, as it is commonly termed—is present. This body is never chemically pure, but always contains small and varying proportions of oxide of iron, alumina, and carbonate of magnesia. Now, the analyst in his report is almost compelled, on the score of accuracy, to estimate and record these bodies, though our present contention is that it would conduce more to the ultimate advantage of his client if he ignored their separate existence and entered them under the head of whiting. The magnesia in whiting may amount to three or more per cent.; but it would be following a false trail if the manufacturer proceeded to use magnesia to the amount stated in the analysis if he remained in ignorance of the fact that by continuing to employ the whiting he would now have nearly double the proportion present in the sample originally analysed. We hope we make our meaning clear with regard to this statement of results; what is wanted in such cases as these is not so much accurate scientific analysis, but rather figures expressive of the nature and amount of the materials present with regard to the usual state of purity in which they are employed in the particular trade concerned. It may be said that in

going thus far the analyst is going beyond his legitimate functions, and taking upon his own shoulders the burden which his client should carry himself; and certainly if manufacturers generally had a real scientific acquaintance with the composition and properties of all the materials they used there would be no need for the analyst to go beyond the limitation just referred to. But instead of this desirable acquaintance with detail being at all common, the reverse is the case, and the analyst, to be of any real assistance in the case of manufactures, must combine with his scientific knowledge that which has been derived from an intimate acquaintance with the manufacture concerned; that is to say, he must be an expert. In the light of the fact that almost every branch of manufacture now-a-days has some chemist connected with it who has made a name for himself as a referee in cases of dispute, it would seem to be preaching to the converted to insist that manufacturers should in their own interest show discrimination in selecting the analyst who is to assist them. But the recognition of the expert is not general, and it is quite the common thing to find the professor at a college or the county analyst busy with the aid of books investigating a substance of which they have possibly never heard before. Now, if we may say so, this is not as it should be—a remark which could be strengthened did space permit of our enlarging upon the details in cases of fallacious analyses. Few, we imagine, will be found to gainsay the opinion that the whole range of chemical analysis in its relation to manufactured products is much too great a study for any one man, be his attainments of the highest order, to achieve with success; and it would seem that, as is now the rule in many professions, specialisation must become more and more the goal to which the aspirant for analytical honours should direct his efforts. There is already, we are glad to observe, an increasing tendency amongst chemists of repute in some particular line to refuse work connected with matters on which they have no more than text-book knowledge, and to advise that it be sent to some one more familiar with the subject. This seems very right and proper, and where some sort of brotherhood is established among members of the craft, with the object of assisting each other on special subjects, there will be less time lost, and an undoubted gain will accrue to clients. It would be Utopian to imagine that the analyst who is prepared to analyse and report on anything which offers will ever become extinct, but his capacity for evil can be reduced to a minimum in proportion to the perspicacity shown by manufacturers in the selection of their consultants.

The case just referred to was one in which analysts of general attainments only had been engaged, to the exclusion of the expert who, in the exercise of his intimate knowledge, would have certainly reported in such a way that the indictment hurled by the manufacturer at analytical chemistry would never have been uttered. The point seems to be one of more than casual interest, in view of the continual encroachment of foreign imports on trades which have hitherto complacently ignored the possibility of such competition making itself seriously felt. The concentration of mind which the German chemist, no less than his brother in other departments of learning, has shown in various branches of applied chemistry has been taken advantage of to the full by the manufacturers of the Fatherland, to their undoubted advantage. At home we hear on all sides wailings as to our lack of technical education, and the effect which this deficiency is supposed to be producing upon our trades; but is it not possible that the means of salvation are already at hand, and that recourse to them would prove of more immediate value to particular trades than subscribing large sums of money to institutions purveying in many cases education which is anything but really technical?

THE APPOINTMENT OF FACTORY INSPECTORS.

The prospect of the passing of an amended Factory Act has aroused considerable interest in the duties, &c., of factory inspectors. Several inquiries have been made on the subject, and we cannot do better than reprint an answer given in our "Notes and Queries" column in 1898, more especially as the issue is out of print.

The appointments are of two classes:—(1) Male Inspectors of Factories, and (2) Assistants to Inspectors of Factories. The limits of age for the former class are 21 and 30, with an extension up to 38 (*a*) in the case of a person who has been occupied as master, manager, foreman, or workman in a factory or workshop, for at least seven years, and has acquired practical acquaintance with the working of factories and workshop, and (*b*) in the case of a person who may have served as a Factory Inspectors' Assistant with the certificate of the Civil Service Commissioners from a time when he was under 30. The limits of age for Assistants to Inspectors are 21 and 40. The Civil Service Commissioners state that they are authorised by the Secretary of State to make the following announcement:—"Applications for the post of Inspector of Factories or of Assistants to Inspectors of Factories addressed to the Home Secretary will be considered from time to time as occasion may arise or fresh nominations be made. In the event of more than one candidate being nominated for a single vacancy and the examination thus being made competitive, the candidates will be so informed at the time they are nominated." The salary of an Assistant to Inspectors of Factories commences at £100 a year, and rises by annual increments of £5 to £150. The salary of an Inspector of Factories is not stated, but will be found in Whitaker's Almanac for 1898, page 157, and ranges from £200 to £500. The examination fee for assistants is 10s., and for Inspectors, £3. The subjects of examination are as follows:—For Assistants (1) Spelling and handwriting as tested by dictation; (2) arithmetic, first four rules, simple and compound; (3) an elementary knowledge of the principal provisions of the law relating to workshops.

For Inspectors of Factories the subjects are:—(1) Handwriting; (2) spelling; (3) arithmetic, including vulgar and decimal fractions; (4) English composition; (5) theoretical and practical acquaintance with factories and workshops, including a knowledge of their sanitary requirements; (6) applied mechanics, including elementary mechanical drawing; (7) (*a*) the Factory and Workshop Acts administered by H.M. Inspectors of Factories; (*b*) an acquaintance with the history of factory legislation in the United Kingdom.

No person can be appointed Inspector of Factories until the Civil Service Commissioners have issued in his favour a certificate of qualification for the post. Such certificate cannot be issued until the candidate has passed to the satisfaction of the Commissioners in all the subjects specified above. When two or more candidates are nominated to compete for one vacancy the competition will be in the subjects 5, 6, and 7.

If our correspondent desires to obtain a post as Inspector or Assistant he should make written application to the Home Secretary. We must observe that examinations for these appointments do not take place at fixed intervals, but are held from time to time as candidates are nominated by the Home Secretary to fill the vacancies which occur. The application should be written on foolscap paper, and made to the Secretary of State for Home Affairs, Whitehall, S.W. It is often found to be advantageous if a candidate can obtain the aid of a member of Parliament to recommend him to the notice of the Home Secretary.

NEW PUBLIC BATHS FOR BLOOMSBURY.

In his capacity as the first Mayor of the borough of Holborn, the Duke of Bedford last week laid the foundation stone of the new swimming baths which are about to be erected in the district.

The new baths, which will occupy a prominent site in Broad-street, Bloomsbury, are an extension of the public baths and wash-houses erected in Endell-street by the Commissioners for Public Baths and Wash-houses for the parishes of St. Giles-in-the-Fields and St. George, Bloomsbury, in the year 1852. On the coming into force of the Baths and Wash-houses Act, 1846, the Joint Vestry of St. Giles-in-the-Fields and St. George, Bloomsbury, took an early opportunity of adopting the Act, and the existing baths were erected upon freehold land acquired from the Right Honourable the Earl of Harewood, the total cost of land and buildings being about £20,000. The extension which is now in hand has been commenced with the approval of the Local Government Board in consequence of the Commissioners of Public Baths and Wash-houses having arrived at the conclusion that there was a necessity for further accommodation for swimmers.

The design of Messrs. John and S. Flint Clarkson, of Ormond Chambers, Great Ormond-street, having been accepted from several others submitted, a contract with Messrs. F. Gough and Co., of Hendon, for the erection of the baths was entered into. The extension, which will have a frontage in Broad-street of 55ft. and a depth from north to south of 130ft., will provide a swimming bath 90ft. in length, with closed dressing-boxes entered from the platforms. The bath will be paved with mosaic, the walls faced with glazed bricks, and domed ceilings of fibrous plaster will be formed above the lantern lights; a gallery will run round all four sides of the bath-hall. There will also be subways all round. The bath-hall will be entered through a vestibule, &c., from Broad-street.

The height of the bath-hall will be about 40ft. from the bottom of the bath to the domes. The elevation towards Broad-street will be four storeys in height, of Portland stone, red Bracknell bricks being used for the upper floors. The elevation will resemble the existing front in Endell-street, the resemblance being intentionally made so strong that it will be clear that the two frontages are parts of one building. There will also be provided rooms for clubs, and a general supplementing of the existing accommodation. All the floors will be constructed of fire-resisting material. The water in the swimming bath will be heated by steam. Arrangements will also be made for the steam-heating of the atmosphere, so as to counteract condensation, and to enable the bath to be kept in use in chilly weather. The building will be lighted by electricity. It is anticipated that the total cost of the land and baths will amount to the sum of £25,000.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

The half-yearly general meeting of the members was held on Wednesday evening, June 12th, at the newly-acquired premises, 19, Bloomsbury-square. The report of the Executive and the balance sheet prepared by the auditor, Mr. R. J. Ward, C.A., were considered and adopted. The following gentlemen were elected to represent the Institute as delegates at the forthcoming Congress of the Royal Institute of Public Health, to be held at Eastbourne, July 25th to 30th, viz.:—Messrs. H. M. Apps, C. E. Butcher, E. Durant Cecil, H. M. Dove, J. Farley, A. R. Hutson, J. Jenkins, and E. R. Palmer.

SANITARY INSTITUTE.

DUBLIN EXAMINATION RESULTS.

At an examination in Practical Sanitary Science, held at Dublin on June 7th and 8th, 1901, the following two candidates presented themselves, and were granted certificates:—Thomas Byrne, George Ward.

At an examination for Inspectors of Nuisances, held at Dublin on June 7th and 8th, 1901, nine candidates presented themselves. The following three candidates were certified, as regards their sanitary knowledge, competent to discharge the duties of Inspectors of Nuisances under the Public Health Act, 1875:—John Mark, James Cook, Patrick Hansahan.

National Health Society.

OFFICIAL TRANSACTIONS.

On Tuesday, May 7th, Dr. Newsholme addressed a meeting of the Association of National Health Workers on "The Methods of Preventing the Spread of Disease in Connection with School Life." He first considered the extent to which infectious disease is spread by schools, showing that, although at the present time it is fashionable to attribute all infectious disease to schools, yet that since the passing of the Elementary Education Act of 1870, which provided for compulsory school attendance, and since when there has been a largely increased average attendance, there has been a decrease instead of an increase in the mortality from diphtheria, scarlet fever, and whooping-cough. There has, however, since 1870 been an increase in the occurrence of measles; measles is spread by schools, diphtheria may be, there is possibility of the evolution of ordinary sore throat into diphtheria under circumstances of overcrowding such as obtains generally in elementary schools. It is often difficult to distinguish diphtheria from ordinary sore throat at the beginning, but every child with sore throat should be excluded from school. Whooping-cough is also difficult to diagnose at first—it seems like a bad cold on the chest for the first or second week, after which the characteristic cough appears. However, even during this early period the cough is infectious, and so whooping-cough is easily spread in schools—every child with a cough which makes him sick should be excluded from school. It is a mistake to suppose that scarlet fever is more infectious during the period of desquamation—it is infectious as soon as the sore throat appears.

Attendance at school of apparently healthy children from infected households should be strictly forbidden, otherwise children may be going to school suffering from the disease in an unrecognised condition, or may be convalescent from it, or they may carry infection in their clothes. Teachers naturally urge that there is great loss of school attendance by excluding all the children from a house where there is infectious disease, but there must be greater loss if they are allowed to attend. One partial exception may be made in the case of whooping-cough; this disease chiefly spreads among children under five, therefore Dr. Newsholme thought it sufficient to exclude children from infant schools.

School attendance is much less interfered with when the infectious case is sent to hospital instead of being nursed at home. In the first case the other children of the household need only be kept away from school during the period of incubation—in the latter case they must remain at home during the whole course of the infectious disease in addition to the period of incubation.

Closure of schools is not always justifiable when

infectious disease breaks out in them, for in crowded neighbourhoods children come almost in as close contact in the streets as if they were attending school. Closure is desirable, (*a*) when there are insanitary conditions in the school itself, (*b*) when attendance at schools is greatly reduced by the epidemic, (*c*) in sparsely populated districts where children meet possibly only in school.

ANNUAL REPORTS.

Innerleithen.—The report of Dr. Brock, Medical Officer of the burgh, has just been issued, and is very satisfactory. The sanitary condition of the burgh, it is stated, is in most respects very satisfactory, the public conveniences being kept clean, and refuse being removed before 11 a.m. to a convenient place outside the town. Reeves' patent water filter is now working satisfactorily, and, with an improvement made at the fountain-head, the water is plentiful and good. The Town Council have during the year caused the owners of houses to repair their drains, and the work begun last year is almost completed. There are five bakehouses, the only satisfactory one, as has been frequently pointed out, being that belonging to the Co-operative Society. In one block of buildings, a little way out of the burgh, are three slaughtering-booths fitted up in the most modern way, and these have always been favourably reported upon. Only nine cases of infectious disease were notified during the year, viz., seven scarlet fever, one diphtheria, and one typhoid fever. The birth-rate has been very low, only 17 per 1000. The ratio of deaths under one year of age to the total births during the year was as 66 is to 1000. The deaths from all causes at all ages were 37, thus making the death-rate 14·2 per 1000 persons living.

Kinning Park.—Dr. Hugh Kelly, Medical Officer of Health for Kinning Park, has issued his annual report. He states that the sanitary condition of the burgh was very satisfactory last year. Many improvements were carried out in streets, tenements, and courts. The area of the burgh is 109·10 acres, and the average density of the population is 137·381 per acre. The births registered during the year numbered 560, showing a rate of 40 per 1000. The deaths within the burgh numbered 277, equal to a rate of 19·7 per 1000, as compared with 256 and 18·2 respectively for the preceding year. Adding the deaths which occurred in public institutions, the total mortality was at the rate of 22·71 per 1000 of population. The deaths attributed to zymotic diseases numbered 63. There were two cases of small-pox, the first that had occurred within the burgh for over five years.

Poole.—The annual report of the Medical Officer of Health for Poole (Dr. H. A. Lawton, M.D., D.P.H.) is of a very detailed character. With regard to population the report states:—"Assuming that the rate of increase in the decade 1881-1891 still continues, I estimate the population of the district to be 18,900 to the middle of the year, and 19,186 to the end of the year. The Borough Surveyor, calculating on the number of inhabited houses, estimates the population to be 19,660." As to vital statistics, Dr. Lawton says the number of births registered during the year was 261 males and 265 females, making a total of 526, with a birth-rate of 27·69 per 1000 living. This is an increase of 17 as compared with 1899. The number of deaths registered during the year was 132 males and 160 females, making a total of 292, with a death-rate of 15·37 per 1000. This is a decrease of 33, as compared with 1899. The infantile death-rate was 131·17 per 1000 births, and the zymotic death-rate 0·63 per 1000 living. The birth-rate was a little below the rate for England and Wales in 1900. The death-rate was below the average given for England and Wales during 1900, and this speaks well for the general health of the town.

Rawmarsh.—Dr. Picken, the Medical Officer of Health of the parish of Rawmarsh, has issued his report for the year 1900. The death and birth-rates are stated to be nearly identical with those of 1899, being respectively 17·36 and 40·67 per 1000 per annum. Fifty new houses had been occupied during the twelve months, the total number at the end of December being 2937. Population (estimated) 15,223 against 11,983 at the census in 1891. The mortality of infants under one year is the highest he has had to record—127 against 96; or 8·48 per 1000 inhabitants, and equal to 208 per 1000 births registered. The zymotic death-rate was 3·53 per 1000, against 4·16 for the previous year, and 2·00 for the whole of England and Wales. Reference is made to the water supply, chiefly obtained from Rotherham, and reports of analyses are appended. As to a sample of the Council's water obtained at the Great Central Station House, Rotherham-road, the Analyst states that the results shown are not wholly satisfactory. The presence of nitrates suggests contamination to a limited extent with drainage or similar impurity, possibly the drainage from cultivated land. The polluting matter had undergone tolerably complete destruction by oxidation, so that the water in its present condition was free from other than normal traces of readily-changeable organic matter.

Ramsbottom.—Mr. John Haworth, Sanitary Inspector, in his annual report to the chairman and members of the Ramsbottom District Council of the sanitary work which has been done during the past year, referring to street cleaning, says that during the past year the streets had been regularly swept, the work being done by hand in the early portions of the week, and by machine in the latter portion. The street gullies were also cleaned out weekly, but it was often found that in removing the sludge from the trap, the trap becomes unsealed and acted as a surface ventilator to the sewer, until there was a shower of rain. The practice of adding a disinfectant was of very little use, and should be dispensed with and the water cart sent round. In the main streets the danger was somewhat avoided, as during the summer months these streets were kept well watered, the water being supplied from the Corporation's mains at the fixed hydrants which are situated in the various parts of the district. During the winter time, however, the streets were far from satisfactory, especially after a snow storm, in having to wait whilst a thaw set in to clear it away. It would be much better to have the same removed from public footpaths and the streets where there was much traffic, also the streets with steep gradients, as to those people having to wade through who are not well shod, it is a positive danger to their health. On the question of drainage and sewerage the Inspector says that examinations of the drains have been made in a very large number of cases, and the smoke test applied, which had resulted in the re-laying of several of them, although through the want of proper regulations demanding this work, many were covered up without the Inspector having examined same. Trouble had arisen on several occasions and expense incurred in having to investigate the course and depth of sewers in streets through not having any record of same, and he strongly recommended this drainage and sewerage work to the Council's most careful consideration.

NOTICES.

Annual Subscriptions.—The Annual Subscription to "The Sanitary Record," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

Subscribers Residing in Scotland and Ireland are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

All applications for advertising spaces from firms in the United States should be addressed to The Trade Paper Advertising Agency, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

All Communications should be addressed to the Editor, at 5, Fetter Lane, London, E.C., and Cheques and Postal Orders should be made payable to The Sanitary Publishing Company, Limited.

JUNE 27, 1901.

CLOTHING AND DISEASE.

We are glad to observe that the correspondence which has recently appeared in our columns, commenting upon the risks of infection attached to the manufacture of clothing under insanitary conditions, has found its way into the representative organs of the tailoring Press. It is also notable that, so far from pooh-poohing the idea or characterising it as a "fad," the more important of these journals practically admit the possibilities adduced by our correspondents; one of them, the *Tailor and Cutter*, going so far as to endorse the decision of Mr. M. Finlay, never to buy garments from any maker unless knowing the conditions under which the work is executed. "We wish others," it states, "would follow this gentleman's example, and we should soon find workshops would not only get more healthy clothing, but the rank and file of tailors would get more vigorous as the result of better sanitary conditions under which they work." It is a striking comment on the correspondence in question that last week a case was heard at Worship-street wherein the dangers referred to were exemplified in a startling manner. A person named Cohen, residing in the savoury district of Spitalfields, was summoned for unlawfully removing without disinfection certain clothing which had been exposed to infection, and it transpired in evidence that while the defendant's wife and children were suffering from small-pox, in the same room was a quantity of calico in process of manufacture into ladies' underclothing. The technical offence consisted in the removal of the clothing by defendant, but what became of it—whether it was taken to the retailer to be sold or not—did not transpire. If such was the case it is not difficult to foresee a risk to the community, the seriousness of which it is impossible to minimise. It has been demonstrated by experiment that the germs of disease will live in clothing for an indefinite period, and when it is borne in mind that there are hundreds of outworkers engaged in the occupation of making clothing in districts of the metropolis where insidious disease such as consumption is prevalent, it is not difficult to concede that the spread of infection from these sources may be far more common than is generally supposed. Dr. Anthony Roche, lecturing at Dublin on the evils of sweating, expressed the opinion that sweating opened the door for the spread of consumption in the families of those who bought, used, or wore clothes, manufactured under a sweating system, and this opinion is endorsed by the medical profession generally. There is no gainsaying the fact that the present system of inspection is totally inadequate to protect the public against the risk of infection. And yet the remedy would seem to be simplicity itself. The institution of properly ventilated workshops under efficient supervision, and the complete abolition of sweating dens are, in our opinion, the only measures to meet the case. It matters little whether the workers demand it, the question is one that concerns the health of the public, and as such should receive the attention it deserves at the hands of the Public Health Authorities. We fail to see why the man who sells infected clothes should be less liable to punishment than the man who sells an adulterated article of food; in fact, of the two, we consider the former far more criminally involved. Until factory inspection is made more rigid, and the condition under which outworkers labour is either ameliorated or made impossible, it is hopeless to expect a diminution in the statistics of infection; and it is little short of idiotic to din

the open-air treatment of consumption into the ears of the public, while clothing is allowed to be manufactured in dens in which the germs of the disease are harboured, and from which they are disseminated wholesale, no one knows whither. The question is one we should like to see taken up by influential journals which reach the public eye. But if in the meantime we can only impress its importance upon those officially responsible, we shall, at all events, feel that we have done our part as befits a journal that has worked incessantly for the past twenty-six years in the cause of the public health.

The Concentration Camps.

THE subject of the condition of the concentration camps in South Africa has unfortunately recently entered so heated a political atmosphere that in a strictly non-political journal we feel some delicacy in approaching it, even from a sanitary point of view. And yet it is a question of such grave sanitary importance at the present moment that it is difficult for us to pass it over. It is sincerely to be regretted that the question should have become a theme for party wranglings, for we are convinced that the one desire of the country at large is to deal with the question in the broadest humanitarian spirit. During the past week two reports have been published on the condition of the camps, the one by Miss Emily Hobhouse, and the other through the agency of the *Times*. Making every allowance for the possibility of bias on the part of the witnesses, on the one side or the other, it is unquestionable that these reports are very painful reading, and reveal a state of things which is very serious. The one outstanding feature is the very high rate of mortality. The average for all the twelve camps is stated by the *Times* correspondent to be 116·76 per thousand. In the camp at Bloemfontein it is stated to be as high as 383·16, which is more than double the rate which obtains in the highest of others. The figures, it must be admitted, betoken a very grave situation. We are assured that this high death-rate is due to various special causes, such as an epidemic of measles among the children, that the Boers have been unused to living together in large numbers, and their lack of appreciation of ordinary sanitary precautions which are familiar to Englishmen. We are also told that the death-rate is now rapidly decreasing. Of course, it must at once be recognised that the conditions are altogether exceptional. The administrative Authorities are labouring under the greatest difficulties. There are difficulties of supply and transport, with a limited railway service, difficulties of feeding, clothing, housing, and giving medical attendance to the great crowd of refugees —there are now about 25,000 refugees gathered in the camps—and many others. With regard to medical attendance, we are glad to learn that the Executive have *carte blanche* in this respect, and that in addition to the medical staff already on the spot, eight medical men and eighteen trained nurses are now on the passage from England to relieve the officers of the Royal Army Medical Corps at present doing duty in the camps. The questions of medical care and hospital accommodation are of first importance. Then there is the question of efficient sanitary administration. All these, we trust, the Government will not be backward in dealing with in accordance with the exigencies of the situation. A certain degree of hardship and suffering is, of course, in the circumstances unavoidable, but we trust that all that can be done to mitigate it will be done, so as to uphold the character of the nation for humanity.

A New Model Milk Clause.

A NEW clause relating to milk supply for towns was inserted in the House of Commons last week in a Bill promoted by the Brighton Corporation, and as it is to form a precedent, it is of some public importance. The clause provides that if a Corporation makes an order prohibiting any milk being sent into the city without due cause, or unreasonably refuses to withdraw an order, any dairyman, if not himself in default, shall be entitled to recover from the Corporation full compensation for any damage he may have sustained. Mr. Jeffreys, who moved the insertion of the clause, asked that in the interests of the public health a similar clause should be inserted in all future municipal Bills. Mr. Grant Lawson, on behalf of the Local Government Board, accepted the clause proposed, remarking that the Board thought it desirable that in the interests of public health town and country should work together. He also gave an assurance that the Local Government Board would use their influence towards the insertion of a corresponding clause in other municipal Bills. We are not sure whether it is under this clause or not—the parliamentary report not being very explicit—but we understand that the Government have also decided to insert a model clause in such Bills giving an aggrieved farmer the right of applying to the Board of Agriculture for the appointment of an arbiter. Anything that will reduce the tendency to friction between Urban Authorities and the milk industry will be welcomed.

Prospective Changes in the Vaccination Laws.

THERE are two directions in which attempts are being made to have the Vaccination Laws amended. The one is shadowed in a new Bill introduced by Mr. Channing, which seeks to declare that no prosecution under the Vaccination Acts shall be commenced without the authority of the Guardians. In view of the recent history of the Vaccination Act in some parts of England, the object of this measure is sufficiently apparent. The other proposed amendment of the law is of a totally different character, and owes its inception to Sir Henry Littlejohn, the energetic Medical Officer of Health for Edinburgh. It is to provide for the re-vaccination of all persons every ten years. Sir Henry brings forward this proposal in a special

report prepared by him for his Public Health Committee on the recent small-pox epidemic in Scotland, so far as it affected Edinburgh. This report contains some interesting information. It mentions the fact that when Edinburgh was threatened with an outbreak of small-pox, the Corporation at once took steps to prevent it by urging on all classes of citizens the necessity of re-vaccination; and so successful were their precautions that the town escaped the epidemic. During the whole of last year and up to the present time only ten cases of small-pox had occurred in the city, and of these only seven could be attributed to infection received in this country, the other three cases being traceable to abroad. But this comparative immunity was not achieved without cost. The total number of persons re-vaccinated during the critical period was 29,903, and this at a cost of £3207 0s. 6d. In order to prevent the recurrence of these expensive scares, Sir Henry Littlejohn goes on to say that he believes the time has now come, and that the country is sufficiently educated to approve of the passing of a Re-vaccination Act, and he considers the present juncture specially suitable and appropriate for such a purpose. Acting on this report, the Edinburgh Public Health Committee have agreed to recommend the Magistrates and Town Council to memorialise the Secretary for Scotland, asking the Government to take in hand the necessary legislation.

Amateur Investigators.

Many a good cause is injured by the ill-considered enthusiasm and advocacy of its friends, and often much-needed sanitary reforms are hindered or postponed because of the extravagant statements of self-constituted inspectors and would-be reformers. These people do not go about their work with the idea of finding out the true condition of affairs; but before they commence they have resolved that certain conditions prevail in given districts, and this they set out to prove at all costs. One house is dirty —therefore the whole neighbourhood must be the embodiment of filth. They come across an overcrowded room, and immediately it is proclaimed that this is the condition of all the tenements of the district. They condemn the landlords and tenants alike; the Local Authority is denounced as incompetent, and the Health Officers as doing everything else but their duty. All this kind of thing makes very good copy for the sensation-loving Press, but it gives little help to the cause of reformation. There is a vast difference between a "legal nuisance" and the fancied one of the "amateur" inspector, and if the latter would but take the trouble to make himself acquainted with some of the difficulties surrounding the administration of sanitary law, he would not be so fast in charging officials with neglect of duty. Medical Officers of Health, Surveyors, and Inspectors of all kinds are but human, and when their character is impugned they are bound to defend themselves. If, instead of rushing into print, people who see what they deem to be irregularities would quietly report the same to the proper quarters, the remedy might be quickly and effectively applied. But this they will not do, and their self-imposed zeal is so much energy wasted. The last thing the "man in the street" will do is to help a public official, be he health officer or even a policeman, to defeat wrong doing of any description.

The New Regulations at Bombay.

As might have been expected, the proposed regulations of the new Health Officer at Bombay are not to be allowed to go unchallenged. In the issue of the *Times of India* for June 1st there appears a long article, in which the policy of appointing properly qualified Sanitary Inspectors is seriously questioned. The plea set forth is that the conditions of life and the habits of the people are so different in the East that, given a good Health Officer, under whom shall serve a number of thoroughly efficient and well-trained divisional Health Officers, the work of inspectorship might be carried on by "men of the type of retired military sergeants, police officers, &c." We fancy we have heard this kind of argument at home, and to the sorrow of many places it was acted upon some twenty or thirty years ago. Military training is not always the best preparation for the delicate and important duties to be performed by workers in the public health service. They become so bound up with almost mechanical routine, and so imbued with the idea that everybody must bend an unquestioned obedience to their commands, that they cannot adapt themselves to more pacific and tactful courses of administration. It is too late in the day to argue that "anyone" can be a "Sanitary Inspector." The unskilled man is as big a nuisance in the health service as he is in every other industry. Further, are we for ever to rule India by military methods? Have the educational and social efforts of the past half-century been for nought? and are the natives still incapable of grasping the elementary laws of local administration? We believe there are signs that the teeming millions of our Indian Empire (especially in the great centres) are awakening to the duties of citizenship, and we hope that the Health Officer of Bombay will be supported in his determination to introduce a truly "civil service" into the municipal life of that city.

Extensions at St. Thomas's Hospital.

More than ordinary interest is attached to the latest extensions inaugurated last week at St. Thomas's Hospital, London. It may be, of course, as Lord Lister said, that many of the improvements introduced may be described as luxuries, and not essentials; but it can only be right that our great hospitals and medical schools should be furnished on the highest and best hygienic principles. He did well to remind the students of the possibility of having to perform operations in out-of-the-way places, and under less favourable conditions; but none would desire that the elements of knowledge and power should be gained amidst such crude surroundings. And, fur-

ther, very often the most highly trained and refined natures are those who can best adapt themselves to less favoured circumstances. But it is not so much to Lord Lister's speech that we desire to direct attention, as to the new operating theatres and children's ward. The latter is tiled with Doulton tiles, and there are twenty-two picture panels in "Under-glaze Faience," representing well-known fairy stories. Iron and glass are used for the furniture and utensils of the ward. The operating theatres are designed for the practice of strict aseptic surgery. The walls are composed of Keene's cement covered with white enamel, with a dado of Marmorite—a form of tough opaque glass which offers a very smooth and easily-cleaned surface. Terrazo pavement forms the floor, which is on a slight slope, so that the whole place can be thoroughly flushed with water. The auditorium is in four raised tiers, made solid of white marble, skeleton staging having been rejected on account of the difficulty of keeping it adequately clean and free from dust. The furniture is wholly of glass and iron. The subsidiary rooms, which are finished in the same style as the operating theatres themselves, include anæsthetising rooms, a sterilisation room, where there is a high-pressure steam steriliser for dressings, and a water steriliser for the supply of germ-free saline fluid, a surgeon's room where the surgeon removes his boots and outer clothing and substitutes for them clean boots and sterilised blouses, so that no dirt is taken into the theatres, a recovery room for patients, &c. Ventilation is effected on the plenum system. Air, adequately warmed and forced through filters, is pumped in by rotary fans; the pressure in the rooms is thus always slightly greater than it is outside them, and therefore there is no fear of unfiltered air passing in through crevices or an open door. In short, every precaution has been observed to ensure that perfection of cleanliness which is the essence of aseptic surgery.

In Monday's *Times* Dean Fremantle calls attention to what is perhaps the worst feature revealed by the recent census, viz., the decrease in the birth-rate in the United Kingdom. He points out that in the year 1875 there were born in the United Kingdom 35 children for each 1000 of the people. In the year 1900 they are only 29. That is, for every 1000 of our 41½ millions there are now born six fewer than twenty-five years ago; and this means a loss of 249,000 children for each year. This is a new and strange phenomenon in England; but, what is still more startling, it implies a much more rapid decline of the birth-rate than that of France, where the process has gone on gradually throughout the century. "What," asks the Dean, "is the prospect which this diminution opens to us? If it continues in the next twenty-five years it will have come down from 29 to 23 per 1000; and in less than fifty years from this time it will have been reduced to 17, the lowest figure which we can imagine the death-rate to reach. There will then be no increase of the nation, but as now in France, the prospect of actual diminution. But there is more than this. The process has hitherto affected only special parts of our country. In London the annual birth-rate is about 29 per 1000; in Westmoreland it is about 20. At Gateshead it stands at 33; at Huddersfield at 22. In the latter town, though it is a flourishing manufacturing centre, there are actually 400 fewer people in 1901 than there were in 1891, and the School Board cannot fill their schools." Dr. Fremantle is not alone in his alarm at this phase of our national life. But the question is so many-sided that we are not surprised it is so little discussed. Perhaps the worst feature is the growing disposition on the part of women to avoid the responsibilities of motherhood.

Two excellent appointments were made last week by the City Corporation. First, Dr. Williams, who has acted for the past nine years as Chief Boarding Officer at Gravesend, and had charge of the hospital at Denton for the Port Sanitary Authority of London, was promoted to the position of Medical Officer for the Port of London in succession to Dr. Collingridge. In these positions Dr. Williams has proved himself a most efficient officer, and the City is fortunate in being able to secure one so thoroughly acquainted with the work to be done. The second appointment was that of Dr. F. J. Waldo as City Coroner. This gentleman is well known to our readers. Until the creation of the new London Boroughs, in addition to being Medical Officer for the Inner and Middle Temples, he was Medical Officer of Health for the district of St. George the Martyr, Southwark. In the latter position his conscientious devotion to duty was unpalatable to many of the members of the old Vestry, who would have liked him on more than one occasion to "re-write his reports," because they revealed the existence of unsatisfactory conditions. In his new position we believe that Dr. Waldo's sterling ability will receive a better recognition, and his training as barrister and doctor supply the combination needed to properly carry out the duties of Coroner.

The report just issued by the directors of the Oxygen Hospital covers a period of two years. In 1899-1900 the admissions were not so numerous as previously, the cases already in the hospital being of long standing and taking a proportionately long time to heal. In 1900-1901 the numbers admitted were up to the average, but owing to a falling off of income many deserving cases were necessarily refused. Eighty-one cases were treated during the year, fifty-nine were discharged, and twenty-one remained in the hospital. The income fell to £944 from £1588 in the previous year. The report states that a letter has been received from the Guardians of the Poor of the Parish of Willesden expressing gratification at the excellent results of the treatment of cases that had been sent by them. We are also told that the treatment of lupus had proved entirely successful, cases previously regarded as hopeless having been cured. In view of the treatment of diseases of the lungs it is proposed, when funds permit, to erect cubicles in which the patients can be placed

and supplied with dry, purified, super-oxygenated air. For this purpose at least £200 is needed. The Duke of Argyll presided last week at the annual meeting, and claimed that the hospital could show 90 per cent. of cures, while the cost of maintenance was only 27s. per patient, including 2s. 6d. each for oxygen.

Staines is fast becoming quite a picnic resort for engineers and others connected with waterworks. Last week another party paid a visit to the great reservoirs there, to inspect the progress of the works. The directors of the water companies, their engineers, and contractors, were all congratulated on the advance made, which is considerable since the last visit. Some idea of the size of the reservoirs will be gained when it is known that their circumference is four and a-quarter miles, and that they are one and a-quarter mile long by five-eighths of a mile at their northern end, and nearly a mile wide at their southern end. The embankments vary from 21ft. to 35ft. in height, and are formed of the excavated material with a thick bank of puddled clay in the centre. Inside, the slopes are being thickly lined with concrete to a depth of 15ft., and it is expected that the larger reservoir will be completed during the present year, and the smaller one in the course of next year.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

The vacant appointment of Engineer and Surveyor to the Borough Council of Hampstead, caused by the retirement of Mr. Chas. H. Lowe after a long period of service, has been filled by the election of Mr. Oliver E. Winter, Borough Engineer and Surveyor of Poplar, out of eighty candidates. Mr. Winter is well known to his brother engineers as an unobtrusive, genial, and capable engineer, and he has our hearty congratulations on his appointment. The Borough Council of Hampstead will have no reason to regret their judicious choice of Mr. Winter.

I would remind surveyors of districts who are responsible for the supervision of trees in public streets that during the months of July and August the roots of such trees should be watered, or many will be lost through drought. The simplest and most effective method of doing the work is to remove the gravel for a depth of several inches round the base of the tree, forming a hollow or dish into which the water should be run by a hose attached to a street-watering van. The watering should be effected once a week during a continuance of dry weather.

Referring to trees in streets, I would point out that the practice of surrounding such trees with wrought iron tree guards, and iron grids around the base is being generally discarded as both expensive and unnecessary. All that is really requisite is to encircle the tree with galvanised wire netting of 1in. mesh, fastened with ordinary wire, and, when the trees are young, support them with poles known as "ricker poles." Once a year the wires should be examined, released where there is a danger of their cutting into the bark, and again re-fixed. The work can be carried out by any intelligent labourer, but where trees are numerous it is advantageous to employ a man who has served some time as a gardener, who can judiciously trim and lop trees at the necessary and proper seasons, and so preserve their symmetry; for it is suggestive of bad administration that such trees should be allowed to grow as they listeth, as one sees them in some districts, and instead of being ornamental are ugly, and obstruct air and light from houses, and also the light from street lamps.

I am confident that all those Municipal Engineers who have at any time met Major-General Carey, the Chief Engineering Inspector of the Local Government Board, will regret that he has retired from the position. His courtesy and conduct to engineers who had at any time to meet him in the offices at Whitehall were always those of a soldier and a gentleman, and his knowledge of municipal engineering, although himself a Royal Engineer, was sound and reliable, and his advice and assistance could always be depended upon. He has our good wishes in his well-earned retirement.

Major-General Crozier succeeds General Carey in the post of Chief, and Mr. G. W. Willcocks as Deputy Chief Engineering Inspector. Mr. P. Gordon Smith has retired from the post of Architect to the Local Government Board, and Mr. Brook Taylor Kitchin, Deputy Chief, has been appointed to succeed him. As Architect to the Local Government Board, one of his duties is to advise the Board on all building bye-laws submitted for approval, and Mr. Kitchin's intimate knowledge of them is a matter for admiration. He has the advantage of having served under Municipal Authorities, and having acted as Building Surveyor where the execution of the bye-laws as to new buildings was entrusted to him, and he has on more than one occasion related to me his experiences with that well-known individual the jerry-builder, who, however, rarely succeeded in evading his watchful eyes. Mr. Kitchin is thus peculiarly well fitted for the post to which he has been appointed, and his practical knowledge will stand him in good stead.

The shareholders of the Welsbach Incandescent Lighting Company have fallen on evil times. There is again no dividend forthcoming, as appears from the annual report just issued for holders of both the ordinary and preference stock, notwithstanding that there has been an increase of 75 per cent. in the number of burners, and of 46 per cent. in the number of mantles sold, the total sales exceeding that of any other year. The affairs of the company were at one time buoyant and *débonnaire*, but it is doubtful whether they will ever return. The fact appears patent that over-capitalisation is one of the causes of prostration, for the preference stock represents £1,500,000, the ordinary stock £1,350,000, and the deferred shares £629,500, yet none of these receives any dividend. And yet I am bound to say that at no time were the company's burners in more general use for public street lighting than now. Amongst the class of low-pressure incandescent burners the Welsbach burner is pre-eminently the best, and the Welsbach anti-vibrator for street lamps is unequalled, although there are several others on the market which are running them closely.

Whether the present management of the company will make up the ground lost by the bad and unpopular management of their predecessors is difficult to forecast. Their methods in the past caused them to incur the odium of tradesmen and all who had to do business with them to a degree which was most detrimental to the company, and was due in part to the knowledge that their products were a monopoly, and also to an unacquaintance with English business methods. It

would be interesting to know how many thousands of pounds have been spent by the company in litigation.

THERE was another company—the Voëlcker Incandescent Lighting Company—promoted a few years ago, which threatened to enter into competition with the Welsbach Company and sell burners and mantles at about half the price of those of the latter company, but of which little has been heard of late. There are some surveyors and public officials I know who would also like to make its acquaintance. But I doubt whether they are entitled to any sympathy. The *modus operandi* of the promoters was to enlist the active support of the Surveyor to the Local Authority in various towns in the mantle and burner which they produced—but which they were unable to sell, owing, it was said, to their being infringements of the Welsbach Company's patents, but which patents it was stated would shortly expire—and then hold a small public exhibition ostensibly to show the new burners, but mainly as a means of obtaining shareholders. The plan succeeded, and numerous shares were taken, especially by public officials, who fell before the bait offered of about twenty-five shares thrown in gratis for every five paid for. One would have expected surveyors, at least, would have discerned the unsubstantiality of a concern which could throw away shares with such profligacy; but they didn't. SENEX.

Public Works.

SEWERAGE.

THE Oldbury Urban District Council has decided to borrow £18,000 for the reconstruction of sewers in the district.

THE Mytholmroyd District Council has decided to borrow £13,184 from the Public Works Loans Commissioners for sewerage purposes.

THE Bourne (Lancs) Authority has decided to convert its existing sewage works to the Natural Purification Company's system (Cosham's patents,) the contractor having received orders to commence at once.

THE Heavitree District Council has decided to apply to the Local Government Board for leave to borrow the sum of £3500 for the purpose of providing an outfall sewer for the Polsloe Priory Estate, also that application be made for leave to borrow £2500 to pay off the existing mortage of that amount on the sewage farm, Worford.

A LOCAL Government Board inquiry was held last Friday at King's Heath Institute by Colonel W. R. Slack, R.E., respecting an application made by the Urban District Council of King's Norton and Northfield for sanction to borrow £3558 for works of sewerage. It was proposed to effect a re-construction of defective sewers at King's Heath, Moseley, Selly Park, and the Cotteridge at a cost of £615 10s., the introduction of an improved sewer ventilation throughout the whole of the Council's sewerage system within the Tame and Rea drainage area at a cost of £1812, and the carrying out of a scheme of improved sewer flushing at a cost of £1130. The system of ventilating the sewers by means of open gratings in the surface of the streets was found to be imperfect, and periodically led to complaints from residents in various parts of the district. Dr. Hollinshead said there had been a great deal of illness in the district; whether it was due to the open gratings he could not say. There was no opposition to the application, which it was pointed out was of great importance to the health of the district.

COLONEL A. G. DURNFORD, R.E., conducted an inquiry at Radcliffe-on-Trent last week with respect to the application of the Rural District Council of Bingham for sanction to borrow £8050 for the purpose of sewerage and sewage disposal for the parish of Radcliffe.

AT a recent meeting of the Leeds Sewerage Committee, it was intimated that the chairman of the Committee (Alderman Harding) intended calling a special meeting at an early date to consider the whole question of the disposal of Leeds sewage. Under these circumstances it was decided to visit the Knostrop works on the same day as the special meeting.

FURTHER evidence was given last week before the Select Committee of the House of Commons presided over by Mr. Bill against the proposals of the Derby Corporation for extension of the borough boundaries, the execution of sewage works, &c. The Chairman, in the course of the evidence, said that the Committee was impressed with the feeling of the neighbourhood against the establishment of the works. Mr. Baldwin Latham, C.E., the well-known authority on sewage questions, condemned the scheme proposed by the Corporation. The whole of the district proposed could not be drained by gravitation into the sewers, the site was ill-chosen, and the character of the soil not suitable for sewage works. Mr. Hugo Young, K.C., after speaking against the proposal to extend the tramways in the direction of Darley Abbey, called witnesses on behalf of the Shardlow union, Mr. Edwin Conner, J.P., chairman of the Rural District Council, stating that the district was unanimous against inclusion of the proposed areas, and that their affairs were already well managed. Dr. Hogg, the Medical Officer for the district, also gave evidence in opposition to Derby's proposals, stating that there was no reason, from a sanitary point of view, why the outside districts should be annexed to Derby. Mr. Freeman, K.C., having addressed the Committee in support of the Shardlow Rural District Council, the Committee again adjourned.

AT a recent meeting of the Alnwich Urban District Council a report upon the sewage dispossl of Canongate, where a system of sewerage purification is in operation, was received from Dr. Hembrough, Medical Officer of the County Council, who had made an inspection recently. The report briefly was to the effect that the sewerage of Canongate is, and had been for a long time, in a most unsatisfactory condition. The rest of the sewerage of the town of Alnwick was drained to the new sewage disposal works, including 4·5 acres of land for broad irrigation, opened in 1897. The prospect was then held that the necessary alterations in the sewerage of Canongate would be undertaken, but nothing appeared to have been done beyond the removal of obstructions that had from time to time arisen; the substitution of a few socketed pipes for some of the butt-jointed pipes laid down forty years ago or more. In the course of the low-level intercepting sewer were placed two catchpits, and the proportion of sewer extending from the first catchpit above the Lion Bridge to 250 yards above Denwick Bridge appeared to be in a bad condition, and the appearance at each outfall above and below the Lion Bridge could only be described as disgusting in the extreme. In spite of daily attention and considerable yearly expense, the sewerage system for the Canongate portion of the town was a distinct failure as regarded purification of sewage, and a most prominent instance of river pollution was here to be found, by the river having no rapidity of flow and eight weirs being constructed between a short distance above the Dairy and the new outfall from the irrigation ground at Hesleyside. The existence of these weirs in so short a stretch of river emphasised the necessity of all impurities being excluded by every possible means. It was agreed to refer Dr. Hembrough's report to the Sewage Disposal Committee for consideration, and report thereon.

A LETTER has been received by the Tutbury Rural District Council from the Local Government Board with reference to the proposed sewerage and sewage disposal scheme of Barton-under-Needwood, and inquiring into the present position of the matter. It was resolved to approach Sir Reg. Hardy as to what terms he would sell on lease the land to the Council. The Clerk was instructed to inform the Local Government Board as to what was being done.

IN accordance with the requirements of the Public Health Act of 1875, the members of the Builth Wells Urban District Council have applied to the Local Government Board for permission to borrow £1288. This money is to be devoted to street improvements, including the main roads, the culverting of Gloewbrook, and sewerage improvements. The Local Government Board has directed an inquiry into the subject matter of the application, and Inspector E. A. Sandford Fawcett, A.M.I.C.E., will attend at the Magistrates' room, Builth Wells, in the forenoon of Friday, the 28th inst. The object of the public inquiry is to receive the evidence of any persons interested in the matter of the aforesaid improvements or expenditure.

LAST week a meeting of the Armagh Urban Council was held, when the engineer in charge of the sewerage scheme, Mr. J. Finlay Peddie, C.E., Belfast, and the consulting engineer, Mr. J. Kaye Parry, C.E., Dublin, were present. A long discussion took place regarding the connecting of existing sewers and drains with the works at present being carried out in the city. Mr. Kaye Parry was asked for his opinion regarding these connections, and also regarding the carrying away of surface water. He contended that a considerable responsibility in the matter lay on the owners of houses to see that their sewers were connected with the new scheme, but he said in the case of a sewer connecting several houses he thought the Council would be liable to see to the connection. He approved of Mr. Peddie's idea in not duplicating the system in order to carry away surface water, as, in his opinion, that would have been a very expensive undertaking, and he suggested that in all cases where surface water had to be taken away special arrangements should be made, so as to prevent the surface water getting into the pipes laid for the sewage matter alone. A long discussion took place regarding the disposal works to be adopted by the Council. Mr. Parry made a statement, and produced plans of disposal works by Adams's installation. He showed that, under the original scheme, the septic tank was a closed one, and he drew a comparison between the open and closed tanks, showing that no provision was made for the cleaning out of sludge in the closed tank, and that in the plan of an open tank submitted by him arrangements were made for the removal of sludge. Coming to figures, Mr. Parry showed that roughly the cost of the original scheme, including the royalty of £1000, was £4085, and that under his scheme, which included Adams's installation at a cost of £450, the total outlay would be about £4500, but they would have almost three times the capacity. After hearing Mr. Parry's statement the following resolution was unanimously adopted :—" That having heard the lucid statement of Mr. Kaye Parry, C.E., our consulting engineer, upon a disposal works scheme, sketched plans of which he has submitted to us, and as he has agreed to give the substance of his statement and the financial portion of it in writing, we hereby approve of the scheme which he has submitted, and adopt it for the Armagh disposal scheme, and request Mr. Parry, C.E., to prepare the plans and specifications necessary, and also to prepare plans for the Local Government Board with as little delay as possible, and should the cost of said work exceed the balance, £2000, that we approve of an application being made for a sum over and above same not to exceed £2000."

WATER.

IT is estimated that the Leeds waterworks will yield a clear profit of £10,000 for the year.

THE Whitehaven Rural District Council requires a loan of £450 to enable it to lay down water mains at Sandwith.

MESSRS. JAMES SCOTT AND SON, Aberdeen, have received the contract for the erection of a new water reservoir at Strichen. The contract price is £139 12s.

THE Dronfield Urban District Council has agreed to apply to the Public Works Loan Board for a loan of £2500 at 3¼ per cent., repayable in three years, for the purpose of providing a water supply.

THE Law and Finance Committee of Greenock Water Trust has approved a recommendation to purchase, for the sum of £1110, the millstead of Messrs. Mackenzie and Walker, Shawswater Grain Mills, Dellingburn-square.

A SPECIAL meeting of Scarborough Rural District Council was held last week for the purpose of executing the deeds of mortgage relative to the East and West Ayton water supply. The amount of the loan was £2600, apportioned between the townships, East Ayton being chargeable with £1100 and West Ayton £1500.

THE Epping Urban Council has unanimously decided to appeal to the Local Government Board for advice in the water supply difficulty. For some time complaints have been rife as to the insufficiency of water. The Council complains that the Herts and Essex Water Company continue to extend the mains without providing an adequate supply of water.

A PUBLIC inquiry has been held at the Maldon Workhouse by Col. W. Langton Coke, M.I.C.E., one of the Local Government Board Inspectors, with reference to an application by the Maldon Rural Council for sanction to borrow £2800 for purposes of water supply for Althorne, Cold Norton, Hazeleigh, Latchingdon, North Fambridge, Purleigh, Stow Maries, and Woodham Mortimer.

THE Thurso Town Council, after years of discussion, and many attempts to stave off the pressure put upon it by the Local Government Board, at a special meeting last week, took the first steps to solve the question of augmenting the water supply of the town, and providing an adequate drainage scheme. By a large majority, it was agreed to employ Mr. David Reid, C.E., Inverness, to visit the town and report as to the best method and the probable cost.

NOTWITHSTANDING the large and increasing demand on the part of the public at this time of the year for street and garden watering and for sewer flushing, it is satisfactory that the level of water in the Winchester Water Company's deep wells has maintained a daily average of 20ft., and this notwithstanding that the daily supply fram the water mains amounts to forty gallons per head of the population of the city. Recent analyses prove that the water of the Winchester Company retains its noted purity and excellence.

AT the last meeting of the Helston Rural District Council, the Local Government Board wrote asking to be informed of the position of the water supplies for Kennegie, Germoe, and St. Keverne, and the insanitary condition of the latter place. It was decided to reply that the first-named matter was receiving attention. With regard to the St. Keverne water supply, the Inspector, Mr. Joyce, was asked to meet the Water Supply Committee of the Parish Council and report the result of the consultation to the Council. The analyst's report on the water at Porthallow being unfavourable, the Council, on the recommendation of the St. Keverne Committee, decided to fork the water out of the well, and have another sample taken in a month's time.

Of the 460 samples of impounded and filtered water supplied to London examined bacteriologically during May, 70 samples, or 15·2 per cent., were sterile.

The Waterworks Orders Confirmation (No. 1) Bill came last week before the Select Committee of the House of Lords, over which Lord Harris presides. The object of the Bill is to confirm certain Provisional Orders made by the Board of Trade, one of which enabled the South Staffordshire Waterworks Company to raise new capital. This latter Order was opposed by the Kingswinford Rural District Council.

With reference to the recent complaints from Newport as to an inadequate water supply, the Water Engineer reports to the Water Committee of Dundee Town Council that the work of scraping the Newport main from Wormit reservoir to Cupar-road has been finished, that the operation has been very successful, and that there is now an adequate supply at the higher terraces. He also reports that the cost of the work has only been £108, against an estimated cost of £135, and that the scraper might be passed through the main at any future time at a cost of about £5, or even less.

The Prestatyn Water Bill, which seeks to authorise the Urban District Council of Prestatyn to purchase the undertaking of the Dyserth, Meliden, and Prestatyn Water Company, and to construct additional waterworks for an increased supply, came last week before a committee of the House of Commons, over which Sir John Brunner presided. The Bill has already passed the House of Lords. Lord Windsor, the Ecclesiastical Commissioners, and Mrs. Conwy, owners of property affected by the Bill, opposed in that House, and clauses were inserted which satisfied Lord Windsor and the Commissioners, but not Mrs. Conwy, who again petitioned against the Bill.

Last week, at Webbington, Mr. G. B. Sully, chairman of the Burnham Urban Council, officially turned the water into the new mains, which have just been laid between Webbington and the pumping station, Brent Knoll. Mr. W. J. Press, of Burnham, is the engineer, and the present scheme is to prevent the waste for the future of 70,000 gallons of water daily, by providing an additional 8in. main. Eventually Mr. Press's scheme provides for bringing the whole of the supply of water at Winscombe to Burnham, by placing a new 12in. main to Webbington, when both the original 6in. main and the new 8in. main will be fully utilised. After the ceremony, Mr. Sully entertained the company to luncheon at Brent Knoll. Mr. W. H. Smith, of Clifton, is the contractor for the present scheme, which has cost £4500. The mains are arranged to cross the river Axe upon steel girders.

The Waterworks Committee of the Leeds Corporation met last week, when it was decided to lay a 10in. main from Victoria-road, Headingley, to Woodhouse Moor Police-station, and generally increase the water supply in the neighbourhood. This main will serve the Yorkshire College. It was further decided to lay a 24in. main from East End Park to South Accommodation-road, the tenders of the Staveley Coal and Iron Company for casting the pipes, and of Messrs. Young, of Cullingworth, for carting and laying the pipes, being accepted. The City Engineer (Mr. Thomas Hewson) reported that the 30in. main from Eccup to Swinsty had been laid for a distance of 8104 yards, the total length being 20,530 yards. An agreement had been entered into with the Great Northern Railway, enabling the Corporation to complete an 18in. main from Woodhouse to Wortley reservoir. It was also announced that the reservoirs in the Washburn Valley contain 94 days' supply of water—with a daily requirement of 27,000,000—as compared with 73 days' supply—with a daily requirement of 26,250,000 gallons—at the corresponding period of last year.

LIGHTING.

The Otley Gas Bill has been read a third time in the House of Commons.

The South Metropolitan Gas Bill has been read a second time in the House of Lords.

The Chester Gas Bill, for confirming further powers upon the Chester United Gas Company, has passed the Chairman of Ways and Means as an unopposed measure. It will be sent for third reading in the Commons. It has passed through the House of Lords.

The South Metropolitan Gas Company gives notice that, concurrently with the reduction of the standard illuminating power of gas from sixteen to fourteen candles, from the 1st prox., the price charged for gas to consumers will be reduced 5d. per 1000ft., namely, 2s. 8d. to 2s. 3d. per 1000 cubic feet.

The Local Government Board holds an inquiry to-day at Bath into the application of the Bath Surveying Committee for sanction to borrow £1200 for wood paving and street improvements. The Committee intend to apportion £550 for repairs to the bridge at Abbey View, and £650 for wood paving. An inquiry is also to be held at the same time into the application of the Electric Lighting Committee to borrow £4000 for the purposes of electric lighting.

For some time the question of giving the Thornton Heath Baths the benefit of the electric light has been under consideration. It has at last been decided to introduce it to the swimming bath, and public hall, and the drying and store rooms. This will not only be a great improvement as regards convenience, but will very materially conduce to public safety. Tenders have been invited for the work, and if it can be given into local hands so much the better.

The Poulton Gas Bill, which has already passed through the House of Lords, came, on Thursday, as an unopposed measure before Mr. W. J. Lowther, Chairman of Committees, in the House of Commons. The object of the Bill is to provide for the transfer of the undertaking of the Poulton-le-Fylde Gas, Coal, Lime, and Coke Company to the District Council, and to authorise that Council to supply gas, and for other purposes. Various verbal amendments having been made, it was allowed to pass the committee stage, and in due course will be reported for third reading.

A Bill to confirm certain Provisional Orders made by the Board of Trade, under the Electric Lighting Acts, 1882 and 1888, came last week before the Examiners of the House of Lords for proof of compliance with the further Standing Orders, the measure having been already passed by the House of Commons. Amongst others was one enabling the District Council of Trowbridge to supply electricity within their area. There was no opposition at this stage, and the necessary formal proofs having been given, the Bill was ordered to be reported for second reading. Mr. Stevenson, the engineer or adviser, appointed by the Council, has been in Trowbridge conferring with the Electric Light Committee.

The electric light was formally inaugurated at Keighley by the Mayoress on Saturday, the 15th inst. Two powerful engines and dynamos were started by the Deputy-Mayoress and Mayoress, whilst Mrs. W. Clough set the electric motors in motion from the switchboard. Alderman B. S. Brigg, in tendering thanks to the Mayoress, remarked that he believed it was nearly three-quarters of a century ago since—not perhaps on that identical spot, but within a very few yards of it—their forefathers wisely established the gasworks. The Mayor also said a few words, and took the opportunity of acknowledging the services of Mrs. Brigg and Mrs. Clough. The party subsequently made a tour of inspection through the works, under the guidance of Mr. J. M. Smyth, the Electrical Engineer.

The Stafford Corporation finds it necessary to spend £7000 in gasworks extensions.

Mr. M. K. North, A.M.I.C.E., one of the Local Government Board Inspectors, held an inquiry at Beckenham recently into the application of the Council to borrow £20,000 for the extension of the electric light at Beckenham, £780 for purposes of street improvement, and £275 for the public baths.

The Stroud Gas Bill, which has already gone through the Commons, has passed the House of Lords Committee on unopposed measures, and has been sent for third reading in the Upper Chamber. The Bill authorises the conversion of the existing capital, and empowers the company to apply for a Provisional Order to supply electrical energy.

GENERAL.

The Bradford Town Council has decided to establish a bacteriological laboratory.

The Salford Corporation has voted a sum of £1200 for the erection of bandstands in four public parks.

The Duke of Bedford, as Mayor of Holborn, laid the foundation-stone on Wednesday in last week of a new swimming-bath in Endell-street, to be erected at a total cost, including that of the site, of £25,000.

Col. A. C. Smith held an inquiry at Farnworth last week into the local District Council's application for sanction to borrow £14,000 for the erection of a Town Hall and public offices in the centre of the town.

At Dudley Town Hall last week Colonel W. R. Slacke, R.E., held an inquiry relative to the proposal of the Town Council to borrow £500 for the provision of public conveniences in connection with the open markets.

Mr. H. Timbrell Bulstrode, M.D., Local Government Board Inspector, held an inquiry at Stanmore recently into the application of the Hendon Rural District Council for sanction to borrow £7500 for the erection of an isolation hospital.

The Chiswick Urban District Council has instructed the surveyor to prepare plans, specifications, and estimates for the erection of an isolation hospital. The surveyor has also been directed to ascertain as to what was the best arrangement for a temporary bath to be erected at some point on the banks of the Thames.

A Board of Trade inquiry has been held at the Warrington Town Hall by Colonel Von Donop into the application of the Warrington Corporation for powers to borrow £66,000 for the purpose of laying tram lines from Sankey Bridges to Latchford Swing Bridge and a branch line from Warrington Bridge to the Swing Bridge, Stockton Heath.

At a meeting of the Birmingham Board of Guardians on Thursday a resolution was passed to appoint a Special Committee of the Board to take into consideration the desirability of erecting a sanatorium for advanced cases of phthisis. It was stated that last year nearly 800 people had died in the city from phthisis, and that in the last ten years no fewer than 8000 had succumbed to it.

Lord Lister, in the presence of a number of gentlemen of the medical profession, last Thursday declared the new wing of St. Thomas' Hospital open for the reception of patients. The new building, which has been erected at the cost of about £20,000, provides the hospital with a children's ward containing sixteen beds, and with two operating theatres, which are probably the most perfect rooms for the practice of aseptic surgery to be found in Europe. In each theatre everything calculated to harbour dust is avoided, and every improvement that ingenuity can suggest as making for cleanliness has been adopted.

A Local Government Board inquiry has been held at Cardiff in respect to an application made by the Llandaff and Dinas Powis District Council for permission to borrow £8500 for the construction of an isolation hospital at Pantawel Radyr.

A Local Government Board inquiry has been held at Swindon, Wilts, to inquire into the application of the Council to be allowed to borrow the sum of £3295 for the purpose of increased water supply, and the sum of £839 for street improvements.

At a recent meeting of the Tottenham Urban District Council the General Purposes Committee recommended the Council to carry out the improvement on the north side of St. Ann's-road, at an estimated cost of £2320, and on the south side at a cost of £760. It was decided to have a special meeting of the Council to consider the tenders in regard to a refuse destructor.

With the object of getting rid of insanitary areas, the Fulham Borough Council has requested the London County Council to include in its next General Powers Bill a provision that all property owners shall, upon request, be compelled to declare their ownership to the Sanitary Authorities and to their tenants. The opinion of the Fulham Council is that much of the slum property is owned by persons in such a position that if they knew that their names could be ascertained and published, they would cause such property to be kept in a more sanitary condition.

Mr. Powderly, superintendent of immigration in the United States, has ruled that tuberculosis is a dangerous contagious disease; and it follows under the general law that consumptives are not to be allowed to land. This drastic ruling, it is said, will be held to apply to ordinary travellers, as well as immigrants, to saloon passengers as well as those arriving in the steerage. Difficulties of detection will probably make the regulation a dead letter for well-to-do travellers; otherwise the heating climates of Colorado and Southern California would actually be debarred them.

The interest shown in the sittings of the Parliamentary Committee on the new Factories Bill, and in legislation dealing with industrial questions generally, has produced many inquiries for works relating to factories and workshops. To meet the demand for authoritative literature on this subject, Messrs. Eyre and Spottiswoode, Government publishers, East Harding-street, E.C., announce the publication of a new edition of Abraham and Davies' "Law Relating to Factories and Workshops," corrected throughout, with all the latest rules and orders, and a revised list of cases.

The New Mills Urban District Council's seal has been attached to an agreement with the County Council for the repair of the main roads for £1500. A committee has been chosen to consider the question of a recreation ground for the district. It was reported that the Stockport Corporation had agreed to supply the Council with water in New Mills for an annual payment equal to 4 per cent. on the proportion of capital expended in bringing the water to New Mills. If a lower rate is conceded to the Hayfield District Council the New Mills rate is to be lowered accordingly.

In accordance with a resolution passed by the Salisbury Town Council, tenders have been invited for the supply of a refuse destructor, which will be used in connection with the new sewage works. The following were the estimatss, viz.:—Mr. Hale, £1500; Messrs. Wort and Way, £1488; Mr. Dawkins, £1430; Mr. Hawkins, £1390; Messrs. Kite and Son (accepted), £1355. The tenders for the chimney shaft, 120ft. high and 5ft. internal diameter, are as under, viz.:—Mr. R. Neal, £869; Messrs. Wort and Way, £798; Mr. Hawkins, £685; Messrs. Wilson Bros., Lamplough (accepted), £625.

On Monday the Dowager Lady Tweedmouth opened the dwellings for working classes recently erected by the Bath Corporation at a cost of over £10,000, the project being the first of two important schemes which the Corporation has undertaken. At a luncheon given subsequently by the Mayor, Mr. Silcock, Lord Tweedmouth congratulated the city on its progressive policy, and dwelt on the importance to all sections of the community of the proper housing of the working classes. He thought wider powers should be given to local authorities in dealing with this question.

At the meeting of the Spalding Rural District Council on Monday last a motion was made for the adoption of the Housing of the Working Classes Act in Donington. It was urged that to stop the depopulation of the rural districts revealed by the census better housing accommodation was necessary. Cases were cited of a family of seven living in a house with but one bed-room, and of a man, wife, and seven and eight children in houses with but two bed-rooms, one "not fit for a dog to sleep in." It was believed that the necessary houses could be built with little or no charge on the rates. The Council decided to take steps to use the powers given by the Act.

At the last meeting of the Stepney Borough Council, the Works Committee reported that the Borough Engineer had submitted to them a report on the question of scavenging throughout the borough. This report they had approved, and were of opinion that the principles embodied should be adopted by the Council. They were further of opinion that the difficulty of providing suitable tips for the disposal of rubbish—a difficulty which they apprehended would increase in the future—as well as having regard to the fact that scavenging could be better carried out by the Council than by a contractor who, owing to the varying conditions of the weather, is unable to estimate to undertake the work efficiently, and at the same time guard himself from loss, that the Council should adopt the following recommendations:—(*a*) That the Council adopt the principles of the report and carry out the suggestions contained therein.—(*b*) That the committee is of opinion that the Borough Engineer should get out an estimate of the area required for the purpose of the disposal of refuse in the borough, such area to contain sufficient room for destructor, slop tanks, and electric lighting station, with reasonable provision for extension. (*c*) That this committee is of opinion that the disposal of refuse in the future should be as far as possible by means of destructors, and further that an additional destructor should be immediately provided in the borough. As bearing upon the question of scavenging they submitted the following recommendation:—That the Council do undertake the dusting, sweeping, and watering of the whole of the streets in the borough at the expiration of the existing contracts in St. George's and Limehouse.

PERSONAL.

Dr. Grindrod has been reappointed Medical Officer for Norden.

Dr. W. H. Andrews has been appointed Medical Officer of Health for Modbury.

Dr. Campbell has been appointed Medical Superintendent of the Caterham Asylum.

Mr. E. D. Long has been appointed Electrical Engineer for the urban district of Grays.

Mr. J. W. Sunderland has been again chosen as Nuisance Inspector for Norden.

Dr. J. Taylor has been reappointed Medical Officer of Health for Chester-le-Street rural district.

Mr. W. A. Millward has been reappointed Inspector of Nuisances for Llandrindod Wells.

Dr. J. C. Saunders has been appointed Medical Officer of the Bootle division of the West Derby union.

Dr. Heather has been appointed Medical Officer of Health for Bredwardine, in room of Dr. Featherstone resigned.

The death occurred on Sunday morning, the 16th inst., of Mr. W. O. Hulm, Town Clerk of the borough of Pembroke.

Mr. W. H. Martin, of Newcastle, has been appointed Inspector of Nuisances for Whitley at a salary of £90 per annum.

Dr. Don has been appointed Public Vaccinator for Newcastle-on-Tyne, and Dr. Simpson has been appointed Medical Officer.

Mr. A. Green has been re-elected Medical Officer of Health for Ringwood, and Mr. H. D. Holloway, Inspector of Nuisances.

Dr. Harcourt Gervis has been appointed Medical Officer to the West Hampstead Branch of the Hampstead Provident Dispensary.

Dr. Chas. Harrison has been reappointed Medical Officer of Health, and Mr. T. Brown Sanitary Inspector for Bracebridge for the ensuing twelve months.

Dr. Anderton has been re-elected Medical Officer, and Mr. Chadwick Surveyor and Inspector of Nuisances for the urban district of Ormskirk, at salaries of £50 and £80 per annum respectively.

Dr. Herbert Williams, the senior boarding Port Medical Officer at Gravesend, and Medical Officer of the hospital, has been appointed Medical Officer of the Port of London, at a salary of £650 a year.

Mr. James Dodd, Assistant Sanitary Inspector to the Borough of Crewe, has received the appointment of Additional Sanitary Inspector to the County Borough of Reading, at a commencing salary of £100 per annum.

Mr. S. G. Moore, of Liverpool, has been appointed Medical Officer of Health for Huddersfield, at a salary of £400 per annum, in succession to Dr. Annis, who will shortly commence his duties as Medical Officer of Health for Greenwich.

Mr. William Ethelbert Boughey, Clerk to the Medical Officer of Health for the Borough of Crewe, has received the appointment of Clerk in the Borough Treasurer's Department of the West Ham Borough, at a commencing salary of £100 per annum.

Mr. David J. Reid, C.E., Inverness, has been asked by the Thurso Town Council to report as to the best methods to be adopted, and as to the probable cost, of providing an augmented water supply and an adequate drainage scheme for the burgh, which is gradually growing in importance.

FORTHCOMING MEETINGS.

JUNE.

Friday 28th and Saturday 29th.—The Sanitary Institute—Examination in Practical Sanitary Science, Practical Hygiene for Teachers, and for Inspectors of Nuisances, Bradford.

Saturday 29th. — Architectural Association — Visit to Colney Chapel Convent, St. Albans.

JULY.

Thursday 4th.—Annual Meeting and Conference of the Urban District Councils Association at the Westminster Palace Hotel.

Saturday 6th.—Opening of the New baths at Wandsworth.

OBITUARY.

MR. JAMES JEMSON.

We regret to announce the death, under exceedingly painful circumstances, of Mr. James Jemson, Surveyor and Inspector of Nuisances to the Preesall Urban District Council. The deceased gentleman, who was 51 years of age, was a native of the Fylde, and went to reside in Fleetwood about five years ago. Previous to that he lived in the Over Wyre district. On the creation of the Preesall Urban District Council, Mr. Jemson was appointed Surveyor and Inspector of Nuisances under the Council, and he was only reappointed to the office a few weeks ago. For some time he has suffered from sleeplessness, a most distressful complaint, and had been in the habit of taking sleeping draughts. On the evening of the 16th inst. he went to Mr. Gornall's, chemist, Fleetwood, and obtained a draught similar to what he had been accustomed to taking, and then went home to bed. About two o'clock on Sunday morning he got up and went to Dr. Robinson for another draught, and the doctor gave him a bottle containing four doses. Mr. Jemson then returned home, and apparently took all the medicine at once and went to bed. Directly afterwards he commenced to cough and sneeze violently, and although a doctor was sent for and arrived within a few minutes, he died before the doctor's arrival. Deceased leaves a widow and three children, with whom the deepest sympathy is felt.

LAW CASES.

The Pollution of Rivers.

IMPORTANT APPEAL CASE.

An important point under the Rivers Pollution Prevention Act came up on the 22nd inst., in the King's Bench Division, before Mr. Justice Ridley and Mr. Justice Bigham, sitting as a Divisional Court. The case was that of the West Riding of Yorkshire Rivers Board *v.* the Scarr End Mill Company, and the appeal was from Judge Cadman, of the Dewsbury County-court. Mr. C. F. Lowenthal was for the appellants, and Mr. C. A. Russell, K.C., and Mr. Ellison for the respondents.

Mr. Lowenthal, in opening the case, said the appeal raised a short but important point in the construction of the Rivers Pollution Prevention Act, 1870. Under Section 4, it was made an offence for a manufacturer to cause polluting liquids to flow into a river, and under Section 10 a County-court judge might by a summary order restrain such action, disobedience being visited with a penalty of £50 per day. This was a highly penal statute, and, having regard to that fact, provisions had been inserted in the Act in the interests of an alleged offender. One of these provisions set out that no such proceedings should be taken without the consent of the Local Government Board, and it was also provided that in giving or refusing consent, the Local Government Board should have regard to the industrial interests involved, and to the circumstances and requirements of the locality. Therefore the Local Government Board were not to give their consent if they thought the pollution could not be stopped without unduly interfering with the industrial interests affected.

Mr. Justice Bigham: What is the point?

Mr. Lowenthal said the point was this. Under Section 13 of the Act no proceedings could be taken unless two months' notice of the intention to take proceedings had been given, and the appellants contended that it must be such a notice that, when it was given, the Rivers Board must be in a position to take proceedings. If when they gave the notice, and it expired, they were not in a position to take proceedings, not having obtained the consent of the Local Government Board, then the notice was bad, because the whole object of the notice was defeated.

Mr. Justice Bigham: What is the object of the notice?

Mr. Lowenthal: To enable the alleged offender to take steps to abate the nuisance, and prevent the necessity of proceedings.

Mr. Justice Bigham: Why did this notice not enable him to do so?

Mr. Lowenthal: Because when he got it he knew no consent had been obtained from the Local Government Board.

Mr. Justice Bigham: How does that matter? Why did that prevent him taking steps to abate the nuisance?

Mr. Lowenthal: It did not prevent him; but the question is whether your Lordships think that burden should be imposed on him, when it might be that when the Local Government Board are applied to for their consent they may refuse it.

Mr. Justice Bigham: The object of the notice is to enable the alleged offender to act upon it.

Mr. Lowenthal: But ought such a person to be compelled to act on a notice which may turn out ineffective?

Mr. Justice Bigham: If that is a question I am prepared to answer it at once—Yes. (Laughter.)

Mr. Lowenthal said that would defeat the provision which was inserted in the Act for the benefit of the alleged offender.

Mr. Justice Ridley did not think so. The offender was entitled to two months' notice, and was also entitled for it to be shown that the Local Government Board had given consent to the proceedings. If they had not given their consent up to the time of the notice, then perhaps the offender would get six months' notice.

Mr. Lowenthal said in that case there would be no effective notice at all.

Mr. Justice Ridley: The Act says nothing about effective.

Mr. Lowenthal urged that the respondents could have no intention of taking proceedings till they knew if they were in a position to do so, and if the Local Government Board refused consent they would not be in that position at all.

Mr. Justice Ridley: No, but it is a notice that they intend to take proceedings.

Mr. Lowenthal said that construction would mean that when a man got a notice he must act on it, though the expense he went to might be thrown away.

Mr. Justice Bigham: He need not act upon it. He may think he is quite safe, and that the Local Government Board won't give consent, or he may think the matter is so doubtful that he had better alter his methods of business.

Mr. Lowenthal said the Act also provided that any person against whom proceedings were intended to be taken should have an opportunity afforded him of appearing before the Local Government Board and being heard against such proceedings being taken. That carried the argument further. If notice could be given before the consent of the Local Government Board was obtained, then immediately the consent was obtained proceedings might be taken at once, and that would deprive the alleged offender of an opportunity of showing cause before the Local Authority.

Mr. Justice Ridley said he did not think there was anything in the point. He thought the decision of the County-court Judge was quite right on the point, and therefore the appeal must be dismissed with costs.

Mr. Justice Bigham agreed, and the case was dismissed.

"In future the two great illuminators will be called—one the 'Sun,' and the other, to ear-mark it from its competitor, the 'Kitson.'"—***From "Punch," May 27th, 1901.***

A REVOLUTION IN STREET LIGHTING.

THE KITSON

Incandescent Petroleum Light

IS THE

CHEAPEST & MOST BRILLIANT SYSTEM OF STREET LIGHTING

THAT HAS YET BEEN PRODUCED.

It can be seen on Portland Place, lighting the street from the Langham Hotel to Park Crescent.

It AVOIDS the NUISANCE OF TEARING UP THE STREETS.

A Committee of the Aberdeen Town Council, in a recent report, made the following statement:—

"We may at once say that no comparison can be made between the Kitson Light and ordinary, or Incandescent, Ga Lighting, as these are completely put into the shade by the Petroleum Light, and, comparing it with Electric Lighting it is very much superior both as to brilliancy and cost."

Before expending enormous sums in Electric Lighting, it would be worth while to investigate this System.

FOR PARTICULARS APPLY TO

THE KITSON LIGHTING AND HEATING SYNDICATE, LIMITED,

1, Victoria Embankment, Blackfriars, London, E.C.

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 83, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2243.—SANITARY INSPECTORSHIP IN INDIA.—"Jack" writes:—"In THE SANITARY RECORD for June 13th there appeared an article on Sanitary Inspectors in Bombay. Would you kindly let me know when and where examinations for these posts are held for them? I hold the certificates of Sanitary Inspector and of Inspector of Nuisances; would they be equivalent?"

Answer.—We regret to say we can supply no further information than that contained in the paragraph in question. Our correspondent should write to the Health Officer, Bombay.

2244. — FACTORY INSPECTORSHIPS: QUALIFICATIONS FOR.—"W. O. T." writes:—"In your issue of May 16th, query 2195, you refer in your answer to queries in back numbers of THE SANITARY RECORD with respect to examinations for Factory Inspectors. The copies referred to are, however, it is now found, out of print. Could you please repeat the information given in the answers referred to?"

Answer.—We reprint the answer referred to by our correspondent on page 559.

2245.—BURGH POLICE (SCOTLAND) ACT, 1892: SUBSTITUTION OF WATER-CLOSETS.—"J. M. C." writes:—"My Local Authority has passed a resolution that all proprietors of dwellings within the royal burgh where ashpits and privies exist, whether they are a nuisance or not, must remove them and introduce water-closets; see Section 246 of the Burgh Police (Scotland) Act, 1892. I argued that (1) they must be a nuisance under Section 16, Sub-section 2, of the Public Health (Scotland) Act, 1897, or (2) their construction must be defective, and certified by the Medical Officer of Health to be prejudicial to health under Section 255 of the Burgh Police (Scotland) Act, 1892, and (3) that Section 246 of the Burgh Police (Scotland) Act, 1892, was for the purpose of compelling proprietors of property to provide sanitary conveniences where none existed. I also stated that each case must be dealt with as found. I was, however, overruled by the clerk. Will you kindly give me your opinion?"

Answer.—We are of opinion that the contentions of the querist cannot be supported. The Local Authority are enabled, under Section 246 of the Burgh Police (Scotland) Act, 1892, to require the owner of every house into which water has been introduced to provide, wherever practicable, a sufficient water-closet. The powers conferred by the section named are comprehensive, and differ from similar provisions in the Public Health (Scotland) Act, 1897, and the Public Health (England) Act, 1875, relating to the provision of water-closets.

2246.—SEWAGE FROM HOUSES OUTSIDE DISTRICT.—"Inquirer" writes:—"A builds a house a short distance outside the district of an Urban Sanitary Authority, and requests such Authority to allow him to connect his house drains to their main sewers. This request is refused for various reasons, but chiefly on account of the Local Authority having contracted with an adjoining landlord to receive the whole of their sewage — not exceeding a certain quantity — for a certain sum per annum. If a certain stated quantity is exceeded, the Local Authority are then bound to pay the landlord an extra sum per year. A has now given notice to the Local Authority that, under Sec. 22 of the Act of 1875, he intends to connect his drainage to the main sewer. Assuming that under ordinary circumstances he has the right to do so, can the Local Authority refuse their consent under the circumstances as stated above, or can you refer me to any decision given in the Law Courts, or a similar case arising under the same section? The matter is an important one, as many plots of land are laid out for building purposes just outside the district, and there are several villages within a short distance, the property owners in which might be disposed to avail themselves of the sewers in a similar manner, especially if sewage disposal works, which are already in contemplation, should be carried out."

Answer.—The owner A is entitled, under Section 22 of the Act of 1875, to connect his drains to the sewer of the adjoining Authority, but only on such terms and conditions as may be agreed upon between him and the Authority of such adjacent district, or, as in the case of dispute, may be settled at the option of the owner by a court of summary jurisdiction, or by arbitration in manner provided by Sec. 181 of the Act. For cases decided under the section see notes in Lumley's "Public Health" to Secs. 22 and 28. The Council should impose such conditions, as they consider necessary, and by agreement under seal prohibit the connection of additional drains to that of the owner in question. Other owners could only drain to the sewer of the adjacent Local Authority by separate drains laid down from each house to the sewer of the adjacent district. The drainage of a number of houses into one common sewer, such sewer to be connected to the sewer of the adjacent Authority, would be a connection of the sewers of one Authority to that of another, and could only be done by agreement under Sec. 28 of the Act of 1875, and with the consent of the Local Government Board.

THE

FOOD INSPECTORS' HANDBOOK.

By FRANCIS VACHER,

Medical Officer of Health for the County of Cheshire.

The work has been carefully revised throughout, and a considerable number of additional pages appended, as well as several valuable illustrations, bringing it up to date in every respect. For the Sanitary Inspector and Inspector of Foods, the book in its present form will be found indispensable

THE SANITARY PUBLISHING COMPANY, LIMITED, 5, Fetter Lane, London, E.C.

THE OTHER SIDE OF THE QUESTION.

It is always well to look at both sides of a question; we therefore reprint from the *Liverpool Daily Post* the views of a medical man, which are opposed to those held by the majority of our readers. We invite correspondence on this important subject.

"ADULTERATION" OR PRESERVATION OF FOODS.

Life is, in these later days, made increasingly terrible by the work of the scientist and analyst, who discover in almost everything we eat, drink, wear, or breathe, something or other that is dangerous to health or life. We have ceased to wonder how our forefathers managed to exist (and thrive) on the myriads of germs they lived amongst, and the number of poisons they introduced into their systems by means of food and drink and air. They lasted a good deal longer, we must suppose, because they were wondrously tough, or on the principle that some people cannot be killed. But, though we owe a debt of gratitude to the workers who have exposed the numerous means by which foods and other articles of commerce are debased by inferior substances to the profit of the tradesman and the hurt of the purchaser and user, we are, I think, in some danger of making a natural desire for self-preservation degenerate into a craze and end in panic and foolish excess. There is all the difference in the world between taking care that we are not imposed upon by the substitution of sand for sugar or that of margarine for butter, and running amok at everything that can be safely utilised to ensure that foods shall reach the consumer and the consumer's stomach free from commencing decomposition. The addition to foods of preservatives is permitted by Act of Parliament, provided these are not added to an extent that can be considered excessive when the food is consumed in normal quantities.

I believe the Devonshire cream industry has been destroyed, as far as Liverpool is concerned, by the recent prosecutions for "adulteration" of the preparation with boracic acid. Here it is absurd to speak of the addition of a harmless antiseptic in small quantities as an "adulteration." Under the conditions of society at the present day, with enormous multitudes dependent on a constant food supply, and requiring this in convenient and varied forms, we shall have to face the problem of providing this, and providing it in a safe and reliable condition. This, I suggest, is impossible without the addition of preservatives, and the addition of preservatives should be recognised as necessary by Parliament, which should also state, after proper inquiry into the scientific aspects of the subject, what preservatives may be used, and in what proportions.

It is contended that antiseptics are not necessary; that foods can be put up in a sterile condition, as far as danger of germ infection is concerned, and the presence of decomposition. Allowing this, we are only protected as far as the consumer, not as far as the consumer's stomach. Your bottle of fruit wine, or condensed milk, or beef essence, or cream, is sterile and good when it is opened, but is it consumed at once? Rarely; for the thrifty housewife uses what she wants at the moment, and corks up the remainder, with the decomposing germ included, for future use. If you fine the manufacturer for adding preservatives to foods, you should look up the Health Authorities for preventing him making the wholesome addition, and permitting the unwary consumer to take foods which are in the early or later stages of decomposition, and which may be extremely dangerous to health, though the process of decomposition is not advanced sufficiently to be recognised by the usual domestic tests of smell and taste. In the meantime we are in danger of stretching the letter of the law to the bewilderment and confusion of her Majesty's lieges, who really don't "know where they are" in the midst of scientific alarms and Health Authorities' excursions. Take the Devonshire cream question. Milk we absorb in large quantities; it is old in a day, it is consumed as a matter of convenience and habit offhand, and it would be a fraud if foods understood to be, and bought as, fresh, and taken in these large quantities, were "preserved" by the addition of antiseptics, though these were harmless in small doses and when not taken in any excess, as they would be in a staple article of diet. But this does not apply to articles of commerce like cream, which is consumed in small quantities, and certainly in the case of Devonshire cream, not constantly, or, *e.g.*, products like margarine, known to be manufactured and necessarily preserved; or fruit syrup and non-alcoholic beverages which, however sterile to germ life when prepared and sent out, cannot long remain so when once opened. These require the addition of preservatives, and such as are commonly used in this connection are only deleterious when viewed from the standpoint of a vigorous scientific imagination, or if taken in such quantities that the preserved substance itself would prove harmful in. If we are to forbid these, we should forbid altogether the use of alcohol, which is much more certainly harmful and poisonous in excess than the preservatives used in foods. It is essential, therefore, to distinguish between foods bought as fresh, staple articles of diet, and those known to be manufactured and of necessity preserved. The question is one rather for the practising physician than the pathologist. The pathologist, grubbing in his laboratory, cannot be expected to have that practical familiarity with drugs and their effects on the human organism possessed by the physician, who is using them daily and hourly, and estimating their effect on the economy. We are not concerned with the pathologist's material—*e.g.*, rabbits and cats—as much as with that of the physician—human beings. I want to know if a drug is going to harm me, and, if so, what are the limits of safe consumption of it. I know that everything is poisonous if we take enough of it; and I know to my bitter cost, as many of us do, that there is no drug or poison so dreadful at times as decomposed foods, or that we suffer acutely or fatally, maybe from that which we cannot distinguish beforehand as becoming putrid. There is a scientific cant in these days, devised by the pathological ogre in his den, and followed too enthusiastically by those urgent for the public welfare. We must not, by avoiding the Scylla of adulteration, run into the Charybdis of decomposed foodstuffs. Let us know by due inquiry into all the grounds by competent and representative men—physicians and pathologists—what preservatives may safely be used. Let us find out the limits of safety; and let the blind prosecution of industries that are in themselves useful and convenient be conducted, not so much to assert a too rigorous theory as to promote the comfort and health of the community, understood in its widest sense.

HOW TINNED FOOD BECOMES DANGEROUS TO HEALTH.

Preserving food in tins is said to have been invented some ninety years ago. It is not such a perfect method of keeping food as is cold storage, but it is applicable under conditions where cold storage is practically impossible. On an exploring expedition, or for a military campaign, or under any circumstances where lightness of transport is an important consideration, the weight of a refrigerating machine effectively prohibits its use. It is very important, however, that great care should be exercised in every detail of the process of preparing tinned food, for if by any carelessness any mistake is made, the contents, instead of being wholesome food,

are often highly poisonous, and have frequently caused death. The *British Food Journal* says that there are two ways in which tinned food becomes dangerous to health. The first is by the growth of organisms, or, in other words, by the food becoming putrid, and the second by the dissolving of the metal of the tin or of the solder by the acid juices of the food. The prevention of the putrefaction can be absolutely ensured, but the risk of metallic poisoning can never be entirely done away with. The essential condition for the prevention of putrefaction is that the contents of the tins must remain at the temperature of boiling water for some twenty minutes; then, before the temperature is allowed to sink however slightly, the tins must be hermetically sealed in a thorough and efficient manner. If this process is done properly, there is no chance of the food becoming unsound unless the tin is damaged in such a way as to allow air to enter.

As regards the action of the juices upon the metals of which the tin is composed, one of the best precautions which can be taken is to only use solder which has been specially made for the purpose, and which has by long experience been proved not to be acted on by the food intended to be preserved, and to carefully test each boiling of the substance to see that the juice is not acid.

When a tin is purchased it should be examined externally before use. If the ends of the tin bulge outwards instead of being somewhat sucked in, the article should be rejected, for the tin is "blown;" the gases generated by the decomposition of the food have collected, and are exerting pressure on the tin. The dishonest manufacturer and dealer knows this sign of decomposition, and when the effect is noticed they prick the ends, and after allowing the gases to escape they re-seal the tin. Such tins are called "pricked tins," and the contents are often very dangerous to health. Such pricked tins usually have two dabs of solder on the end of the tin in place of the ordinary one. If this "pricking" be done cleverly, it is difficult to detect by outside inspection, and the odour and appearance of the food should always be very carefully noted when a tin is first opened. Any taint of decomposition, however slight, should be sufficient to condemn tinned food.

The only safeguard which anyone not a chemist can take to prevent being poisoned by any dissolved metals is to taste a little of the article, and carefully note if there is a metallic after-taste. If there is the sample should be rejected. All tinned food should be entirely removed from a tin and put into glass or earthenware vessels as soon as the tin is opened. If the contents are allowed to remain even for an hour or two in the tin, and exposed to the atmosphere, there is a great chance of the tin being partly dissolved, and consequently of a case of metallic poisoning occurring.

FISH UNFIT FOR FOOD.

DURING last month the officers of the Fishmongers' Company condemned as unfit for human food 61 tons 8 cwt. 2 qr. of fish at Billingsgate Market, representing 1 ton in about 209 tons, and 1 ton 4 cwt. at Shadwell, representing 1 ton in about 196 tons. The weight of fish delivered during December at or near Billingsgate Market was 12,869 tons, of which 10,845 tons arrived by land and 2024 tons were delivered by water; and at Shadwell the total delivery, 236 tons, was by land. Among the fish condemned were bream, catfish, cockles (6 tons 3 cwt.), cod (2 tons 4 cwt.), dorees, eels (18 cwt.), gurnets, haddocks (10 tons 12 cwt.), herrings (15 cwt.), ling, lobsters, mackerel, mussels (2 tons 16 cwt.), oysters (2 tons 8 cwt.), periwinkles (18 cwt.), plaice (9 cwt.), salmon, shrimps (3 tons 4 cwt.), skate (5 tons 10 cwt.), smelts (16 cwt.), soles, sprats (12 tons 19 cwt.), whelks (7 tons 5 cwt.), and whiting (3 tons 18 cwt.).

BOGUS MARMALADE.

SCOTLAND is discussing a question of great interest to eaters of marmalade. Mr. Thomas Jamieson, Public Analyst of Aberdeen, on examining twelve samples, found that while eleven were genuine, nearly one-half of the twelfth consisted of apples, and the person who sold this mixture contended that he had a perfect right to describe it as marmalade. He quoted the dictionary in support of his contention, and declared that he was perfectly entitled to use any bitter fruit in the manufacture of marmalade.

It seems that the term marmalade originated in Portugal. In that country marmalade was generally made from oranges, but sometimes quinces were used. Extending this view certain dictionaries define marmalade as being made from any kind of sour fruit.

Mr. Jamieson declined to accept the meaning given "by compilers of words" as representing the modern acceptation of the term, and Sir James Low, the head of a great Dundee firm of preserve manufacturers, on being interviewed, said that he had never heard of anything but bitter oranges and pure refined sugar being used in the manufacture of marmalade. If the public got anything else they were being certainly misled.

It appears that at present there is to be no prosecution, but the question is one of some importance to lovers of marmalade.

HOW BELGIUM DEALS WITH THE MARGARINE QUESTION.

A NEW law concerning margarine has just come into force in Belgium. The enactments are as follows:—

The term "butter" is reserved for fat obtained from milk or cream by churning, with or without the addition of ferments, colouring matters, or salts. Other alimentary fats resembling butter in their external characters, such as appearance, consistency, colour, odour, taste, are termed margarine.

Mixtures of butter and margarine for sale are prohibited. Margarine for sale may not contain more than 10 per cent. of fat derived from milk. It must be mixed with substances which, while being inoffensive and incapable of altering its organoleptic characters, will facilitate its distinction from butter. Particulars of these substances will be given later in a royal decree.

Produce destined for direct export is exempted from these provisions if declared prior to manufacture.

Margarine must be delivered from a manufactory or wholesale dealer in vessels bearing the word "Margarine" on every face, in letters at least $\frac{4}{5}$in. high, with the name and address of the firm.

Butter and margarine may not be sold on the same premises, and butter merchants or producers may not keep margarine even for their personal consumption on premises where butter is sold.

All shops where margarine is sold, as well as vehicles serving for peddling margarine, must bear the words "Sale of margarine" in distinct type at least 8in. high, and clear of all inscriptions. In market places margarine may only be sold at spots specifically indicated by the communal authority, and at least 25 yards from any butter-stall.

All vessels or wrappers in which margarine is sold must have the word "Margarine" in letters distinctly visible to the public, at least $\frac{4}{5}$in. high and clear of all other matters, as well as the name and address of the seller. If sold in blocks, these must be cubical in shape and marked in a similar manner.

Abnormal butter, *i.e.*, butter of which the characteristics differ from those of most pure butter, without exhibiting clearly adulteration or serious alteration, may

not be sold. A royal decree will specify the physical and chemical indications by which these characters may be recognised.

UNSATISFACTORY METHODS OF FOOD INSPECTION.

"In England it is safer to poison a man than to damage his trade," is the alarming statement made by Mr. W. Stanley Shaw in a communication on adulterated foods.

"This was proved the other day," he continues, "when an intelligent British jury awarded a firm of food manufacturers heavy damages against a morning paper which had published a paragraph concerning their productions. I believe it to be no exaggeration to say that half the people in London are, in some form or other, using unwholesome food. The sale of adulterated milk, diseased meat, bad beer, and very doubtful tinned or potted foods, flourishes like the green bay tree. Nor is it to be wondered at. Look at the difficulties that lie in the way of any ordinary ratepayer who is the victim of this state of things, and who wishes to take steps to protect himself! It is easier for a tradesman to poison a ratepayer, than for a ratepayer to stop the evil practices of a tradesman.

"This is an unsatisfactory state of things. Food adulteration should be punished more severely than it is, and the sale of unsound and diseased foods should be punishable by imprisonment. Nor should the retailer be made to bear the brunt. The wholesale merchant and the manufacturer should be made equally liable.

"As regards Inspectors, how can one man or two men combine the duties of Inspectors of Nuisances, Dairies Slaughter-houses, Petroleum, &c., and attend to four or five other duties as well for a district with a population of 200,000 or 300,000 people? It becomes a farce! What is wanted is a properly-qualified, properly-paid staff of men to thoroughly watch the interests of ratepayers who can individually spare neither the time nor the expense to do it for themselves."

Sugar by Electricity.—A new process of sugar refining is said to have been invented by a French firm. This consists in using electricity and manganate of lime in the clarification of the juice. Zinc plates are inserted in a series of tanks containing the liquid with which manganate of lime has been mixed. A current of electricity is then passed through the tanks. The new process is said to have the merit of cheapness, and by its adoption a considerable reduction in the price of sugar is promised.

CASES IN COURT.

[Records of Police-court proceedings for insertion in the "Food and Health" Supplement should reach us not later than the 10th of the month. Generally speaking, they should be as brief as possible, but where any important point of law is involved a fairly full report is permissible.—Ed. S. R.]

Water in Butter.

An appeal was recently argued before the Preston Quarter Session, the decision in which is of importance to provision merchants, farmers, and dairymen throughout the British Isles. The question at issue was the limit of water that should be allowed to remain in butter. The appeal had been suspended for some considerable time, because it had been expected that some commission would be appointed by the Board of Agriculture for fixing the standard of water, but an intimation had been received that no such fixing of the standard was likely to take place at present.

The appellants were the Peace and Safety Industrial Society, Limited, of Rawtenstall, who had been convicted by the Rossendale justices of having sold, to the prejudice of the purchaser, a pound of butter not of the nature, substance, and quality demanded by the purchaser, inasmuch as it contained 19·30 per cent. of water, contrary to Sec. 6 of the Food and Drugs Act, 1875. As the question affected the whole of the Irish salt butter trade, which exports to the value of nearly three millions sterling annually, a large number of eminent analysts, butter manufacturers, and merchants of considerable experience in home and foreign butter-making were called to speak as to the process employed in the Irish homesteads in the manufacture of Irish salt butter. It was pointed out that it was impossible to make Irish keeping butter to come within the maximum of 15 to 16 per cent. of water which is being established by the public analysts of the country, and that its manufacture necessitated the employment of brine, as opposed to dry salt, which the respondents held (though it was denied on behalf of the witnesses for the appellants) would give the effect required.

The appeal was allowed and the conviction quashed, the Bench being of opinion that the purchaser, having demanded Irish butter, got what, according to the ordinary use of the term, he might reasonably expect to get.

Both the appellants and the respondents agreed on the great desirability of some authoritative standard or standards being fixed. One suggestion was that there should be two standards, one for the creamery butter and one for the more heavily-salted butter known as Irish. Having regard to the magnitude of the interests

Over Five Hundred Hospitals

IS LIQUID LIFE.

and kindred public institutions, including all the most important in the United Kingdom, are regular users of Bovril. Such a practical public endorsement is conclusive evidence of the absolute purity of Bovril, and of its great value as a *nourishing* stimulant in convalescence.

involved to producers and consumers alike in the trade of butter imported from Ireland, and to the fact that there were two distinct classes of butter imported, and that it was desirable to prevent as far as possible confusion between them, it was the unanimous opinion of the Court that the question of fixing a presumptive standard or standards merited the early attention of the Board of Agriculture.

Diseased Meat in Edinburgh.

At a special sitting of the Edinburgh Police-court, held in the Sheriff-court Buildings, Sheriff Orphoot had before him two cases under the Public Health Act. The first case was that in which John Wyllie, cow dealer, residing at Fishbeck, Lockerbie, was charged with being the owner of four quarters of diseased beef intended for human food, which were conveyed to the Edinburgh slaughter-house, Fountainbridge, on December 3rd last. Accused pleaded not guilty.

John Riddock said the meat was dark in colour, and appeared to be that of an animal slaughtered while in a highly fevered condition. It had been taken to the Central Meat Market, but was refused admission. Witness admitted in cross-examination that the meat might be affected in a two days' transit.

Mr. James M'Phail, Veterinary Inspector, corroborated.

Dr. Williamson said he found the meat was dark in colour and soft in consistence. It appeared to him to have been the carcase of an animal in a feverish condition. He did not think there would be any appreciable difference in the meat by a two days' transit.

For the defence, Dr. Mitchell Watson, veterinary surgeon, Kirkcudbright, was examined. His evidence went to show that when he saw the carcase it had no symptoms of disease, and the meat was firmly set. The evidence of respondent was to the same effect.

The case was at the close of the evidence continued, in order that another witness, who was a veterinary surgeon, and unable to be present, might be heard.

The second case implicated Harry Q. Mitchell, farmer, residing in Newbiggin, Burntisland, Fife. He was charged with sending a live cow to the sale yard of Oliver and Son, in Valleyfield-street, Edinburgh, on December 11th last, which was diseased and unsound for human food.

Accused pleaded guilty, but on his behalf it was stated that when examined the cow was thin, but gave no cause for the suspicion that it was suffering from tuberculosis. He, however, did not take the proper precautions, but had no idea of the animal's condition.

The Sheriff said he thought the decisions given in that Court would have prevented the sending of diseased animals into market. But for the Inspectors discovering the condition of the cow it would have been used. He therefore would inflict a penalty of £10 and expenses.

Unsound Meat at Aberdeen.

In Aberdeen Police-court an important prosecution was brought against James Milne, senior partner of the firm of Messrs. Alexander Milne and Sons, preserved provision manufacturer. It was alleged that accused, as a partner of the firm, had in his possession for sale or in preparation for sale 1382 lb. of meat, all of which was unfit for human consumption. A plea of not guilty was tendered. Accused was defended by Mr. G. M. Aitken, Solicitor.

Kenneth Cameron, Sanitary Inspector, stated that he visited the works of the Messrs. Milne on December 21st, and examined several pieces of meat, forming one whole carcase, and nearly the whole of two other carcases, and the part of a fourth carcase. The sixteen pieces he seized were either tubercular or the meat was soft and flabby. All the meat seized showed unmistakeable signs of being unfit for human food.

Dr. Matthew Hay, who had accompanied the Sanitary Inspector on his visit, corroborated, and stated that the unfavourable symptoms must have been more apparent to the killer than to Mr. Cameron and himself, because measures had been taken evidently for the purpose of concealing these symptoms.

Matthew Donald, Assistant Sanitary Inspector, deponed as to the lining membrane being stripped off, obviously with the intention of obscuring the presence of the disease. Witness denied that two months ago Mr. Milne requested him to permit nothing but good meat to be transferred from the market to his premises.

George Wood, cattle dealer, was the first witness for the defence. In answer to Mr. Aitken, witness stated that he supplied the best of meat to the Messrs. Milne. The supplies to that firm amounted in value to between £400 and £500. Alexander Scott was in his employment, and killed all his animals. The carcases were delivered at the Messrs. Milne's business premises. He always purchased healthy animals, and paid a fair price. The four animals whose carcases were condemned were killed on the December 20th. Messrs. Milne paid a full price for good meat at the rate of 4¾d. to 5d. per lb., and taking very large quantities. In reply to the Fiscal, witness admitted having been three times convicted for having meat unfit for human food.

Alexander Milne, senior partner of Messrs. Milne and

"than in Cocoa not so prepared."

Sons, said he had special charge of the meat department. They had two practical butchers in their employment for the purpose of seeing that no bad meat came through their hands. He understood that the meat had passed the Inspector at the market, and that it was absolutely sound. His men had not had time to inspect the carcases, but would have done so before the meat was used.

Alexander Scott, who killed the animals in question, said he knew the meat was diseased. He did not inform either Mr. Wood or Messrs. Milne. He thought it best for his master's interests to take up the meat to Messrs. Milne. He gave instructions that the carcases should be carried in so that the disease would not be seen when the meat was put on the scale.

In reply to the FISCAL, witness said he took out the glands and the lining membrane to hide the tubercles. He was only carrying out his instructions.

The FISCAL: You knew you were doing what was wrong. If your employer asked you to go and steal something for him, would you do it?—Well, I don't suppose I would. This is a different matter.

The FISCAL: Then it comes to this, that it does not matter how bad your instructions are, you will carry them out because it is part of your employment?—Quite so.

The FISCAL: Did you ever take such instructions before?—No; this was the first time.

The FISCAL and Mr. AITKEN having addressed the Bench, the magistrates retired.

On returning, Bailie HENDERSON said they had very carefully considered this case. They were of opinion that Mr. Milne's method of inspection was not what it ought to be, and with reasonable care the condition of the meat could have been found out. A fine of £10, with 24s. 6d. of expenses, was imposed, the alternative being twenty-one days' imprisonment.

Arsenic in Beer.

THE Sanitary Committee of the Manchester Corporation last week took action against twelve beer retailers, who it was alleged had sold beer which contained arsenic. The summonses were taken out under the Food and Drugs Act, and defendants were charged with supplying beer not of the nature, quality, and substance demanded by the purchaser. There was a crowded attendance at the City Police-court. Mr. T. F. BYRNE appeared on behalf of the prosecution, and Mr. FLETCHER MOULTON, Q.C., M.P., and Mr. C. P. MCKEAND represented the defendants. M. J. HISLOP watched the proceedings on behalf of the Manchester and Salford Beer and Wine Trade Association.

The first case taken was that against Elizabeth Goulder, beer retailer, of Hulme. Mr. BYRNE, in opening the case against the defendant, said the Inspector called at Mrs. Goulder's licensed premises on November 21st and saw the defendant's niece, who, for the time being, had the management of the house. He asked for a quart of fourpenny beer. Defendant's niece fetched it from the cellar. A portion was sent to the Public Analyst, Mr. Estcourt, for analysis. Mr. Estcourt certified that it contained arsenious acid to the extent of one-eighth of a grain per gallon. The prosecutor contended that the presence of any quantity whatever of arsenic in beer made it not beer of the nature, quality, and substance demanded, but made it beer mixed with a drug, and a dangerous drug, too, which had no business to be there.

Mr. Estcourt, in reply to Mr. FLETCHER MOULTON, said he had received warnings as to the presence of

arsenic in beer. Witness did not suggest that any blame could attach to the defendant for the presence of the arsenic in the beer. It was not specially difficult to detect the presence of arsenic in beer. The quantity of arsenic referred to in the charge, viz., one-eighth of a grain per gallon, roughly speaking, represented a proportion of one part in half a million. In his private practice as an analytical chemist he had never heard hitherto of an analyst looking for the presence of arsenic in beer.

Dr. James Niven, Medical Officer of Health, stated that arsenic ought not to be taken except under the most careful medical supervision. People differed in susceptibility, and seven-eighths of a grain per week would be injurious when taken for some time, and would produce disease such as had been observed in the hospitals. He had been in practice twenty years, and during that time it had never occurred to him to suspect arsenic in beer, though he had examined beer. He would not commit himself to the assertion that no one had up to that time ever suspected or known of the presence of arsenic in beer in minute quantities. In his own experience he had found that the great majority of beers subjected to analysis contained glucose obtained from one particular firm. The effect of small percentages of arsenic in beer would be deleterious on account of the quantity consumed. In further explanation he added that in a population of 40,000 people who drank beer an individual might be found here and there who would be susceptible to injury from the practice of consuming the beer.

Mr. Fletcher Moulton, in addressing the Court, remarked that the summons in this case ought not to have been taken out under Sec. 6, but under Sec. 3, which dealt with what he might call contamination. That was to say, that there was added to the article asked for something which was a hurtful contamination. Sec. 6, he contended, dealt entirely with adulteration; that was to say, where an article sold was not the article asked for, but an article which had been so manipulated that the purchaser did not merely get a contaminated or uncontaminated but an entirely different article. Commenting on the case generally, he said the world had learned a terrible lesson with regard to the possibility of arsenic being present in food, and the source of danger to the public was now being destroyed for ever. He admitted the gravity of arsenic being found in beer in such quantities, and said that after this the avenues by which such contamination could creep in would be effectively closed, and in future they would hear no more of it.

Mr. Byrne, in replying to Mr. Moulton's argument, said that an offence under Sections 3 and 4 of the Act was one matter, and a much more serious matter for the retailer than an offence under Section 6. To sell an article knowing it to be impregnated with a dangerous or injurious substance was a very serious offence, meriting a serious punishment. Section 6, however, applied expressly to the retailer, and to no one else.

The decision in this and other cases was adjourned for three weeks.

GLUTEN FLOUR AND BREAD.

By Martin Priest, A.I.C., F.C.S., and William Partridge.

Several samples of gluten flour have recently come under our notice in which starch was present to the extent of over 50 per cent. Recollecting the warnings put forward about two years ago by Dr. Fielden in the *Pharmaceutical Journal*, and also an article in the *British Medical Journal* on "The Chemistry of Diabetic Foods," it is surprising to find still upon the market a large number of such so-called gluten flours.

As this is a subject which vitally concerns the health of diabetics, and yet receives so little attention from members of the medical profession who have the dieting of diabetic persons, we do not wonder that many bakers and manufacturers of diabetic foods take advantage of this inactivity and place upon the market with impunity forms of diabetic food which contain so large a percentage of starch as to be fatal to the successful treatment of the disease.

Patients, too, ignorant of this fact, consume as much as they think fit of these fictitious gluten breads, taking it for granted that starch and sugar are both absent from the preparations, often doing themselves more harm than if they took normal quantities of ordinary bread.

There appear to be great differences of opinion as to the proper definition and composition of gluten bread. Those concerned with its manufacture generally state that it is composed solely of gluten except for a little fat which is left in by some methods of preparation. On the other hand, many medical and chemical authorities on the subject think that bread composed entirely of gluten may often be advantageously replaced by a preparation retaining one-fifth or one-sixth of the starch of the flour incorporated with it.

Pure gluten bread frequently fails to satisfy the craving which diabetic persons possess for starchy matters which is greatly increased by total prohibition of starch, and preparations made solely from gluten are in addition hard, brittle, and usually have an unpleasant doughy taste. This being so, in cases of mild diabetes, where patients respond to treatment, gluten breads containing a small percentage of starch might be found valuable.

We see that certain manufacturers advertise their bread as retaining a certain percentage of the original starch, and we think that this practice might be carried a step further, and different grades of bread containing varying amounts of starch should be prepared, each loaf to possess a label indicating the percentage of starch, so that medical men may alter the composition of the diet in accordance with the requirements of the case. But the amount of the bread should most certainly be regulated, as harm is done if excessive amounts, containing even a small proportion of starch, be taken by the patient.

Not only gluten bread, but diabetic foods generally, need revision to a large degree, as very erroneous ideas as to the composition of the different foods are prevalent. Cownley (*Pharmaceutical Journal*, 1898, ii., page 327) points this out in a list of such so-called gluten articles, which he showed to contain very varying and in most cases large percentages of starch.

Where any doubt exists as to the composition of purchased bread, suitable bread may easily be prepared at the patient's home, which has the advantage of ensuring that the patient obtains it in a fresh condition. For its preparation Dr. Gordon Sharp (*Pharmaceutical Journal*, 1898, page 363) advises that the flour should be washed until nearly all the starch is removed, and then mixed with bran and made into a loaf. He also mentions that oatmeal washed for several hours, and then served with cream, will be found a valuable article of diet for diabetics. A suggestion for preparing diabetic milk will be found in *British Medical Journal*, 1898, ii., page 190, and a preparation of curds is described on page 932 of the same volume.

For the separation of gluten from flour several processes may be resorted to. A centrifugal method is mentioned in *Journal* Society Chemical Industry, 1900, page 918; but the simplest, and perhaps the most reliable, is the following:—A strong flour is made into a stiff dough with water only, and allowed to stand for nearly an hour, and then carefully kneaded in small portions at a time. The starch escapes in a milky solution, leaving the gluten behind as a soft sticky mass. When the washing water becomes clear it shows the absence of starch. If the gluten be washed in running water it will retain a little fat, but will be free from starch and sugar. The kneading under water is most conveniently done in muslin bags.

Gluten is also produced as a waste product in the manufacture of starch, but in this case the full value of the gluten is not always obtained. The "sour" process is an example of this, which is carried on in the following manner:—The grains having been coarsely ground, are moistened with water and allowed to stand for a few days until fermentation sets in, when more water is added, and the putrefactive fermentation continues for several weeks, until all the gluten is dissolved. The latter is then washed out of the starch. Obviously here, there is some loss of gluten at whose expense the fermentation goes on.

Another process, which is used chiefly in the case of rice and maize grains, is based upon obtaining the solution of the gluten in a 3 per cent. solution of caustic soda, the starch granules being insoluble. The gluten being afterwards precipitated by an acid. Gluten is generally baked in the form of small rolls or buns, which swell to an enormous extent during baking, and the section of such a loaf shows large empty cavities. The proportion of gluten in flours varies from 8 to 18 per cent., the average being about 12 per cent. To get a flour rich in gluten the soil should contain a sufficient but not excessive amount of nitrogen. A hard wheat (yielding a strong flour) contains more gluten than a soft wheat. Gluten constitutes a most valuable part of wheat flour, and is an extremely valuable foodstuff. As prepared by washing flour till free from starch, it is an adhesive, sticky, elastic, mass with a brownish or greyish tinge, but when freed from water it is translucent and colourless, and it is said that about 96 per cent. of such gluten is digestible.

Gluten is not a definite substance, but is composed chiefly of gliadin, glutenin, and soluble salts. Different authorities disagree as to the number of proteids contained in it; for example:—Ritthausen states that by extracting gluten with dilute alcohol he obtained three proteids gluten-fibrin, plant-gelatin, and mucedin; but Osborne and Vorhees (*American Chemical Journal* xv., No. 6) come to the conclusion that only one proteid soluble in dilute alcohol exists, viz., gliadin, and one proteid insoluble in dilute alcohol called glutenin.

Gliadin has appeared before the scientific world in different states of purity and under different names, as plant-gelatin, mucedin, mucin, and gluten fibrin. It was first called gliadin by Taddei on account of its resemblance to glue. It is soluble in dilute alcohol, but insoluble in absolute alcohol. It is slightly soluble in cold water, but the presence of salts greatly lessens this solubility. It is also soluble in very dilute acids and alkalies. In the hydrated condition gliadin is a soft, sticky substance. With cold water it acts as a binding material and makes the gluten tough and coherent.

Glutenin in the pure form is a greyish-white, non-sticky mass. On drying at 100 deg. it forms a slightly brownish horny material. It occurs in wheat grain to the extent of 4 to 4·5 per cent. It is insoluble in dilute alcohol, water, and saline solutions, but soluble in dilute acids and alkalies. It has appeared under the names of zymom, plant-fibrin, gluten-casein, and gluten-fibrin.

Gluten owes its solidity to the glutenin, which forms a nucleus to which the gliadin adheres, and thus prevents it being washed away. Gluten also contains a slight amount of mineral matter, chiefly soluble salts, which prevent the gliadin dissolving. The estimation of gluten in flour may be effected in several different ways, the simplest being to wash the starch away from the flour and weigh the residual gluten, but as the results obtained vary with the amount of washing, length of time of standing, &c., it is desirable that the flour should be mixed with a certain amount of water, allowed to stand for a definite time, and so forth. Variations of this process are given by Allen ("Commercial Organic Analysis," vol. iv., page 76) and by Wanklyn and Cooper ("Bread Analysis," page 43). In the latter method the authors make corrections for the ash (0·3 per cent. on the flour), and for the fat (1 per cent. on the flour.) Gluten may be estimated in flours, breads, biscuits, and other preparations by estimating the total nitrogen either by Kjeldahl's process or by a combustion of a small quantity of the substance with copper oxide and then multiplying the percentage of nitrogen by 6·33, which gives the percentage of gluten.

On the principle that vegetable substances generate ammonia when subjected to the action of a boiling solution of potash and potassium permanganate, Wanklyn estimates the gluten in flour by a modification of his well-known ammonia process in water analysis. L. Reed (*Journal* Chem. Soc., 1884, A, page 122, and *Chem. News* xl., page 63) describes a colorimetric method of estimating the gluten in flour based on the principle that nitric acid acts on albuminoids to produce a yellow nitro-compound. The flour is systematically treated with colourless nitric acid, and the colour produced is compared with that produced by a standard flour.

For the estimation of the starch, Fielden converts 2 grammes of the flour with 20 c.c. of sulphuric acid and 200 c.c. of water for three or four hours, neutralises the liquid with caustic soda, and estimates the sugar by Fehling's solution, and returns the result as percentages of sugar and starch together.

ARSENIC IN BEER AND FOOD.

"ARSENIC in Beer and Food" was the subject of a lecture by Mr. William Thomson, delivered before the Society of Arts. This poison, he said, was in very limited use in the arts and manufactures. It was mixed with lead in the manufacture of small shot, being necessary to produce perfect spheres. Arsenic was, therefore, one of the constituent parts of game, and a considerable dose of this poison was taken when a small shot was accidently swallowed by a person partaking of game. Fortunately, however, in this condition arsenic was not easily acted upon by the juices in the stomach. From 6000 to 10,000 tons of arsenic were annually used in Great Britain, principally in Devonshire, in making metal buttons, as when polished, it took a brilliant silvery lustre. Soot contained a large quantity of arsenic, coming presumably from the pyrites or brass-like pieces which were found in coal. One sample which he examined contained $1\frac{1}{2}$ grains to the pound, or $22\frac{1}{2}$ maximum medical doses. Arsenic must almost be regarded as having been a natural constituent of beer from the method of drying malt during the past century. Sprouting barley was dried in rooms which were heated by means of fires kept up with coke and anthracite coal. Arsenic was emitted from coke and coal fires even when there was no smoke. The danger consisted in the fact that it condensed upon the grains of malt. Out of 62 samples of malt which he had analysed, only seven were free from arsenic, the rest containing from $\frac{1}{200}$th to $\frac{1}{17}$th grain of arsenic trioxide to the pound. In the latter case it would represent nearly $\frac{1}{4}$th of a grain to each gallon of beer—a serious amount. Anthracite coal contained from $\frac{1}{100}$th to $\frac{1}{200}$th of a grain of arsenic per pound, while in coke there was from $\frac{1}{3}$rd to $\frac{1}{100}$th grain per pound. Of 220 samples of beer which he had analysed, twenty-one were free from arsenic, and the rest contained from $\frac{1}{200}$th to $\frac{1}{8}$th of a grain of arsenic trioxide per gallon. Taking the average of these samples, considerable quantities of beer would have to be drunk before even the minimum medical dose of arsenic would be swallowed. It might be suggested that minute quantities of the most powerful poisons, such as strychnine, acted as excellent tonics, but there was no record in which these poisons had been taken over a period of years as articles of daily consumption. Dealing with sulphuric acid, he said that immense quantities were made from Spanish copper pyrites, and as a result this acid usually contained as much as 0·2 to 0·4 per cent. of arsenic, and one sample of acid used in the manufacture of sugar contained 1·4 per cent.

Sir Lauder Brunton said he had had some personal experience of arsenic poisoning. His house had been newly done up, and he discovered arsenical poisoning symptoms in himself. He was assured that the wall paper was free from arsenic, but in his own case analysis showed that it was absolutely loaded with this deadly poison.

ANTISEPTICS IN FOODSTUFFS.

THE sentiment of physiological chemists is perceptibly changing of late with regard to the use of antiseptics in food, some authorities even going so far as to sanction their use to a limited extent. Many recent experiments in artificial digestion made by Chittenden, Leffmann, and others, on the toxic effects of formaldehyde and other antiseptics, which were considered almost in the light of poisons a few years ago, have tended to show that some of these antiseptics, far from being harmful, may be even helpful in certain of the digestive processes. Much interesting work is being done at the present time along this line. With such encouragement there is little wonder that the use of antiseptics is on the increase, though at present it is an open question how far their use should be allowed in food.

SOME OF THE PROPERTIES OF OYSTERS.

OYSTERS have for centuries been much esteemed by medical men as being very nutritious and easy of digestion, but both these properties are much diminished when not taken in their raw state. It may not be generally known that the fluid which surrounds the oyster bears a closer analogy to the gastric secretion than anything else in nature. In addition to the solvent properties of this fluid, it is not without its nutritive properties. We have of late devoted considerable attention both to the substance and the secretion emanating from it, and find that in a given weight of the latter and the same of the oyster, the fluid yields only 40 per cent. less of animal gluten or jelly than the fish; consequently all persons who are accustomed to eat oysters should be ever mindful that as little as possible of the juice should be lost. To effect this purpose they should always be opened in the bottom shell. When oysters are either stewed or scolloped the two properties, as before stated, are much diminished, consequently, ought not, by invalids in particular, to be taken except in their raw state.

ARSENICAL POISONING BY BEER.

Dr. Buchanan has issued his report to the Local Government Board on the recent epidemic of arsenical poisoning attributed to beer in the Midlands. It is of a preliminary and inconclusive character, in view of the appointment of the Royal Commission to inquire into the whole matter, and it does not encroach upon the field of inquiry of the Commission, which is of a wider and more strictly scientific character, to serve as a possible guide for legislation. The report, however, summarises concisely the leading features of the epidemic, and the conclusions arrived at as the result of the investigations. These have been largely anticipated by the report of the Manchester Committee of inquiry, as well as by the findings in the various coroners' inquiries in Manchester, which are now so much a matter of public knowledge that it is not necessary for us to traverse Dr. Buchanan's official report. The cause of the recent epidemic may now be held to have been satisfactorily established. It was due, as Mr. Long stated in the House of Commons, "to the substitute supplied by one manufacturing firm, into which this poisonous matter—arsenic—had got, owing to carelessness so extraordinary that it was difficult even now to realise how such a thing could have happened." With the discovery of the cause, the epidemic was at once arrested, though it cannot even yet be said to be at an end. The loss entailed on the brewers must have been enormous, for beer which was discovered to be arsenical was poured by hundreds of gallons into the sewers. All this loss, of course, comes back upon the Messrs. Bostock, of Liverpool. Not only are the claims against them by brewers, for the value of beer destroyed, enormous, but they have £100,000 worth of sugar on their premises, which is quite useless, as it is contaminated with arsenic. The result has been to force the unfortunate firm into liquidation. Meantime, Mr. Chaplin, Sir Cuthbert Quilter, and the advocates of the agricultural interest in Parliament are not content to await the report of the Royal Commission, but insist on legislative action being taken forthwith. Such haste must be deprecated. Panic legislation is never wise, and in this case there is no occasion for the panic that Mr. Chaplin's speech on the Address would indicate. Mr. Long had no difficulty in pointing out that, so far as the recent epidemic was concerned, the tracing of it to a single definite source, and its arrestment there, practically brought to an end any immediate danger, and it would be most unsafe and inexpedient to propose legislation without the solid foundation of scientific fact, which can alone be afforded by the report of the Royal Commission. But the anxiety of Mr. Chaplin and his friends, it is manifest, is not on account of the public health, which is Mr. Long's sole object, but to protect the barley grower.

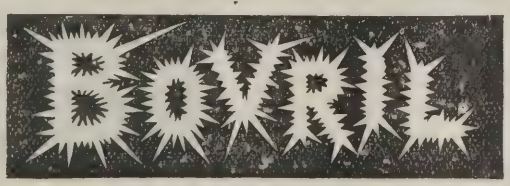
ALE AND BEER IN THE SIXTEENTH CENTURY.

The composition of ale and beer, says the *Lancet*, has always been of interest to members of the medical profession. Dr. Andrewe Boorde, who lived in the reign of Henry VIII., gives a full account of the composition of most of the beverages which were in use in his own time. He considered that water was not "holsome sole by it selfe for an Englysshemen" because it was "colde, slowe, and slacke of dygestyon." Ale, he said, for an Englishman was the natural drink. It was in his time made of malt and water fermented by yeast. It had, in his opinion, to be fresh and clear, not ropy or smoky. It appears to have been drunk very shortly after it was made, for he says that it ought not to be drunk under five days old, and that new ale was unwholesome for all men. He observed also that sour ale was good for no man, an observation which has been confirmed by subsequent experience. Contrary to the opinion of some modern brewers, he considered that barley malt made the best ale. He confessed, however, that in spite of its good qualities the beverage engendered gross humours, but he added that it made a man strong.

In his description of the composition of ale no reference is made to hops, and it appears that they were not used in the drink which he called ale, for he looked upon other ingredients, except those which he mentioned, as being adulterations. The composition of beer was different. It was made of malt, hops, and water, and was, he observed, the natural drink for a Dutchman. Of late days it had indeed been used in England, but unfortunately with detriment to many Englishmen, and it was especially harmful to those who suffered from colic, "for the drynke is a colde drynke," he observed. Yet, he said, it made a man fat—a point on which the observer could satisfy himself by examining the faces and other parts of the persons of Dutchmen. The beverage had, however, one good point, which was that if it were well served in good condition, and not new, it qualified the heat of the liver. Dr. Boorde was a great traveller, and amongst other things he especially noticed the condition of the food and the drink in all the places which he visited.

Of the ale of Cornwall he formed a very low estimate; it looked white and thick, "as if pygges had wrastled" in it, and he gives some unsavoury particulars as to the ill-effects of drinking this beverage into which, perhaps, it is hardly necessary to follow him. In Boorde's time it does not appear that Scotland was celebrated for good ale as a general rule. Although fish and flesh were to

Over Five Hundred Hospitals



IS LIQUID LIFE.

and kindred public institutions, including all the most important in the United Kingdom, are regular users of Bovril. Such a practical public endorsement is conclusive evidence of the absolute purity of Bovril, and of its great value as a *nourishing* stimulant in convalescence.

be had there in plenty, the ale, he says, was evil, with the sole exception of that brewed at Leith. Dr. Boorde was extremely severe in the punishments which he thought should be meted out to brewers of bad ale and to those who gave short measure. He gave it as his opinion that they ought to be placed in the Thames up to their chins and 3in. above, and suggested that when they came out they would have to shake their ears as a spaniel that verily came out of the water. Dr. Boorde devotes one chapter of his book to soups, stews, and other articles of diet which would now be classified under the general heading of invalid food. Amongst his recipes he recommended ale brews and caudles for weak men who could not eat solid meat. In many country districts these old-fashioned compositions are still used and sometimes perhaps with satisfactory results.

PERSONAL AND PUBLIC HEALTH.

THE third of a series of Health Lectures was recently delivered by Dr Andrew Wilson at Barrow. The lecturer pointed out that there are three essentials to life—first, food; second, water; third, air. Without food and water an ordinary human being would live a week; supply a man with water alone and he would last twenty, thirty, or even forty days. But without air we could live only a few minutes. We spend money and take a great deal of trouble to get food; our corporations spend enormous sums in order to supply the towns with water. What provision do we make for getting air, which is most necessary for life? He answered, no provision at all. It was nothing short of a disgrace that at the end of the nineteenth century we have no scientific system of ventilation at all generally adopted. Proceeding, Dr Wilson dealt with the nature of the breathing process as illustrated in low life and in higher animals, and then described the lung, its structure, its air cells, its blood supply, the relation of the lungs to the heart, the physiological trio—lungs, skin and kidneys; the work of getting rid of waste, and how the lungs play their part in this work, breathing and its mechanism. Coming to the air we breathe, its composition, its purities and impurities, the lecturer pointed out the absolute necessity, in the interests of public health, of a universal knowledge of the laws of health. And could he rule, he said he would instruct every child in the country before he or she left school—where he would keep them longer than some of them remained even at the present day—he would instruct every child in the laws of health; greater attention should be paid to the health of their bodies, and each and everyone should go through a course of physical exercises. Putting down his pointer with which he had been drawing attention to the lantern illustrations, Dr Wilson addressed the audience very earnestly upon the all-important subject of consumption, every case of which, he said most emphatically, is one of infection. As a precaution against consumption he urged the public to boil or sterilize the milk bought for consumption. He hoped to see the day when municipalities will sterilize the milk for us, but it would be far better to have an intelligent nation thinking these things out for themselves. Consumption did not begin with a cold, but a cold weakened the lungs, and so rendered them more susceptible to the microbe or germ of the disease; 20,000,000 of these germ were coughed up by a consumptive man in one day. Hence the necessity for great care. Consumption, he assured his hearers, could be prevented, and he urged them to do all in their power to enlighten themselves and others upon this most important subject. He proceeded to give a word of warning against tight-lacing amongst women, demonstrating on the screen the very manifest deformity caused by these attempts at a false ideal of beauty. In conclusion, the lecturer again dwelt upon the importance of pure air, and made an eloquent appeal to the people of Barrow to continue their interest in the Gilchrist lectures, in order that they might be followed by a continuation course.

HOW ARSENIC GETS INTO MALT AND HOPS.

MR. C. ESTCOURT, official Analyst for Manchester, has dealt with this matter in an interview with a representative of the *Daily Mail*:—

The explanation is simple, he said. When the malt has completed growing it is damp and moist. If it were allowed to remain in damp it would become mouldy and grow again. The desire of the maltster is to check that. The malt is, therefore, thrown on a kiln and subjected to heat from coke or steam coal, and it comes into absolute contact with the fumes of the fuel. It follows, therefore, that if the coal or coke contains arsenic the malt becomes impregnated with the poison. Of course the amount of arsenic in coal varies. If it were always to be found only in very small quantities there would be nothing to make a noise about; but I say the method of drying does not permit one to control the quantity. Again, the arsenic may increase according to the length of time the malt is heated.

How did I make this discovery? I knew that infinitesimal quantities of arsenic were produced by this

It contains all the goodness of the wheat, prepared in such a way as to be suitable for all, even those ailing and dyspeptic. Most Family Bakers supply it daily.

"the results distinctly indicate the advantage of
"VAN HOUTEN'S PROCESS of manufacture. Thus
"this Cocoa yields a maximum proportion of the
"valuable food constituents of the bean, and what
"is of more importance still, these are presented
"in a condition more easy of assimilation and digestion
"than in Cocoa not so prepared."

process of drying, but to my astonishment a brewer who had eliminated, as he supposed, all impure materials and brewed his beer from malt and hops and pure glucose, sent me a sample, and I found it contained a good deal of arsenic.

ADULTERATION OF FOOD AND DRINK IN MANCHESTER.

REPORT OF THE CITY ANALYST.

A REPORT of the Manchester public analyst, Mr. C. Estcourt, for the last quarter in the year 1900, upon the articles analysed by him under the Sale of Food and Drugs Acts and the Margarine Act was presented to the City Council last week. Mr. Estcourt makes the following observations on his work:—It will be observed that the percentage of adulteration of spirits is very high, and strangely uniform. This I ascertained in two cases was due to a defective instrument used by the publican in breaking up his spirits. The percentage of samples adulterated of milk is very low, and I am pleased to be able to state that no cases of fat abstraction were found this quarter. The adulteration of golden syrup by the addition of a large quantity of starch glucose appears to have ceased entirely. With respect to tea the public still suffer, from the fact that there is no standard laid down for mineral matter. Until this is done the addition of sand and other mineral matter cannot be certified as adulteration, as this extraneous matter is supposed to have got in during the process of collection or manipulation. The same remarks apply to ginger and many other natural products. Apart from the samples of beer contaminated with arsenic, the percentage of adulterated samples continues very low, being equal to only 3·4 per cent.

With regard to those beers contaminated with arsenic which contain one-tenth of a grain of arsenious acid per gallon and upwards, there can be no doubt from the investigations carried out that this quantity is largely due to the impure glucose used in the manufacture of beer. Although only one firm of glucose manufacturers has been publicly incriminated so far, it should not be forgotten that I have informed the health department of the Corporation that at least two other manufacturers have delivered glucose to brewers in Lancashire which contained arsenic in considerable quantity. It thus becomes imperative on brewers to examine every sample of glucose which is delivered into their breweries. Regarding the smaller quantities of arsenic found in beer—namely, from one-tenth to one-two-hundredth of a grain of arsenious acid per gallon—I am of opinion that this is probably due to the malt used. I have found malt on the market and in use by brewers which, if used in brewing without any glucose, would pollute the beer to the extent of one-tenth of a grain of arsenious acid per gallon. This information I have also conveyed to the health department. Nothing but a new method of drying malt, which will prevent the fumes of the fuel from coming in contact with the malt, will do away with the certainty of pollution with arsenical fumes. It will be seen that until a change is made in this respect a beer brewed from malt and hops alone will not necessarily be pure. Total number of samples analysed during the quarter, 432; number of samples adulterated, 52.

CHEESE AS A FOOD.

CHEESE is a very rich and valuable food likely to form a very large constituent in the future, and especially for the working man, to be very extensively used. There is a difference in stomachs in their ability to digest this article. The writer is able to make an entire meal of cheese with very little bread, and digest it more easily than rice or oatmeal; but in most stomachs it is less digestible, in some extremely so. Each person must learn for himself. It is a convenient form of animal food, and, when good, particularly agreeable. The varieties of cheese are numerous. Some imported cheeses, like two or three varieties from Germany, are abominable in smell and most unwholesome. Cheese was known to the ancients. Homer, Aristotle, and others mentioned it. It is mentioned in the Bible. There is a great difference in the composition of cheese, both in its water, fat, and nitrogenous matter. In general, however, it might be remarked that every variety contains a large amount of nitrogenous matter, and it is for this that it is especially useful as a food. Skim-milk cheese is especially rich in this constituent, but less rich in fat. Those who abstain from flesh food will find in cheese abundance of nitrogenous matter to take the place of that found in flesh.

ADULTERATION OF COFFEE.

COFFEE offers a ready field to the skilled manipulator, who uses for his materials almost anything he can roast and grind, as peas, pea hulls, chicory, pilot bread, red slate, &c. A common adulterant is a mash of ground, roasted wheat or peas, moulded together with molasses and coloured with red ochre. In some cases it takes the form of a very clever counterfeit in point of appearance of the whole coffee beans. They contain no coffee whatever, and consist almost wholly of roasted wheat. They are moulded so neatly as to hardly be distinguishable in outward appearance from the genuine. Coffee substitutes are, as is well known, very common. Most of these contain cereals only, but one very well advertised brand, purporting to contain nothing but the entire wheat kernel roasted and ground, has also peas and about 30 per cent. of that "most noxious drug," coffee itself.

CASES IN COURT.

[RECORDS of Police-court proceedings for insertion in the "Food and Health" Supplement should reach us not later than the 10th of the month. Generally speaking, they should be as brief as possible, but where any important point of law is involved a fairly full report is permissible.—ED. S. R.]

Adulterated Coffee.

AT Hadleigh Petty Sessions, before Messrs. H. Newman (chairman), T. N. Scarfe, and G. T. Harrison, Alfred Christie, grocer, was summoned by Superintendent Peake, under the Food and Drugs Act, 1875, charged with selling as pure coffee a mixture of coffee and chicory.

Mr. C. E. SALMON prosecuted.

Defendant was fined £1 and £1 17s. costs, and paid the money.

Raid on Margarine Sellers.

TWENTY summonses under the Margarine Act were heard at Southwark Police-court against ten defendants for selling as butter mixtures of butter and margarine, and for neglecting to wrap the articles in papers labelled "Margarine."

All but one of the defendants were convicted, and penalties ranged from £20 and costs to £5 and costs.

Unsound Meat at Glasgow.

A CATTLE-DEALER named John Gilmour, 43, Fullarton-street, Kilmarnock, was fined £5 by Bailie Robertson at the Glasgow Central Police-court for having exposed for sale in the cattle market a cow which was diseased and unsound.

The case was a very lengthy one, lasting for several hours.

THE CHEMISTRY OF COOKING.

No woman can be said to be thoroughly proficient as a professor of housewifery until she understands something of the chemical elements of food, and the purpose they serve when taken into the system. The use of chemistry in cooking is to teach how to supplement one kind of food for another which contains certain essential elements lacking in the first. The human body has been likened to a machine, and like any other machine, it is constantly wearing out. Every movement and every breath is breaking down cells and tissues, and this waste must be repaired to keep the body in normal working condition. Food taken into the system has two offices to perform, the repairing of bodily waste and the supplying of fuel to keep the bodily heat up to 98 degrees. Foods may be divided into three classes, nitrogenous, carbonaceous, and those in which both are united. Nitrogenous food repairs bodily waste and builds up muscle and tissue, and carbonaceous food supplies fat, heat and energy to the body.

Of late, too, especial attention has been given to brain and nerve food, and it has come to be understood that if we would send forth from our homes into the world healthy, brainy men and women, well equipped physically and mentally for the battle of life, we must see to it that nerve and brain, bone and muscle, flesh and blood are all fed and nourished and built up, each with its own element of food. And thus the necessity of a balanced ration for the family is plainly seen. When a knowledge of the needs of the body is supplemented by intelligent cooking, a wholesome, strengthening and nourishing meal is the result. Cooking, too, loses its old sense of common drudgery when considered as a scientific process, and a cook who understands food values and the chemistry of every-day cookery has a perfect right to consider herself a scientist.

Of nitrogenous foods the richest is found in the albumen of eggs, lean meat, the curd of milk, peas, beans, oats, and whole wheat flour, and many vegetables of which cabbage and onions rank first. Carbonaceous foods are in two classes, the fats and the carbohydrates, both containing the hydrogen and oxygen. The fats include the fat of meat, cream, butter, vegetable oils and grains. Carbohydrates include starch and sugar, sugar being cane sugar, honey and the sugar of fruits. The starches include the starchy vegetables, as potatoes, and cereals, as rice, corn, wheat and oats. Milk is an almost perfect food. It strengthens the whole body. The cream gives us fat; the whey contains the salts and phosphates that strengthen the brain, bones and digestive organs, and the curd is the muscle-making, energy-producing substance. Eggs are rich in nitrogen and also sulphur for the brain and nerves. But as a brain food, fruit heads the list, containing as it does the salts and acids which are exceedingly wholesome, and which aid so materially in the digestion and assimilation of other foods, fish, eggs, oysters, lobsters, game and cheese.

From this it will be seen that the food that would best sustain and nourish a labourer in the open air would not be the best diet for a brain worker. A dinner of boiled salt pork and cabbage and whole wheat bread is nearly perfect for an outdoor labourer, as the cabbage is rich in nitrogen and the pork in carbon. Beans next to meat contain the most nitrogen, and are excellent food for labourers, and next comes oats, wheat and barley. In cold weather the system requires more carbonaceous food, and in summer fruit, creams and vegetable salads should appear on the bill of fare. And from this it will be seen that a knowledge of food elements and the needs of the human body is quite necessary in order to provide the different members of the family with a balanced ration of food best suited to their needs.

Every housewife should supplement her collection of cook books with a good work on the chemistry of food, and should make its contents a special study. Scientific stockmen have come to consider the balanced ration a necessity for the best development of animal life, and how much more so must it be for the best mental and physical developement of human beings.

THE FEEDING OF INFANTS.

The death-rate of infants from diseases incident to the alimentary canal is truly appalling, and since this condition depends largely upon dietary we conceive at a glance the prominence of the subject. If we in every instance could furnish the ideal food, we would meet the panacea to the prevention of these dread diseases. Observation, as well as experience, has proven that the welfare, the health, and the growth of the infant depend not so much on medicine as proper care and feeding. We believe that if a strict and proper diet sustained in every instance, infantile mortality would be reduced 90 per cent. If these opinions are true, our profession is alarmingly ignorant or negligent of its duty in the premises. We concede, however, that in many cases the physician is not responsible for these results. Often, and most often as for that, he has no knowledge of the condition of the infant or its mode of life until it is in the clutches of some dread disease. Then, when sent for, he must play the *rôle* of an instructor, a lecturer, and proceed to enlighten the mother, the aunt, the grandmother, of the little unfortunate—a most difficult task.

Concerning the infant's nourishment, let our ideal be nature's ideal—the *mother's milk*, and this our guide around which all other foods revolve in seeking perfection; remembering, however, that mother's milk is the ideal to the extent that we are furnished the healthy milk from healthy mothers.

Many mothers are not healthy, and even if they are they often give poor milk. These are points of interest, and require careful study, since the health, and welfare, and even the very existence of the little one depend upon them.

To improve conditions of mother and quality of her milk we look to tonics and regulation of her life and habits. If she be constipated, anæmic, or nervous, these impressions are transmitted to the infant, and he suffers the consequences. If constipation the fault, relieve by exercise, habit, and proper medicine; if nervous exhaustion, rely on nerve tonics and rest; if anæmia is of the kind that can be relieved do so; if permanent and of a serious constitutional character, withdraw the infant at once from the breast and depend entirely upon the "bottle."

With reference to the quality of milk the question naturally arises at this stage, What are the constituents and their proportions of good healthy mother's milk, and what the amount of such food required by the average infant that he may thrive best? Proper and careful analyses have shown that infants to do best should receive milk which contains fats, proteids, sugar, and salts in following proportions, respectively: 4, 1½, 7, and 2 per cent. These investigations may be sufficiently accurate to be remembered, and any great variation therefrom may be viewed with suspicion. While the quality remains practically constant, the quantity varies with age of infant. The average healthy child receives during the second and third week of life approximately twenty ounces of milk per diem; at twelve to sixteen weeks, one quart; and a continued increase with the age until at one year he consumes between forty and fifty ounces of milk every twenty-four hours. Regularity of

feeding, length of time at the breast, and amount fed at each nursing, are considerations well worth remembering.

The nursing children are not the ones however, about whom we are mostly concerned; if so, the solution of this problem would be comparatively nil. His more unfortunate brother—the one for whom nature has failed to provide—is he who demands our attention and profound consideration. This age of inherited weakness, depraved nature, and growing pathogenic tendencies, calls for wakefulness, watchfulness, and alertness on our part.

No branch or subdivision of medicine gives us more concern than artificial feeding. And here we might give our opinion concerning the employment of wet nurses. I have my serious doubts as to the propriety of ever relying upon this means of feeding. When we remember the class of individuals from whom we are to select, and when we remember how readily constitutional diseases are transmitted through the breast, and when our attention is further called to the fact that the expense of employing a wet nurse reaches far beyond the financial strength of most people, we think it wise to abandon this method altogether, and rely upon our skill to prepare properly other foods.

The best, and without doubt the most convenient, of the artificial foods is the cow's milk. It contains essentially the same ingredients as the mother's, but in different strength. To convert this into acceptable nourishment much preparation is required. We must select the healthiest cows fed on the best and purest food. Use rather the milk of a herd than that of a single animal. Other considerations are the age of the food, its cleanliness, and its strength. These are of paramount importance, since bacteria increases with age of milk, and since these pathological conditions depend directly upon these poisonous germs.

This matter is of more import in cities than in small villages and in rural districts. The milk here is often forty-eight to sixty-four hours old before being used. What, then, is the best method of preparing this milk for long-continued use?

After the age of eight, ten, or twelve hours, it will not bear being fed plain. It is claimed that heating milk to the point of 167 deg. Fah., known as pasteurisation, sufficiently sterilises it to destroy typhoid, diphtheria, tubercular and scarlet-fever germs, and at the same time does not alter the taste or the digestible quality of the food. If these investigations are true, and we accept them as such, this is better than subjecting it to a higher temperature. This we believe to be the best means of preserving milk for short periods of time. While for travelling long distances, sea voyages, &c., in way of convenience, condensed milk is best. The preparations of this we are all more or less familiar with. It consists of heating fresh cow's milk to a temperature of 212 deg. Fah., for a stated time, then evaporating *in vacuo* at a low temperature and adding cane sugar. This is conveniently kept in tin cans. When fed we add ten or twelve parts of sterilised water to one part of milk. This reduces the percentage of casein until it is easily assimilated by the most delicate stomach.

In studying the subject of cow's milk for infant feeding, we should examine it from every point of view, even to the selection of the dairyman and his herd. Call this party's attention to his responsibility in the premises. The more nearly immaculate he can present himself, his herd and their compartments, the more fortunate for all concerned. The physician can do much to encourage him in this respect. If practicable, organise a board of health. Have the milk examined as to cleanliness, strength, and age, and refuse to tender your approval or endorsement until these requirements have been scrupulously complied with.

WINE ADULTERATION IN PARIS.

An extraordinary story of wholesale adulteration of wine in Paris is told by a contemporary. The beverage in question, which has, it appears, been selling like wildfire for the past few years at a low price, is described as "natural wine" and "vin des vendages." That it hardly deserves these attractive appellations has been shown by the analyses of some 2000 specimens made at the Municipal Laboratory of Chemistry. Not a single pint of the so-called wine was found to be unadulterated. The foundation of the beverage consists of "vin piqué" or "vin de pressurage," officially stated to be unfit for consumption. This was mixed with some real and rather strong wine, which provided the flavour. To the concoction was then added 40 or 50 per cent. of water. But the "wine" required still further manipulation before it could be retailed to unsuspecting consumers. A harsh acid taste, which remained from the original "vin piqué," had to be counteracted chemically, and this was achieved by the addition of potash, chalk, and baryta, among other substances. Even this, however, was not the final stage in the adulteration. Owing to the considerable proportion of water the beverage still required "strengthening." With this end in view various chemical substances were further added, such as tannin, tartaric acid, citric acid, and in some instances phosphoric and even sulphurous acid. The concluding statement of the Municipal Laboratory report, that the mixture in question "constitutes a beverage injurious to the health," is certainly incontrovertible. It is said that the manufacturer of this fearful concoction has made some £10,000 a year profits out of his "wine" selling business.

DANGER IN CHEESE.

A good deal is written upon the sterilisation of milk, but are butter and cheese innocuous? It would appear that the latter is, at all events, not wholly free from dangerous properties, as a serious case of cheese poisoning recently occurred in America.

A portion of the cheese which gave rise to the poisoning was sent for examination to the State Laboratory of Hygiene at Ann Arbor. The bacteriological examination revealed the presence of the colon bacillus in the virulent form.

The colon bacillus is a germ which is always present in the alimentary canal of warm-blooded animals. It is present in great numbers in the excreta of cows, horses, and other domestic animals. These germs are always found in milk because of the contamination of the milk by barnyard and stable filth, which is rarely separable from the conditions in which milk is ordinarily produced.

The fact that this bacillus is present in cheese is an important one that ought to be brought to the notice of the public everywhere. It is also important to know that this germ is capable of giving rise to symptoms closely resembling typhoid fever. Cholera morbus is, perhaps, chiefly due to the action of this germ in a virulent form. It may also cause peritonitis, abscess of the liver, pneumonia, and a variety of other grave infections. The tubercle bacillus has also been found in cheese several weeks old.

Those who insist upon eating cheese should take the precaution to cook it thoroughly before eating. It is for this reason that some people who are unable to eat raw cheese find themselves able to eat toasted cheese without difficulty. Toasting the cheese does not, however, increase its digestibility, but rather the reverse. Its beneficial effect, if any, is from the

destruction of the virulent microbes which are present, and which are capable of giving rise to symptoms even more distressing than those of ordinary indigestion. The best method of dealing with cheese is to give it to the pigs, as it is nothing more or less than decayed milk, and is fit only for a scavenger diet.

REGULATIONS FOR MILK AND CREAM.

The Departmental Committee appointed by the Board of Agriculture to inquire into, and to report upon, the desirability of making regulations with regard to the sale of milk and cream have just published a very interesting document containing their recommendations. Despite the opinion expressed by many that the problem of controlling the milk trade was one which well-nigh defied perfect solution, yet the overwhelming body of evidence, says the *Lancet*, is in favour of the view that the setting up of some statutory limits for milk is necessary. Unless it be held that the Food and Drugs Acts are as regards the sale of milk unnecessary—a view actually taken by not a few—it is difficult to escape from the conclusion that some limits should be fixed in order to make analysis a criterion as to the quality of the milk. It has been proposed that seasonal limits might be adopted in order that no injustice should be done, for it is true that the quality of normal milk varies at different seasons of the year. The adoption, however, of a set of minimal limits which should be applicable at all times and under all conditions to milk produced for consumption, is the course which has commended itself to the committee. Ultimately, after a careful survey of the evidence, the committee are disposed to conclude that the milk produced for sale in this country contains on an average from 12·5 to 12·8 per cent. of solids, comprising from 3·7 to 4 per cent. of fat. Any milk, therefore, the committee consider, in which the total solids are less than 12 per cent. should be further inquired into, and if it should be then found that the amount of butter-fat is less than 3·25 per cent. a presumption would be raised that it had been mixed with separated milk or water, or that some of its original fat had been abstracted; if the solids, not fat, are found to be lower than 8·5 per cent., a presumption that it had been mixed with water would arise.

In regard to cream the committee are of opinion that the weight of evidence was not favourable to the establishment of official limits of fat; nor does it appear that any substantial difficulty arises in selling cream in different qualities, at corresponding prices to meet the requirements of the public. It is very properly considered, however, that steps should be taken to prevent the artificial thickening of cream by the addition of gelatine or other substances. The recommendations of the committee also relate to the composition of separated milk and condensed milk, in regard to the quality of which similar recommendations as to limits are laid down. The report is signed by all the members of the committee except one, who, being unable to give his assent to the principal recommendations, embodies his own conclusions in a separate report. Mr. Barham in this report is in favour of the adoption of a seasonal standard. He takes 3 per cent. of fat as fairly representing, with 11·75 per cent. total solids, the milk during the months from July to February inclusive and the same amount of total solids with 2·75 per cent. of fat for the months from March to June inclusive. In any case he regards the milk as deficient in its normal constituents when the total solids are less than 11·75 per cent. and the non-fatty solids than 8·5 per cent. Mr. Farmer signs the report subject to a reservation. He also agrees to seasonal limits and objects to the suggested limit of 3·25 per cent. of fat for the whole year. We feel sure that it will be ultimately shown that legislation can only be satisfactorily applied towards upholding the supply of milk of good quality by the adoption of one limit for all seasons of the year. Moreover, since it was announced some months ago that the limit adopted at the Government laboratory was 3 per cent. of fat, the quality of the London milk supply has very materially improved, as shown by the latest analytical returns.

ALCOHOLISM AS A FACTOR IN INSANITY.

In a journal devoted to questions of health, it is impossible to overlook the health of the mind as well as of the body, for the two are intimately related. Indeed, the best opinion now holds mental disease to be simply bodily disease, resulting as directly from physical disorders of the brain as diseases of the body do from disorders of the various organs affected. And it is distressing to know that this class of disease has been very much on the increase in recent years. Dr. Clouston, physician to the Royal Edinburgh Asylum for the Insane, in his annual report brings out several features in connection with this subject with most painful emphasis. The past year has been a record one for admissions, the number being 38 over the average of the past five years. Among the causes to which this increase is to be attributed he has no hesitation in ascribing the first place to alcoholism, which, in its turn, is due to the exceptional prosperity of the country, with brisk trade and high wages during the last few years. Last year 115 cases, or about a fourth of the whole admissions to the Edinburgh Asylum, were alcoholic cases. Dr. Clouston points out that his alcoholic lunatics rose from an average of 15½ per cent. in the years 1874-1888, to 21½ per cent. in 1889-1898, to 22½ per cent. in 1899,

and to 24½ per cent. in 1900. He would also add 49 general paralytics to the list as due to the same cause. There had never been so much general paralysis before, and he put a large part of it down to a bad use of prosperity. This increase in alcoholic insanity occurs chiefly in the large towns, but it is noteworthy that the largest increase in general insanity does not come from city populations, as might have been expected with their artificial modes of life away from nature, their stress of circumstances, and their drinking. On the contrary, to use Dr. Clouston's graphic words, "The greatest increase by far had really taken place in the northern and highland counties, where mankind still lived in the quiet of green fields, or in sight of the smiling ocean. The increase in those rural and seashore counties had been 80 per cent., while the rest of Scotland had only gone up 42 per cent." In Edinburgh itself there has even been a decrease in proportion to the population. From these Blue-book figures Dr. Clouston draws two contrasting pictures. On the one hand, we have the Highland crofting families, where most of the young and energetic members had gone south to push their way in the world, leaving behind only the old and less energetic minded, with no mental vigour to stay the onset of disease; and on the other, the vigorous city worker, making more money in good times than his educations and social requirements could utilise for his legitmate enjoyments, tempted by the dangerous mental ideals which alcohol could create for him, and so undermining his physical and mental constitution.

FOOD AND DRUG INSPECTION IN MASSACHUSETTS.

Some interesting details on Food and Drug Inspection are embodied in the 31st annual report of the Massachusetts State Board of Health. From this it appears that cheese is subject less to adulteration in Massachusetts than any other of the principal articles of food. Of thirty-four examples examined, no evidence of adulteration was found; but the real reason for this is the lack of a legal standard of quality. Several samples of skimmed milk cheese were found. Massachusetts has no law fixing the standard of fat in cheese, and in the absence of such a law skimmed milk cheese can be sold with impunity. Five of the Western States have laws fixing the standard of fat from 20 to 35 per cent. Tabulated statistics show that the laws of 1883 to prevent adulteration have brought about a marked improvement. This is especially true of butter, condensed milk, condiments, coffee, molasses, maple syrups and maple sugar, honey, confectionery, and canned goods. The percentage of adulteration in these articles is much lower than a few years ago; but in wheat flour, spirits, wine, beer, and cider, drugs, jellies, and jams, a good deal of adulteration exists.

While adulterated coffee is one of the most common forms of falsification found in the markets, adulterated tea is comparatively rare. At the beginning of operations under the Food Acts in 1883 the markets were still flooded with the cheap imitations of coffee which became so common soon after the civil war. They were mostly put up in packages containing one pound in each package, the mixture containing variable percentages of chicory, roasted peas, beans, wheat, rye and other cereals. They were usually sold at a much lower price than pure coffee. There is now a considerable demand for coffee substitutes, and many brands of roasted cereals find a ready sale and are mostly labelled honestly. At the present time the adulterations of coffee are chiefly those which consist of a mixture, the chief ingredients of which are usually pure coffee in the proportion of sixty to eighty per cent., the remainder consisting either of chicory or cereals or both, the whole being sold either in bulk or in packages of two to five pounds or more. These are usually labelled as blended or mixed coffee, or often as pure coffee, but quite as often they bear a misleading label, which, after considerable study, appears to indicate a mixture.

The general result of analyses of coffee shows a reduction from 33 to 18·7 per cent. of foreign substance. Several years ago an artificial coffee berry was invented, having a very close resemblance to the genuine roasted berry. It was undoubtedly believed by the manufacturers that this imitation could be used successfully by mixing it with roasted, unground coffee berries in certain proportions. The false berries, however, being made of roasted starch or of similar material, lacked the most important characteristic of genuine coffee, the taste or flavour. Hence as an adulteration they proved a failure, especially in States where food inspection is practised.

The examination of teas shows a remarkable freedom from adulteration, the whole number of samples collected being 976, with only 31 adulterated samples. The ratio of adulteration in the later period was greater than that of the first, but this fact has little significance, since the absolute numbers in each case were quite small.

Within the past few years adulteration has found in jellies and jams a fruitful field of operation. Not many years ago the principal constituents of such articles were chiefly fruit, sugar, and water; but the tendency to cheapen the product has led to the introduction of glucose instead of cane sugar, of cheaper instead of the more expensive fruits, and of aniline dyes to imitate the colour of genuine fruits.

It contains all the goodness of the wheat, prepared in such a way as to be suitable for all, even those ailing and dyspeptic. Most Family Bakers supply it daily.

"than in Cocoa not so prepared."

HOW MILK SPREADS DISEASE.

An outbreak of scarlet fever resulting from milk supplies is referred to in the annual report of Dr. Thurwell, Medical Officer of Health for the borough of Gravesend. He says:—"On February 26th and up to March 1st, a sharp exacerbation took place, in which almost all the houses infected were supplied by one dairy; this is outside our district—in the Strood rural. On February 28th I visited the dairy in company with the Sanitary Inspector and the Veterinary Surgeon, and took two samples of milk for bacteriological analysis, and the report of these from University College was submitted to the Committee and to the Local Government Board. One of the cows was considered doubtful as to some pimples on the udders, but was afterwards declared to be satisfactory. The place was well kept, and clean, provided with ample cleansing arrangements. It was said that no one at the dairy had been ill with anything like scarlatina. On March 1st I received information that one of the men who delivered milk had been ill and away from work for four days. I went to the dairy and examined him, and found him desquamating freely on the neck, arms, hands, and feet; some of the skin affected was quite characteristic. He was at once suspended from work and sent to his room, and later removed to the sanatorium. The cow stalls were disinfected; the cows' udders were cleansed with disinfectant, and later it was considered advisable to have the whole place limewashed. Eighty-six cases were reported about this time in three weeks. It was quite apparent that where this milk carrier had been on his round was worse affected. Up to the end of June we had a good many cases, but after that time there was a general subsidence. There have been 208 notifications during the year, and 118 of these were between five and fifteen, 40 were between one and five, 39 between fifteen and twenty-five, 9 were over twenty-five, and 2 under one year. The inspection, cleansing, and isolation, and later the disinfection, has entailed a vast amount of work. The epidemic has been of a very mild character—only two deaths have taken place. Owing a great deal to the mildness of the disease some cases have not been recognised before desquamation. A woman was convicted before the magistrates for continuing to go about the town as usual, although she was aware that she was suffering from scarlatina; she had taken no precaution whatever against spreading the disease. With the means now at our disposal it is not probable that we shall have to deal with so many cases in the future."

ARSENIC IN FOOD AND DRINK.

"Owing to the prevalence of arsenical poisoning in certain parts of the country," says Dr. Alfred Hill, Medical Officer of Health and Analyst to the city of Birmingham, "I tested thirty-two samples of ale and beer, and twelve samples of brewing materials for the presence of arsenic. In one of the samples of beer a very slight trace was discovered—about one-hundredth part of a grain per gallon—while in two samples of glucose a larger quantity was present. The firms from which these three samples were obtained immediately recalled all the beer which was likely to be contaminated, and ceased using the impure glucose. Eighteen samples of golden syrup and table syrup, seventeen of jam and marmalade, and eight of sugar confectionery, were also examined, but presented no signs of the pre-

sence of arsenic. From inquiries made at the General Hospital, Workhouse Infirmary, and Skin and Urinary Hospital, I learn that the cases of alcoholic neuritis treated at these institutions in the last six months of the year were fewer than those which occurred in the first six months. I find also that the deaths recorded in the city from the same complaints were rather fewer in the second half of the year than they had been in the first half, numbering five against seven. It appears probable, therefore, that the cases of neuritis were not the result of arsenical poisoning, but of other causes, and that Birmingham has, fortunately, suffered but little, if at all, from the presence of arsenic in beer or other articles of diet."

THE INSPECTION AND DISPOSAL OF TUBERCULOUS MEAT.

ACCORDING to the *Aberdeen Journal*, the butchers of that city complain that the application of the law in regard to the destruction of condemned meat is more rigorous than in other towns. Inquiries have, however, elicited the fact that such is not the case. It may be mentioned that the practice in Aberdeen is based on the following recommendation contained in a circular issued by the Local Government Board in October, 1899 :—

Principles to be Observed by Meat Inspectors in the Inspection of Tuberculous Carcases of Cattle.

We are of opinion that the following principles should be observed in the inspection of tuberculous carcases of cattle :—

The Entire Carcase and all the Organs may be Seized :—

(*a*) When there is miliary tuberculosis of both lungs.

(*b*) When tuberculous lesions are present on the pleura and peritoneum.

(*c*) When tuberculous lesions are present in the muscular system, or in the lymphatic glands, embedded in or between the muscles.

(*d*) When tuberculous lesions exist in any part of an emaciated carcase.

The Carcase, if otherwise Healthy, shall not be Condemned, but every Part of it containing Tuberculous Lesions shall be Seized :—

(*a*) When the lesions are confined to the lungs and the thoracic lymphatic glands.

(*b*) When the lesions are confined to the liver.

(*c*) When the lesions are confined to the pharyngeal lymphatic glands.

(*d*) When the lesions are confined to any combination of the foregoing, but are collectively small in extent.

In respect of foreign dead meat, seizure shall ensue in every case where the pleura have been "stripped."

Mr. Kenneth Cameron, Chief Sanitary Inspector for the city, points out that the inspection in Aberdeen is carried out strictly in accordance with the above rules, which, though permissive in their operation, are nevertheless the authorised views of the chief administrative body in the country, and founded on the report of the Royal Commission on Tuberculosis. He states that if other Authorities or officials fail to carry out these rules, that cannot alter what he believes to be right and what he feels to be necessary in order to protect the public and give effect to the law. If the law is less rigorously enforced elsewhere, the inference is that the Authorities in these places are not fully carrying out their duty. He asserts there is not a single case where the action in Aberdeen has been in excess of the above regulations, and these he regards as the minimum required to protect the public health. Whole carcases are not confiscated unless they come under the first category.

There were 300 separate seizures last year, but it would be a mistake to suppose that they were all made by the sanitary officials pouncing in upon dishonest traders and seizing carcases sought to be surreptitiously disposed of as human food. In many cases notice is given to the sanitary officials by the owners that meat appears to be unsound, and the officials are asked to come and see the suspected lots, with the result that they are generally condemned. It is often the butcher or cattle dealer who is most surprised when a slaughtered animal shows signs of tuberculosis, and in the case of the more responsible members of the trade the discovery is notified to the Authorities. Of the 300 seizures last year the unsound lots in 296 cases were destroyed, "with the consent of the owner." In only four cases was a magistrate's warrant required to secure the destruction of the material seized.

CASES IN COURT.

Adulteration and Obstruction.

AT the Manchester County Police-court, before Mr. J. M. YATES, K.C. (stipendiary), and other magistrates, John Nevin was summoned under the Food and Drugs Act on three charges—for adulterating coffee, refusing to sell coffee, and obstructing Inspector Parker whilst in the execution of his duty.

On the 21st of January the Inspector visited defendant's shop in Swinton Hall-road, and asked for four ounces of coffee. Defendant refused to sell, but afterwards he said he would sell him only one ounce. The Inspector put his bag on the counter, and was going to divide the article when the defendant took it off and put it on the floor. It was afterwards analysed and found to contain 40 per cent. of chicory.

Defendant was fined 5s. and costs in the first case, and he was ordered to pay the costs in the other two cases.

Foreign Fats in Butter.

AT the same court, Patrick Kelly, of 47, Cross-street, Gorton, was fined 20s. and costs for selling butter containing 80 per cent. of foreign fats and 12 per cent. of water.

A fine of 40s. and costs was imposed on Joseph A. Railston, 202, Moss-lane East, Moss Side, for selling margarine for butter. When the Inspector visited the defendant's shop he asked the price of the butter, and was told 1s. 3d. and 1s. a lb. He then asked for 1 lb., and paid 1s. for it, and inquired what kind it was, and defendant's son replied, "Irish." The defendant afterwards came in the shop himself, and said it was margarine, but the transaction had been completed. Defendant was fined 40s. and costs.

Glucose in Jam.

A PROSECUTION for the sale of marmalade adulterated with glucose took place at Worthing, and a fine of £1 and costs was imposed upon a retail grocer named Smith.

Mr. de FONBLANQUE, solicitor, of London, appeared for Messrs. Crosse and Blackwell, the manufacturers, who accepted the entire responsibility. They distinctly pleaded not guilty, as they claimed they were perfectly entitled to do what they had done. He differed from the ruling given by the Bench a week ago, submitting that jam (and in the word he included marmalade) was fruit cooked in a medium which had the quality of preserving it, provided that the medium was wholesome. There was nothing to prevent the manufacturer from seeking to meet the tastes of his customers. It was intimated that the appeal would be taken upon this rather than upon the preceding cases.

MILK AND MEAT FROM TUBERCULOUS ANIMALS.

INFECTION THROUGH THE DIGESTIVE TRACT.

The danger from the use of milk and meat from tuberculous animals is sufficient to justify the enactment of efficient laws to protect the public against the danger, and the careful execution of such laws; nevertheless, those persons who assume that the use of tuberculous food products is the prime factor in the causation of human tuberculosis are deeply in error. In the State of Maine, in the seven years 1892-98, only 266 deaths were recorded as due to abdominal or mesenteric tuberculosis, while from tuberculosis of the lungs 8429 persons died.

It is not here contended that every fatal tubercular infection which has its starting point in the intestinal tract presents a symptom-complex which eventuates in a death returned as from abdominal tuberculosis. Dr. Woodhead * says:—"I have seen in case after case in children, and in animals fed on tuberculous material, the lungs markedly affected, but in a large proportion of these cases it has been possible to trace the course of invasion back from a caseous or old calcareous mesenteric gland through the chain of retro-peritoneal glands up, through the diaphragm to the posterior mediastinal and bronchial glands, and so on to the lung. I have not seen this in a few cases only, but in dozens of children, in a few adults, and in many animals."

Tuberculosis of the intestinal tract and of the mesenteric glands is much more frequent among children than among adults, but even among children, these forms of tuberculosis, due principally to the use of milk from a tuberculous source, are much less prevalent than is primary tuberculosis of the bronchial glands and of the lungs. Biedert, quoting the results of the post-mortem examination of the bodies of 1346 cases of tuberculosis states that, in 79·6 per cent. of them there was a localisation of the disease in the lungs; in 78 per cent., in the bronchial glands; in 31·6 per cent., in the intestines; in 40 per cent., in the mesenteric glands.

In a paper by Dr. L. E. Holt, of New York, giving the results of the autopsies on 119 tuberculous children, tuberculous lesions were found in the lungs in 99 per cent., in the bronchial lymph nodes in 96 per cent., in the intestines in 37 per cent., and in the mesenteric lymph nodes in 35 per cent. of the subjects. He says:—"The source of primary infection of the alimentary tract may be either the milk of a tuberculous nurse or tuberculous cow, or tuberculous meat. All of these I believe to be extremely rare. Their importance in the etiology of tuberculosis in infancy I think has been very greatly exaggerated. In the series of autopsies above given there was not one in which a careful study of the lesions made it at all probable that the primary lesions were of the stomach or intestines, and in 63 per cent. of these cases the intestines were not affected at all. In the cases where the stomach and intestines were the seat of tuberculosis, with very few exceptions the disease has been only slightly marked in that locality, while very advanced in the lungs and bronchial lymph-nodes. The great infrequency of primary infection through the alimentary tract is also shown by the experience of Northrup, who, in a series of 125 autopsies upon tuberculous children, mainly infants, found but a single case in which the infection appeared to have occurred in this manner, as against 88 in which it was clearly through the bronchial lymph-nodes.

"That bacilli may pass the mucous membrane of the intestine without producing disease in it, is not impossible. I have been looking for years for a case where the mesenteric glands were manifestly tuberculous, without tuberculous ulceration of the intestine, and I have yet to find the first one. Considering how extremely susceptible are the intestines of infants to other forms of infection, this contrast is rather surprising. The explanation of the difference seems to me to be this: Intestinal infection is nearly always secondary to disease of the lungs. Infants usually died from the more rapid tuberculous processes in the lungs or brain before there has been time or opportunity for intestinal infection to occur. The opportunities for such infection depend upon the number of bacilli which are coughed into the pharynx and swallowed. In infancy this number is small, because so many die of tuberculous pneumonia or meningitis before extensive softening in the lungs has taken place. In older children the slower course of the pulmonary disease gives ample time for intestinal infection, while the more extensive softening and excavation are accompanied by discharge of a much larger number of bacilli. I believe most strongly that all cows whose milk is used for food, whether for infants or older children, should pass the tuberculin test; and, further, that when the milk supply is from a doubtful source, milk should be heated to a sufficient degree—167 deg. Fah.—to destroy such bacilli, should they be present. Vastly more important is the enforcing of stringent rules regarding the isolation of persons with active tuberculosis, both in the home and the hospital, the careful destruction of the bacilli in the sputum from such cases, the disinfection of apartments after attacks, and most of all the early diagnosis of the disease in all persons who are brought into close contact with children, whether as nurses, teachers, or companions."

THE MILK FROM TUBERCULOUS COWS.

The matter under the preceding sub-heading is presented for the purpose of correcting the erroneous impression which is somewhat current, that the use of tuberculous milk and meat exerts a preponderating influence in the causation of tuberculosis. But, on the other hand, the object of that which is here presented is the correction of the opposite extreme opinion that there is practically no danger of infection from tuberculous milk, and that there is no evidence indicating that human beings have suffered infection from the use of such milk.

In a family of nine or ten children in Norway, Europe, two of the younger ones, aged one and three years respectively, died of tuberculosis, the younger one first showing mesenteric disease, and died of tubercular meningitis, the other, sixteen years of age, died of phthisis. There was no other history of tuberculosis in the family. The one cow which supplied the whole family with milk was slaughtered, and found to have tuberculosis of all the organs, the udder included.

Gosse, of Geneva, lost a daughter from intestinal and mesenteric tuberculosis. There was no family history of tuberculosis. Suspicion fell upon some of the cows whose milk the girl used to drink fresh from the udder. Four out of the five cows on the estate reacted to tuberculin, and were slaughtered. Two of them showed tubercular disease of the udder.

Professor Ropp, of the Iowa State College, cites the following case of transmission of tuberculosis by the use of the milk from tuberculous cows:—"Olivier reports that in a young ladies' boarding school five girls, the children of healthy parents, died of tuberculosis of the intestines. The cow which had for years supplied the school with milk was found to have generalised tuberculosis, including the udder. Two daughters of a Scotch family of good health who were brought up on milk of tuberculous cows died of tuberculosis. Two sons in the same family who did not use the milk remained healthy. Stang reports the case of a five-years-old boy of sound parentage and ancestry who died of tuberculosis. The cow whose milk this boy used was found badly tuberculous. Demme reports the

* The *Lancet*, II., 1894, 960.

cases of four infants in the Children's Hospital at Berne, the offspring of sound parents, that died of intestinal and mesenteric tuberculosis. He was able to exclude all other sources of infection and to decide that they had been infected by the ingestion of the milk of tuberculous cows. Hills mentions the case of a child twenty-one months old, of a friend of his, which drank the milk of a highly tuberculous cow for one week while on a visit to his uncle, and three months later this child died of intestinal tuberculosis. Other sources of infection could be excluded. A second child brought up on sterilised milk is still healthy. Hills also reports the death of a boy four years old at Yonkers, New York, from tubercular meningitis. The infection was traced to the milk of two cows of whose milk this boy had drunk, and which proved on autopsy to be tuberculous. Ernst reports the death of three children of one family from tuberculosis. These children had used the milk of a cow which later died of advanced tuberculosis, including the udder. Stalker and Niles report that five persons between twenty and thirty years of age of healthy ancestry died of tuberculosis within a period of two years. On the farm where these deaths occurred they found seventeen cattle suffering from tuberculosis, and other cattle had previously died of this disease. Leonhardt reports the death from tuberculosis of the meninges, intestines, and mesentery of two children fed on milk of a tuberculous cow. Sontag reports the case of a six-months-old child of healthy parents which died of tuberculosis, and which had been fed on the milk of a tuberculous cow. Hermsdorf has reported the case of a child dead of intestinal tuberculosis which had been fed on the milk of a tuberculous cow. Rich reports that a young man of healthy parents, who died of tuberculosis, had used plentifully of the milk of a herd of seventy-four cattle, sixty-five of which were tuberculous, some of them markedly so. Also, another young man died of tuberculosis. Two months later Rich destroyed eighty cattle out of the herd of the family, that is, about 90 per cent. of the entire herd. Also a young woman died of tuberculosis, and a month later the cow whose milk she had used died of advanced tuberculosis. Thorne reports that twenty-two physicians out of 339 practising in Ohio replied in the affirmative to the question, 'Have you been able to trace any cases of tubercular disease to the milk of unhealthy cows?' and that thirty-three replied affirmatively to the question, 'Have you had reason to suspect the origin of tubercular disease in older children or adults to be in the meat or milk supply?' This series of experiments and observations has been selected from literature with the greatest care. Any reports which appeared not to be well authenticated or of a doubtful nature have been excluded. Besides this mass of positive evidence there is much more, that, while not so positive, is not less convincing. It appears that the evidence collected by Thorne from physicians in Ohio is especially valuable, not only in itself, but because it indicates what might be learned by addressing the same series of questions to the physicians of all the States of the Union."

The numerous experiments of feeding animals with tuberculous food or other matter, establish firmly the reality of the danger from the ingestion of such material, so far as animals are concerned. Tuberculosis has thus been transmitted to animals, dogs, for instance, which have a greater power than man of resisting tuberculous infection.

In this country and in many European countries there has been a greatly increased prevalence of tuberculosis among cattle. This fact was brought out by Professor Bollinger at the Congress on tuberculosis which was held in Berlin last May. In connection with this matter he referred to the large increase in the prevalence of tuberculosis among swine, which is due largely to the feeding of the milk and milk-products of tuberculous cows, particularly the separator slime from creameries. In recent years from 60 per cent. to 70 per cent of some herds of swine in Northern Germany fed on this material have become tuberculous. Bollinger also says that in a large percentage—nearly one half—of the cases in which the milk from tuberculous cows has been inoculated into animals, the milk has been found to be infectious. The virulence of the milk is in general proportional to the stage of the disease in the animal furnishing the milk. It is not only in generalised tuberculosis of the cow that the milk is infectious, but in many cases of localised tuberculosis it has also been shown to be infectious.

Mosler touches the same subject with these words:—"Observation has shown that the distribution of tuberculosis among cattle and swine runs parallel with the development of the dairy business. In Denmark and Schleswig-Holstein there is the greatest development of this industry, and at the same time tuberculosis among animals and men is the most prevalent. There is apparently a casual relation between this excessive prevalence of tuberculosis and the feeding to animals of the waste products of the dairies. In swine, particularly, tuberculosis of the liver is very frequent (tuberculosis of the intestines.) In scarcely ten years the per cent. of animals which are affected with tuberculosis has risen from 2 or 3 per cent. to 30 per cent. The most potent factor in this increase of tuberculosis among swine has been the feeding of separator slime."

GLUCOSE AND ADULTERATED SYRUP.

Several small village shopkeepers were recently fined £5 for selling golden syrup not quality demanded. These fines were imposed in order to persuade defendants to take action against the wholesale dealers. The syrup was adulterated from 50 to 95 per cent. with glucose. Without doubt, these poor shopkeepers never heard of glucose.

Those who have to see to the enforcing of the provisions of the Food and Drugs Act seem to act in a most perfunctory and erratic manner, instead of going about their work in a steady, systematic, and rational way. At one time we have the Inland Revenue making a raid on the "four-ale" retailers, the local county analysts on milk, then vinegar, and now golden syrup; then things go on in peace for a time, until the officers under the Act apparently feel they must show that they are doing something to earn their sinecure salaries, and then they have a go at something else—mustard, for instance.

Adulteration in any shape or form is to be condemned, the more so when bolstered up by some incompetent chemist, who, without properly testing the article, declares it to be genuine.

There is far more glucose used in jam manufacture than in syrup, the sale of which, within comparatively recent periods, owing to cheap beetroot sugar, has decreased very much.

How some of the puffing chemists can certify that such a make of jam is make with the best sugar, when the makers in question may be the largest importers of glucose in the kingdom, passes comprehension. Glucose or potato sugar is not cane sugar, and everybody who buys jam buys it on the understanding that it consists wholly and solely of fruit and cane sugar. What about false trade marks put on by the manufacturers both of syrup and jam? What is sauce for the goose is sauce for the gander. If glucose-adulterated syrup is to be condemned, jam ought to follow suit. If the retail merchant is to be fined for selling the adulterated article, the manufacturer should be fined for imprinting a wrong trade mark thereon.—*Oil and Colourman's Journal.*

FORTHCOMING COOKERY EXHIBITION.

The Twelfth Universal Cookery and Food Exhibition will be held this year at the Prince's Skating Club, Knightsbridge, from June 11th to 15th, which promises to be one, if not the most successful Exhibition of its kind.

A powerful and influential Committee has been formed, and a substantial guarantee fund has been subscribed by prominent members of this useful association, whose main effort it is to spread a better knowledge of cookery among all classes.

The Exhibition is under Royal patronage, and has as president Mr. Burdett-Coutts, M.P.; as chairman Mr. J. C. Buckmaster, M.A., and as hon. treasurer Mr. J. Ménager, *chef* to his Majesty King Edward VII. C. Herman Senn will, as hitherto, act as hon. director.

Field-Marshal Earl Roberts, Commander-in-Chief, has given his special sanction for the troops within the London district to take part in the competitions, and as a result the Grenadier, Coldstream, Scots, and Irish Guards, and the Wiltshire Regiment, will take part, giving demonstrations of military barrack and camp cookery. Another interesting feature will be the mercantile marine competitions, in which present and past pupils of the Nautical Schools of Cookery of London, Liverpool, &c., will take part, also a number of boys from the training ships. This is just as it should be, for the questions of food and cookery, both in the Army and Navy, are of the utmost importance.

INSANITARY BAKEHOUSES.

Of all places a bakehouse ought to be pure (says Dr. Wm. Robertson, Medical Officer of Health of Paisley, in his annual report), clean, and airy. What one finds in many instances is a place so stuffy and close that breathing is difficult. The faults that presented themselves were as follows:—There was poor window light; the ventilation was not always of the best; indeed, in one or two it was at a standstill. Now and again I found the plaster work on the roof broken, and the lath bared. The floors were often in a miserable condition, and uneven. It was a perfect treat to enter some of the clean, well-tiled, and imperviously-paved floors of the modern bakehouses, of which there are some good instances. I think if every baker were asked to expose a photograph of his bakehouse it might lead to a good deal of very necessary reform. These are not matters upon which a Medical Officer of Health must keep silent. Silence is golden, I know, but health is more precious than silence. There is the health of the worker and the health of the consumer to be considered. I think it my duty to indicate that in many instances these might be much more easily safeguarded by an improved construction of some of our bakehouses. The law gives us very little power over these bakehouses. There are those, for instance, that can pass muster and no more, and there is another class that cannot be interfered with because they were erected prior to the framing of the Act that we desire to put into operation. I refer more particularly to underground bakehouses.

Other features of interest regarding the bakehouse I need not dwell upon. To cut a long story short, one was declared as unsuitable to be occupied any longer as a bakehouse. Its walls were in a broken-down condition, its floors were unpaved and had big holes in it. The walls were damp, and in every way the bakehouse did not comply with the requirements of the Act. In another case the factors were approached with a view to structural alterations so as to make the bakehouse comply with the Act. In two cases water-closet accommodation was called for in place of disgusting arrangements already in existence. And lastly, the alteration in the plan where a water-closet communicated directly with a bakehouse was demanded. In every instance, I am pleased to say, no objections were raised to the required improvements.

PATHOGENIC MICROBES IN MILK.

Klein describes the results of the bacteriological examination of 100 samples of milk, which were as follows:—

(1) Seven per cent. of the samples of "country" milk produced typical true tubercle in the guinea-pig.

(2) Eight per cent. of the samples of "country" milk produced typical pseudo-tuberculosis (non-acid-fast bacillus of pseudo-tuberculosis, A. Pfeiffer).

(3) One per cent. of milk samples produced diphtheria in the guinea-pig, yielding the typical *B. diphtheriæ*.

(4) One per cent. of milk samples caused a chronic disease (in most cases with fatal results) due to a pathogenic torula, apparently differing in cultural and physiological characteristics from the torula (pathogenic blastomyces) obtained by Sanfelice, Plimmer, and others from human cancer.

(5) Out of the secretions of the cow's udder two pyogenic microbes were obtained, *B. diphtheroides* and *Streptococcus radiatus pyogenes*.

Klein's figures for tuberculous milk (7 per cent.) accord fairly well with our own experience. Our figures have been as low as 7 per cent. and as high as 20 per cent. for different districts.—"R. T. H." (*Treatment*).

TUBERCULOUS MEAT.

Responding to the toast of "The Visitors" at the annual dinner of the Birmingham and District Butchers' Trade and Benevolent Association, Sir James Sawyer, in the course of his speech remarked that if they looked to the history of mankind to everything they knew about the nutrition of the body, they could safely say that the daily consumption of meat was an absolute necessity to the human being. He said this as a physician, as a physiologist, and a man of common sense. It was not as some people would like it, as idealists would frame it, but as Providence had made it. We had only to look at our mouths to see that we were neither vegetarian nor carnivorous animals, but both. This being so, it was to their interest as men of trade, to his as a man of science, that the meat should be pure and good, and in no way calculated to propagate disease. Difficult conditions had at times been imposed by the teachings of science. The medical profession had been sometimes carried away by enthusiasm, had sometimes made mistakes, but it had been actuated by the desire which actuated the members of that trade. Physicians felt that if they limited their work to attempting to cure disease they would be unworthy of their places in the community. They had tried in every way in their power to prevent suffering and disease, and whenever they had approached the trade fairly and honestly they had been received in the same fair and honest spirit. Butchers did not wish to live by selling meat at the expense of the health of the community, and during the last few years, with their co-operation, many improvements had been made. The speaker then alluded to consumption, especially in reference to its connection with the meat trade. It had been conclusively proved of late years, he said, that consumption was due to a minute organism, the tubercle bacillus, but it must not be thought that

tuberculous meat was the chief cause of the propagation of the disease. It was not. Consumption was chiefly transmitted by the inhalation of the germ into the human lungs from the expectoration of persons suffering from the disease, For this to be possible there must be two conditions, the vitality of the seed and the fitness of the soil. There was within those who were healthy and those who took care of themselves some power which could destroy the dread seed. Among the brute creation they found that bovine animals, and more especially cows—because they were "housed"—a special liability to the disease, and under certain conditions it might be transmitted to human beings. They were perfectly right in preventing, so far as possible, the sale of tuberculous meat, but even if it were consumed there was no surety of the propagation of consumption, because cooking was a great safeguard. He said this because, while not wishing to minimise the importance of a pure meat supply, he did not wish it to be believed that tuberculous meat was the chief agent in the spread of that disease.

THE SCIENTIFIC PRODUCTION OF MILK ON A LARGE SCALE.

Milk as a source of disease is well known, and its chief danger is its extreme liability to become infected with the tubercle bacillus. The conditions under which the production of milk is carried on, says the *Lancet*, are gradually passing from the old rule-of-thumb method to the scientific methods of the present day. This change, it may be remarked, does not only secure the production of milk of a non-infective character, but it has also brought greater economy into the methods and results. One of the largest examples of an enormous milk-supplying station in which the production of milk is dealt with scientifically on the score both of hygiene and economy is the establishment of Herr C. Bolle, in Berlin. From particulars recently furnished to us by Sir Otto Jaffe, who has studied the question of milk supply in a number of towns at home and abroad, we learn that Herr Bolle started his business in the year 1871, when he distributed 500,000 gallons of milk, whereas at the present day he supplies milk at the rate of 7,000,000 gallons to about 50,000 families. The milk is all sent out from one central station. The firm supply milk, cream, milk from a special farm for infants, sterilised milk, kefyr, machine-skimmed milk, buttermilk, butter, and cream cheese. In this great central station there are a bacteriological laboratory, a chemical analytical laboratory, and a chemical technical laboratory. In 1899 over 30,000 tests were made in the chemical analytical laboratory alone, and over 1500 guinea-pigs were used in the bacteriological laboratory, mostly for tests of tuberculosis. In the chemical technical laboratory experiments are made upon the by-products of milk which are utilised. Special officers are retained for supervising the 130 farms with their 14,000 cows which supply the central establishment, and the duty of controlling and observing the health of the cows is in the hands of four veterinary surgeons. Till a few months ago the firm passed the greater part of the milk which they collected from the various farms through filters of sterilised gravel which freed the milk of many of its impurities, destroyed many micro-organisms, and tended to keep the milk sweet. Within the last few months, however, they have made arrangements for using an improved pasteurising process for the whole of the milk which they receive with the exception of that which comes from one of their own farms, and they consider this to be one of the most important improvements that they have adopted since the opening of their establishment. They maintain that this process interferes neither with the taste nor with the chemical composition of the milk, but destroys the pathogenic microbes such as those of diphtheria, scarlet fever, tyhus fever, and particularly tuberculosis. The entire establishment, which includes butter, cream, and cheese manufacture on similarly scientific lines, covers more than five and a-half acres. The steam engines develop about 400 horse-power. The cooling plant is able to produce about twenty tons of ice a day. It is stated that the rapid growth of this industry has been accompanied with an excellent effect upon the general milk supply of Berlin; in 1879 14·1 per 1000 of the samples investigated by the police authorities were adulterated, in 1886 only 3·6 per 1000. The infant mortality per 100 living born children in 1871 was 30; this fell in the next 10 years to 27·1, and in 1899 it fell to 23·4. Even if it is also admitted that many other influences have contributed to the decrease of infant mortality, undoubtedly the improved milk supply has had much to do with it. The facts speak eloquently in favour of the scientific preparation and supply of milk and milk products.

HONEY AS A FOOD.

Sir James Sawyer, presiding over the annual meeting of the Warwickshire Bee-Keepers' Association on the 22nd ult., spoke in highest terms of honey as an article of food and also as a natural medicine. He ventured to think that the £70,000 worth of honey which was imported into England might well be raised by English people themselves, and it was a profitable industry. He knew it to be a most nutritious food, and an article to which more than a passing regard should be given.

"THE LANCET" on

VAN HOUTEN'S COCOA,

"In a recent analysis which we have made,
"the results distinctly indicate the advantage of
"VAN HOUTEN'S PROCESS of manufacture. Thus
"this Cocoa yields a maximum proportion of the
"valuable food constituents of the bean, and what
"is of more importance still, these are presented
"in a condition more easy of assimilation and digestion
"than in Cocoa not so prepared."

CASES IN COURT.

[RECORDS of Police-court proceedings for insertion in the "Food and Health" Supplement should reach us not later than the 10th of the month. Generally speaking, they should be as brief as possible, but where any important point of law is involved a fairly full report is permissible.—ED. S. R.]

Poisonous Mussels.

GEORGE YAXLEY, a Yarmouth fish hawker, was recently summoned for exposing for sale unwholesome mussels. The presiding magistrate was Mr. J. T. Bottle.

The TOWN CLERK, who prosecuted, said that some time since the Corporation became aware that mussels from the river and Breydon water were liable to cause symptoms that gave rise to typhoid fever, and a notification was accordingly issued prohibiting these being sold under a penalty, should such mussels be found to be unwholesome. A purchase was made of a couple of quarts of mussels from defendant's shop at 2d. per quart, the usual price of Stiffkey and other sea mussels being 4d. When these mussels were opened the *colon bacilli* was found which was the forerunner of typhoid fever. In one cubic centimetre of the water inside the mussels there was ascertained to be 803,200 bacteria, which showed that each mussel would contain about 3,000,000 bacteria. The mussels were seriously contaminated, and condemned by a magistrate afterwards as unfit for human food. The Town Clerk said he desired the Bench to support the action of the Corporation. It was absolutely necessary to prevent the population of Yarmouth contracting disease from unwholesome food. Mussels in the river and Breydon water were polluted with sewage, and that fact of itself was sufficient to render them unwholesome. There might be some sympathy with defendant in this case on the ground of ignorance, but this plea could not be advanced in future.

Inspector Hassell described the purchase of the mussels, which he said were small and dirty, resembling river mussels. He sent a sample to Dr. Pakes at Guy's Hospital, London, exhibited the others to the Medical Officer of Health, and afterwards to Mr. S. W. Spelman who, as a magistrate, condemned them.

Dr. Russell, the Medical Officer of Health, said he had examined the conditions under which mussels in in the locality grew, and he considered them unwholesome food. Undoubtedly there had been cases of typhoid fever attributable to these mussels. He inspected those obtained by the Sanitary Officer, and they were sewage polluted. He caused warnings to be issued by bills posted throughout the town.

The TOWN CLERK said this was as far as he could carry the case that morning, as Dr. Pakes could not attend. It was hoped that in the near future they would be able to make these bacteria examinations locally and obtain the information for the Bench.

Mr. T. Green: From your knowledge of these mussels do you consider they are of a highly poisonous nature?

Dr. Russell: I do, certainly.

The CHAIRMAN: What have you to say?

Defendant: I catch these mussels in clear water up Breydon, three miles from Yarmouth Bridge.

The CHAIRMAN: But the evidence is that they are very poisonous.

Defendant: I did not know it.

The CHAIRMAN: This is the first case and we shall not punish you. We hope it may be conveyed through the Press as a warning that these mussels are as poisonous as anything can possibly be, and likely to

cause disease. Therefore, if anyone else is found offering such mussels for sale they will be dealt with severely, because the health of the inhabitants of the borough is at stake.

THE EXPERT'S CERTIFICATE.

Dr. Walter C. C. Pakes, D.P.H. (Camb.), F.C.S., of the Public Health Laboratory, Guy's Hospital, in his certificate, said: "On February 20th, I received a tin containing a number of mussels. Upon arrival the box and its contents were quite cold, the temperature during transit, upon February 19th, being low. The mussels were, so far as the naked eye appearances could show, sound. Eight of the mussels were selected from different parts of the box, in order to avoid examining those which had been lying together. They were all opened under strictly antiseptic conditions, and from each mussel was taken either some of the water contained in the shell, or a portion of the mussel after it had been cut free from the shell and washed in sterile water. From two mussels the water was examined, and portions of six mussels were treated in the manner described. From each sample of water and from each portion of mussel typical *colon bacilli* were isolated. The number of bacteria present in one cubic centimetre of the water in the shell was 803,200. There can be no doubt that the mussel beds from which these mussels are taken are very seriously contaminated with sewage matter, and the mussels themselves must be looked upon as dangerous to the health of those who consume them."

Bad Meat At Burslem.

At the Burslem County Police-court a butcher named Henry Clarkson, of Wetley Rocks, was charged with having exposed bad meat for sale in the Burslem Meat Market. The prosecution was instituted by the Corporation, and conducted by the Town Clerk (Mr. A. Ellis), while Mr. E. A. Ashmall was for the defendant.

Wm. Martin, Sanitary Inspector to the Burslem Corporation, said that he saw a carcase of beef on the stall of the defendant in the meat market. The meat was wet, soft, emaciated, and poor, and was without fat. Certain portions of the carcase had been removed, including the pleura and the diaphragm. The defendant told him that the meat was that of a Cheshire cow which had cost £8, but had "done bad." The total weight of the meat exposed was 419 lb., and having seized the meat the witness had it examined by Mr. Wood, J.P., who condemned it. The meat was also examined by several persons, and in the presence of the defendant on Saturday a large tumour was removed from the breast bone. The following day other tumours were removed from the meat, showing that the beast had suffered from tuberculosis. The kidneys smelt very badly, and one of them was diseased.

Mr. J. T. Allen, veterinary surgeon said he had examined the meat exposed by the defendant. It was soft and badly nourished, and all through the glands there were tubercular growths. Dr. Youngson also gave evidence, confirming the previous statements as to the prevalence of tubercular nodules, and expressing the opinion that the meat was quite unfit for food.

Mr. J. Sargeant, a butcher, who was present when the meat was examined by the Inspector, said that the meat was in such a condition that a butcher could at a glance see that it was unfit for food. A labourer, Leonard Johnson, who was present when the defendant slaughtered the animal, said that when the udder was cut a mattery kind of milk issued.

Mr. Ashmall urged the magistrates to deal as leniently as possible with the defendant, who had lost the sight of one eye, was suffering from an injury to his hand, and his general condition was poor.

It was shown by the police record that the defendant had been convicted of a similar offence eleven years ago.

Mr. Brough said this was as bad a case as had been before the Court. When meat of such a diseased nature was sold, the health of a very large number of people was threatened. The prisoner would have to go to prison for three months, and to pay the costs. In default of the payment of the costs another month's imprisonment would be added.

Glucose in Marmalade.

George Smith, a grocer of Worthing, at the West Sussex Quarter Sessions at Horsham, appealed against his conviction by the local magistrates for selling marmalade adulterated with 13 per cent. of starch glucose.

Much scientific evidence was given for and against the contention that glucose was not injurious to health.

Mr. Thomas Francis Blackwell, chairman of Crosse and Blackwell, deposed that seven years ago his firm found that there was a public taste for jams with glucose, and they were bound to meet it.

Mr. Thomas Pink said his firm had for twenty years used glucose, which greatly improved jams.

The Bench decided that the conviction must be upheld. They did not consider that glucose was injurious to health, but the added substance constituted an offence within the section of the Act.

The Bench agreed to state a case.

Unsound Veal in Glasgow.

At the Central Police-court, Walter Keir, 32, York-place, Perth, pleaded guilty to having consigned a calf which was unfit for human consumption to James Anderson, meat salesman, Glasgow.

The agent for the defence admitted that the calf was lame; that it was imperfectly bled; and that it had been slaughtered in his own premises instead of in the public slaughter-house in Perth, but tendered the excuse that his client was ignorant of the laws.

The Fiscal pointed out that in this case the whole of the internal organs had been taken out, this being against the usual practice of the trade.

Judge Battersby imposed a penalty of £5, with the alternative of thirty days, and remarked that the health of Glasgow must be considered, and if accused was ignorant of the laws it was his duty to make himself familiar with them.

How to Choose a Fish.—A fish-market man gives this simple rule for fish buyers to follow if they would secure fish that is eatable and certainly free of the ptomaines of which so many fish lovers stand in dread: See that the flesh is so firm that it will not be dented on pressure by the fingers, that the eyes are full, the scales bright, the fins stiff, and the gills are of the brightest, neither pale nor a dark liver colour. Then, if there is no odour to the fish, it may be eaten with safety.

Formaldehyde Gas for Disinfecting Books in Libraries.—For some time past the belief has been current that diseases are contracted by handling books in public, which have become infected with the germs of some disease. The New Jersey Authorities have been the first to take preventive steps, owing to a case of scarlet fever, which had been shown to be transmitted by the agency of a book in a travelling library. Professor Mitchell, of the New Jersey State Board of Health, has been conducting a number of experiments with formaldehyde gas, using kindergarten toys and public school books, and so far it has been found the surest destroyer of microbes, working quickly and effectively.

FOOD ADULTERATION IN ITS RELATION TO THE PUBLIC HEALTH.

Among the many factors which have a great influence upon the health of the individual there is none more potent than food.

Often even wholesome foods may be administered in such a way or in such excessive quantities as to injure the health of the consumer. If this be true, how much greater must the danger be if the food offered for consumption be changed in its nature, so as to become a positive poison, by the addition of foreign bodies?

It is well known that flour made from wheat has been largely adulterated by the addition of purely starchy matter derived from Indian corn. Now, starch cannot be regarded as injurious to health, and hence the addition of a starchy body to the flour of wheat is in this sense not an injury. Physiological chemists, however, have discovered that there is a certain balance in the foods of man which should not be disturbed. In other words, there is a definite relation between the quantities of proteid, fat, and carbohydrate matters which, when sustained, renders this mixed food most nutritious, and therefore most economical. Bread made from wheat flour, especially if it be made as nearly as possible from the whole grain, is recognised by physicians and physiologists as being practically a complete human food, with a certain definite ratio existing between the proteid matter which it contains and the fats and carbohydrates. It is evident at once that the addition of other starchy matter will disturb this ratio and thus render the food less economical, by increasing enormously one of its constituents without changing the quantities of the others. For the ordinary healthy stomach such a change in the food would be of no consequence whatever, but we can readily imagine cases where with the disturbed digestion and imperfect secretion of the enzymes which produce fermentations characteristic of the digestive process, the increase in the amount of starch would produce a positive injury. We know that starch is digested first in the mouth by the action of the enzymes of a diastatic nature, secreted by the salivary glands. The slight alkalinity of the digestive fluid favours the action of the salivary enzymes. When the food reaches the stomach, in natural digestion, it becomes acid under the action of the hydrochloric acid secreted by the glands of the stomach. The enzymes of the peptic ferments are also secreted in large quantities, and act rapidly upon the proteid matter of the food, converting it into peptone. This action is favoured by a slight acidity. It is evident, therefore, if the digestion of the starch does not proceed under the most favourable conditions in the stomach, any excess of starchy food may interfere seriously with proteolysis. In other words, the amylolytic ferments and the proteolytic ferments do not reach their maximum activity in the same environment. The mixing of Indian corn starch, therefore, with wheat flour, while it is an adulteration of the first class, being the addition of a harmless or innocuous substance, may in the cases mentioned above become a positive injury to health.

Another illustration which may be cited is in the case of the glucose of commerce. Now, the glucose of commerce is a mixture of dextrose and dextrin with a small quantity of maltose, produced by the artificial hydrolysis of the starch under the influence of an acid. It is well known that the starch in foods must undergo a similar hydrolysis, under the action of the diastatic ferments of the digestive organisms, before it can be assimilated and act as a nutrient for the body. From this fact it might be inferred that a partial previous digestion of the starch, by an artificial hydrolysis such as is referred to above, might be of advantage. This, however, cannot be seriously admitted. It is a well established principle in physiology that the disuse of organs tends to produce atrophy and eventually functional paralysis. Hence, if the starchy foods are replaced by artificially digested starch, the organs which produce the diastatic ferments to hydrolise the starch are deprived of a part of their functions and must suffer from disuse. It is evident, therefore, from this point of view, that the use of predigested starch is to a certain extent prejudicial to the health of the digestive organs. Where the digestive ferments are deranged and the digestion of starch rendered difficult, the addition of predigested foods may be useful, but these should not be substituted for the natural foods, except on the recommendation of a competent physician. Again, there may be objections to the use of glucose from another point of view. This substance is, as is well known, largely used as an adulterant for honey and jelly. Honey owes its value to the peculiar flavour which it possesses, due to the aromatic substances derived from the flowers, and possibly to traces of formic acid obtained from the digestive organs of the bee. In other words, honey is not prized simply because it is a carbohydrate, but because of its flavour. Whenever, therefore, glucose is added to honey, by the substitution of it for the aromatic substance above mentioned, the peculiar flavour is destroyed and the honey is to that extent less desirable. So here is another instance in which the introduction of a perfectly harmless substance into food may render it positively injurious.

When we come to the second class of adulterations there is less ground for dispute. No physician will fail to condemn the use of bodies in foods which are positively injurious. The excuse usually urged for the use of these bodies is that they are in such minute quantities that they cannot possibly be injurious. This I readily grant is valid for healthy stomachs, of individuals who are in the prime of life and who are in the full possession of all their powers, but it can hardly be general in its application.

Adulterants of this class are best illustrated in the use of preservatives. For economical reasons foods are not always consumed on the spot where they are produced nor at the time of their production. Many foods are of a perishable nature, and if not consumed at the time of their maturity are lost. To render these foods serviceable through the entire year, and in localities widely separated from the place of their origin, some method of conservation must be employed.

There are two methods of food preservation which are perfectly natural and permissible. One consists in the complete desiccation of the food so as to prevent the fermentation which produces decay.

The second method is to subject the food to a Pasteurising or sterilising temperature for a time sufficiently long to destroy the germs of fermentation. The foods thus Pasteurised or sterilised are prevented from coming into contact with the air, and thus by excluding the fermentative germs they can be preserved indefinitely. Both of these processes are to a certain extent troublesome and expensive, and hence dealers in foods have sought to accomplish the same result by a shorter and easier course, namely, the employment of certain chemicals which have the property of retarding, paralysing, or destroying the activity of the fermentative germs. All food preservatives act essentially in the same way.

It is well known that there are a great many substances possessing neither taste nor odour which have this retarding action upon the fermentative germs. The addition of these bodies to foods secures their preservation and at the same time does not impair their flavour. Among the preservatives which have been commonly employed in this way may be mentioned sodium sulphite, boracic acid, borax, potassium nitrate, sodium chloride, sodium silico-fluoride, potassium fluoride, sulphurous acid, formaldehyde, salicylic acid, benzoic acid, abrastol, and saccharin. A glance at these substances will show

that they are of two general kinds, those of an inorganic nature, which are mentioned first, beginning with sodium sulphite, and those of an organic nature, beginning with formaldehyde.

It will be noticed that some of the bodies in the first class are of a condimental nature, and therefore cannot be rigidly considered as food preservatives. We must not exclude from foods the condiments with which we are familiar. They are necessary and desirable, although being of themselves of little food value, and hence the use of any one of the bodies mentioned above, in a condimental sense, cannot be considered reprehensible. Those which are most commonly used as condiments are common salt and potassium nitrate, the latter, however, to a very limited extent.

In the second class the only one which is used in the condimental sense is saccharin, and that only as a rule in the case of persons suffering from diabetes, where the use of a carbohydrate in the food is deemed inadvisable, and where the patient craves a sweet taste in his food.

In general it may be said that all decay of foods is due to germ action. It was at one time supposed that the decay of organic matter was due to oxidation of the air, but since the time of Pasteur this idea is no longer entertained. The sole function of the addition of preservatives, therefore, is to paralyse or suspend the germ action and thus preserve the foods from decay. On the other hand, we should not forget that the process of digestion is essentially a fermentation from beginning to end. The splitting up of the organic food elements in simpler forms, which can be assimilated and utilised in the system, is due solely to the action of ferments belonging to the general class of enzymes.

The decay of foods is due to fermentative action, caused by organisms capable of reproducing their kind, and to the enzymes which are secreted by the living organ. The process of digestion in the alimentary canal is due almost solely to the latter cause, the action of the germs capable of self-reproduction being extremely limited, and even doubtful. It may be stated, however, that any substance which has the property of suspending or retarding the action of germs capable of reproduction has a similar action upon the enzymic ferments. Therefore it follows that when these substances which are added to preserve foods reach the alimentary canal, their paralysing action will continue during the process of digestion. Hence this broad principle should be enunciated as being definitely established, that all substances which are capable of preserving foods have also the property, to a certain extent, of retarding the processes of digestion.

The question therefore arises, Should the use of preservatives in foods be absolutely prohibited? So far as the public health is concerned, it would be sufficient to permit the use of the least harmful preservatives, on the condition that the kind and amount of the preservative employed be marked in plain letters on every package containing it.

It is claimed by many competent hygienists and physiologists that a moderate use of borax or boracic acid in butter is of a condimental as well as of a preservative nature, and does not in any way tend to interfere with the process of digestion. Claims made in this manner are worthy of consideration.

There is one other form of food adulteration to which the attention of this body should be called, and that is the artificial colouring of foods. Artificial colours are now used to a large extent in human foods, chiefly in butter and oleomargarine, canned meats, and preserved vegetables. Butter and oleomargarine were formerly coloured yellow with turmeric. The introduction of the coal-tar dyes provided a cheaper colouring matter, and one of the azo dies, tropæolin, which gives a bright yellow colour and at a smaller expense, has almost entirely replaced the vegetable colouring matter first mentioned. As a result of this use, turmeric has practically disappeared from the dairy and the synthetic yellow has taken its place. Coal-tar compounds should be regarded as practically in the same category with the organic preservatives above mentioned.

For the colouring of sausages and preserved meats the coal-tar products are chiefly employed. The following is a list of some of the colours which have been used:—Bismarck brown, buffalo brown, double scarlet fuchsin, and a red colouring mixture composed of common salt, sodium nitrate, borax, and carmine.

The addition of nitrate of soda and nitrate of potash to sausages and meats tends to preserve and at the same time to intensify the red colour of meat. Potassium nitrate is uniformly employed by all packers of corned beef, so that it may be considered as a normal constituent thereof.

The green colour of peas and beans and other green vegetables, which are preserved by sterilisation, is fixed by the use of zinc and copper salts. These bodies act as a mordant, entering the tissues of the green plants and fixing the chlorophyll, by preventing its transformation into xanthophyll, which would otherwise occur on long keeping. Green peas which are Pasteurised without the addition of zinc or copper become yellow by the production of xanthophyll, while if zinc or copper salts be employed the green colour is preserved indefinitely. It is well known that zinc and copper salts are not particularly wholesome, hence their use in preserved vegetables is to that extent reprehensible. How far we should sacrifice our æsthetic ideas, as to what food should look like, to purity, must be determined by each one for himself. It would be a sufficient protection to the public to require that every package of preserved vegetables containing copper and zinc salts should have that fact plainly marked upon the label.

Examples of food adulteration which arise from the extraction of some valuable ingredient from the food, and the substitution of a less valuable ingredient, are also very numerous. In the removal of cream from milk inspection is so rigid as to practically prevent adulteration. The laws of most of our large cities require that the milk offered for sale shall contain not less than a certain quantity of fat; the minimum limit is usually three or three and one-half per cent. The content of fat in the milk from a Jersey herd of cows often reaches five per cent. It is thus seen that the thrifty dealer can remove two-fifths of what the natural milk contains, and yet sell his article in conformity with the statute. Nevertheless, the removal of this amount of fat is in every sense of the word an adulteration, and should receive the same punishment as if it were extended until the limit fixed for the fat had been transgressed.

The use of skimmed milk in cheese-making, with the addition of lard and cottonseed oil, is another illustration. Another common substitution is that of cottonseed oil for olive oil, which has been practised to an enormous extent in this country. This is a clear case of adulteration which is not injurious to health. Cottonseed oil is perfectly wholesome, as much so as olive oil.

The fraud in this instance is purely a monetary one, but the offence is just as great, and the punishment should be as severe.

From this brief summary of some of the methods of food adulterations it is clearly seen that the practice of frauds of this kind is usually more to be regarded from a monetary point of view than as prejudicial to the public health.

The sole objects of food adulteration are to sell an inferior article at the price of a superior one, and to preserve a good article so that it can be sold after preservation at the same price or at a higher price than it would bring in its natural fresh state; and to secure this object reprehensible methods are employed.

Foods should be sold everywhere for what they are,

while the greatest liberty is granted in their manufacture and preservation compatible with the public health. Only where actual injury is done should prohibition be practised, but up to this point a plain marking of the food containing preservatives or adulterants of any kind would be entirely effective.

MILK CONTAMINATION AND HOW BEST TO PREVENT IT.

In order to fully appreciate the painstaking work necessary to prevent milk contamination, it is requisite that all the details of its production and transportation be thoroughly understood, as well as the element of time taken in handling it taken into consideration, for it is well known that milk of a very good quality soon deteriorates, even where the most perfect practical methods are used for its preservation.

The subject may conveniently be arranged under two divisions, namely:—First, Methods of contamination; secondly, Prevention of contamination. First, Methods of contamination can be subdivided into (*a*) diseases affecting cow, her food and surroundings; (*b*) contamination while being milked and prepared for shipment at the dairy; (*c*) while being transported and delivered to consumer; (*d*) after milk is in consumer's possession. Secondly, Prevention of contamination covers a wide field, and can only anywhere near approach perfection by constant, intelligent supervision from the pasture field, watering place, and food trough to its final delivery to the consumer, and after it is in the consumer's hands, by general education of the masses in hygiene in general.

In regard to diseases liable to affect the cow, of course tuberculosis holds first place, and in some localities seems to be present to an almost alarming extent.

It is a well-known fact that a cow can be affected with tuberculosis and yet give non-tubercular milk; in fact, is not liable to do so unless extensive general tuberculosis be present, or else tuberculosis of teats, milk glands, or udder exists. It would seem the sensible thing to do, to examine milk and destroy the animal only when she gives milk containing tubercle bacilli, instead of the expensive, not to say questionable, proceeding of slaughtering them because they react to the tubercle serum.

Is there great liability to contract tuberculosis from the use of milk that occasionally contains tubercle bacilli? Or, putting it more strongly, is tuberculosis disseminated in the human being by use of tuberculous cow's milk?

We have no direct evidence of such a result, and the bacillus found in cow's milk is not exactly the same as that found in human tuberculosis. Primary intestinal tuberculosis is uncommon in the human being, which would not be the case if it was at all generally produced by milk consumption. Hydrochloric acid or gastric juice is very destructive to the bacillus, and probably under ordinary conditions few, if any, pass through the stomach alive, and, providing some do, they hardly would infect from the intestine if mucous membrane was intact. We do not deny the possibility of infection, but the practical question is, how large a proportion of those using tuberculous milk become affected? This can only be answered, in the light of facts before us, by saying that there are not nearly as many as alarmists would have us believe. The writer's opinion, based upon years of observation, is that children who consume much milk during early life, say up to fifteen years of age, are better equipped physically, having less skin and digestive diseases, and really have a lower mortality from all causes, tuberculosis included, than those deprived of this useful food. Cattle are, of course, liable to acute diseases, but, fortunately, give but little milk during an attack, and the same may be said of most chronic diseases, tuberculosis being the main exception. The disease of milk glands known as garget is quite common, and the average farmer thinks such milk not sufficiently bad to warrant throwing it away, and into the can it goes.

New milk (that is the secretion of milk glands for first two or three days after dropping calf) is not generally considered fit for use, but quite generally goes in to enrich the mass sent to cities.

Milk, sometimes even deadly in its virulency, is many times the result of food taken. Digestive diseases are most common during periods of drought, when cattle are obliged to eat weeds and plants which they avoid when grass is abundant. Those fed on malt and refuse from breweries and distilleries come under the same heading. There should be care of the cows not only in regard to food and water, but also in relation to construction of stables, ventilation, light, bedding, condition especially of stable floor (the latter often are afloat on a reeking mass of filth in latter part of winter and spring months, and in such cases the cow is usually pretty well plastered). This is not overdrawn, but is supported by facts altogether too numerous. Can milk from cows in such surroundings be a good article?

Probably the most prolific source of contamination occurs while milking is being done. Who ever heard of a milkman washing his hands before milking? Most of them wait until they are actually doing the work, and then wash them in the milk. Many milkmen think they cannot milk without first wetting teats with milk, and consequently persist in this filthy habit. Water is not usually handy to milkyards or stables, consequently udders and teats rarely get washed.

The cow is a restless creature, especially inclined to be uneasy while being milked, occasionally kicks and now and then plants a filthy foot in the milk pail. (Such milk is usually strained before going into the can.) Hair, insects, hay, straw, blood, pus, particles of earth, and more or less cow manure constitute the most common foreign elements that get in at this time. It cannot be entirely prevented, but can be very much lessened if only more care were taken, and result of the evil more generally appreciated. Also, at this time, milk often has been made deadly by contamination with disease germs. They get into the milk in a variety of ways; most common, perhaps, is that by washing utensils with infected water. Scarlet fever, diphtheria, and typhoid are no doubt often produced by the use of milk so infected. Scarlatina is unknown in countries where cow's milk is not used for food, which many authorities think is due to this source of transmission being absent. A common source of trouble comes from improper cleansing of utensils at this time, minute particles adhering to cans, pails, &c., being a nidus for rapid bacterial development in fresh milk that is added. Milk may contain enough butter fat, solids, be strained, and yet be very bad from this cause alone.

Methods of contamination while in the hands of the dealer are mainly from removal of covers from cans for various purposes, thereby allowing particles of dust and various other minute substances to gain entrance, and quite generally such substances favour bacterial development. After the milk is in hands of consumer the methods of entrance of impurities are many; the most common are from unclean dishes, keeping in living rooms, exposure to disease germs, and lack of proper facilities to keep correct temperature.

Methods of prevention of contamination that might and should be faithfully and earnestly carried out are many. Hygienic laws that are useful generally are especially useful here, and when more generally understood, milk inspection will be greatly simplified.

Examinations for germs aside from tubercle would not be necessary if the foreign substances were kept out.

It is not that the producers and handlers of milk do not understand these matters generally pretty well, but they are careless about their proper enforcement; they do not fully realise the great disaster that might easily follow carelessness or dishonesty in any minor detail.

The trite saying, "Eternal vigilance is the price of liberty," might apply here if changed to "Eternal vigilance is the price of pure milk."

CASES IN COURT.

[RECORDS of Police-court proceedings for insertion in the "Food and Health" Supplement should reach us not later than the 10th of the month. Generally speaking, they should be as brief as possible, but where any important point of law is involved a fairly full report is permissible.—ED. S. R.]

Milk Adulteration and an Appeal.

THOMAS RICHARDS, of Fetter-lane, London, was summoned recently for selling milk adulterated with 18 per cent. of added water.

Mr. HENRY CORBETT JONES, Town Clerk to the Metropolitan Borough of Holborn, appeared in support of the summons. Mr. E. O. JONES defended.

On the last occasion the defendant produced the certificate of an analyst to whom he had submitted the sample which, in accordance with the usual arrangement, was left with him. The analyst reported the milk to be of rich quality, and the summons was adjourned for the third sample to be examined by the Somerset House analyst. That official now reported that the milk was diluted by at least 18 per cent. of added water, but he added that the sample bottle containing it was sealed in such a way as to enable the stopper to be removed and replaced without breaking the seal or cutting the string.

The Solicitor for the defence contended that all the milk vendors in London would be in peril if their cases were to be decided on milk contained in bottles the stoppers of which might be removed at pleasure.

Evidence was given to show that neither of the samples relied upon by the prosecution could have been tampered with in any way. The Magistrate ordered the defendant to pay a fine of £20 and 12s. 6d. costs.

Notice of appeal was given.

Pure Country Milk.

AT the North London Police-court, Henry Hollier, a farmer, of Street-hill Farm, Twyford, Leicestershire, was summoned, before Mr. FORDHAM, at the instance of the Islington Borough Council, for sending milk to London which was adulterated.

Mr. BRAMALL prosecuted for the Council, and Mr. SIMPSON defended.

Mr. Alfred Ray Abbott, member of the firm of Abbott and Son. milk contractors, of Digby-road, Homerton, said that on October 4th, 1900, his firm entered into a contract with defendant for a daily supply of milk, which was to be pure and have the full amount of cream, and which was to be delivered at the Finsbury Park Station. In consequence of one of the firm's customers having been fined at that Court for selling adulterated milk, the Sanitary Authorities were communicated with.

James Cowling, one of the inspectors employed by the Islington Borough Council, said that in consequence of the last witness's communication he visited Finsbury Park Station on the 12th, 13th, and 19th of March, and on each occasion took samples of milk which had been consigned by the defendant to Messrs. Abbott. The first sample contained 22 per cent., the second 33, and the third 35 per cent. of added water. On March 19th the witness was at John o' Gaunt's Station, near Twyford, and he saw the defendant arrive with three churns of milk. He took samples from each. Two of the churns turned out to be perfectly right, and the third (churn 6004) showed adulteration to the extent of 35 per cent. of added water. The defendant said that this churn came from another farmer named Pym, and he also mentioned the numbers of the churns from which the adulterated milk had been previously taken as having come from the same person. In consequence of this statement the witness communicated with the Sanitary Authorities at Melton Mowbray, and a sample was taken of milk which Pym meant to go with the defendant's milk to London. This on analysis was shown to contain 40 per cent. of added water. For this Pym was fined £5 at Melton Mowbray.

Frederick Pym, grazier, of Twyford, in reply to Mr. Simpson, said that he was in the habit of selling Mr. Hollier a quantity of milk daily to make up the quantity he had to supply to Abbott's. The defendant paid him what he received, only deducting 1d. per gallon for carriage to the railway station. The witness did not dispute the assertion that the milk in the condemned cans had been supplied by him, but some of the defendant's milk had been added.

Mr. SIMPSON: Thus improving the quality. I can from the books show the exact amount of my client's milk in the churns each day, and comparing this with the percentage of 40 per cent. of added water in the milk found on Pym's premises, it entirely proves what I say.

Mr. SIMPSON added that the defendant was a man of

Has the Charm of being always Nice, and it is also an excellent Digestive.

A Free Sample.—**A Voucher for a Dainty Small Hovis Loaf will be gladly sent on request. — The HOVIS COMPANY, Ltd., Macclesfield.**

"THE LANCET" on

VAN HOUTEN'S COCOA,

"In a recent analysis which we have made, "the results distinctly indicate the advantage of "VAN HOUTEN'S PROCESS of manufacture. Thus "this Cocoa yields a maximum proportion of the "valuable food constituents of the bean, and what "is of more importance still, these are presented "in a condition more easy of assimilation and digestion "than in Cocoa not so prepared."

the highest respectability, and although he was technically liable, he was the victim of Pym.

Mr. FORDHAM said that he believed Hollier was more sinned against than sinning, and that he had been taken in by his neighbour. Had he believed that the defendant had watered the milk, he should have imposed the full penalty in each case. As it was, on one summons he would have to pay £1, with £7 7s. costs, and on each of two others 5s. with 12s. 6d. costs.

Exposing Diseased Meat at Northampton.

THOMAS WILLIAM STILL, butcher, 5, Marefair, was summoned for exposing for sale, on the 9th ult., beef unfit for human food.

Mr. W. B. SHOOSMITH prosecuted on behalf of the Corporation, and Mr. G. JASON PHILLIPS defended.

Frank White, Inspector of Nuisances, deposed to visiting Still's premises about midday on the 9th, and to seeing there four pieces of beef which were obviously unfit for food. The beef appeared to have been taken from an emaciated carcase; the lining membrane of the ribs was stripped, and a small portion of that which remained bore traces of tubercular disease. Witness seized the meat and took it to the Health Officer, where it was condemned by a magistrate and destroyed. The total weight was 38 lb. When witness seized the meat, defendant said that the meat was all right, and that it came off an animal which he had bought as "a blown cow." A blown cow was an animal which was suffering from tuberculosis, and which had been fed on dry food. Still stated that the cow cost £5. A cow in ordinary condition would cost £12.

By Mr. PHILLIPS: Three of the four pieces of beef which witness seized were fully exposed for sale, hanging over the window-board in fact.

Mr. Lee F. Cogan, Medical Officer of Health for the Borough, deposed that the meat was in a diseased condition, and decomposition had set in. Witness had to remove pieces of fat to discover some of the traces of disease. The fat appeared to be that of a healthy animal. The meat was certainly not fit for human food.

For the defence, Mr. PHILLIPS said that Mr. Still bought the animal, which no doubt was ailing, suffering from tuberculosis, but after it had been properly slaughtered it was exhibited in Mr. Still's shop, in the most prominent place in which it could be exhibited, and part of it was eaten by Mr. Still's wife. What better proofs of good faith on the part of the defendant could they have than those? Until a recent date, the carcase of an animal which had suffered from tuberculosis was not regarded as unfit for human food. Defendant had acted in good faith, although he might have been more cautious.

Mr. Spokes, farmer, Upton, said that after a veterinary surgeon had pronounced the animal, on March 28th, to be suffering from indigestion, he sold it to defendant on April 1st. Witness saw the carcase and considered it good for human food. Witness did not observe any traces of disease on the meat; it was certainly a bit "grapy."

Cross-examined: Witness did not know until that morning that "grapes" and "tuberculosis" were identical.

James Groom, the butcher who dressed the beast on April 1st, said that when dressed the meat appeared "good enough for any one."

Arthur Grissell, another butcher, did not think there was anything to complain of as to the state of the meat.

Defendant deposed that, so far as he knew, the meat

was fit for human food. Witness sold some of the meat to his wife's father and mother.

By the BENCH: Witness sold a side of the beast to a butcher named Robbins.

The Chief Constable, in answer to the Bench, stated that in July last defendant was fined 40s. and costs for exposing unsound meat on the Market-square.

Fined £5 and costs.

Foreign Butter and Alleged Adulteration.

AT the Thames Police-court the Anglo-Continental Produce Company, of Tooley-street, Southwark, were summoned before Mr. MEAD, for importing into St. Katherine Dock, butter which had been adulterated with not less than 10 per cent. of fat other than butter fat, and the package was not conspicuously marked with the name or description indicating that it was adulterated, contrary to Sec. 1 of the Food and Drugs Act, 1899.

Mr. DALBY and Mr. R. S. ROBERTSON, instructed by the Solicitor of His Majesty's Customs, prosecuted; and Mr. MACMORRAN, K.C., and Mr. RICARDO appeared for the defence.

For the prosecution it was stated that on the 4th of February last the steamship Viola came into the St. Katherine Dock from Hamburg with a mixed cargo, amongst which were two consignments of so-called butter. Samples were taken in accordance with the directions of the section, and a sample was analysed by Mr. Lewin, Chief Chemist of the Government Laboratory. That gentleman, on examination, found that the consignment contained more than 10 per cent. of fat other than butter fat.

Mr. MACMORRAN, K.C., on behalf of the defendants, said the case was one of considerable importance, and was the first under the new Act of 1899, which rendered the consignee liable to heavy penalities if the article was found to be adulterated. It was, therefore, necessary that the utmost care and attention should be bestowed on the case. In addition he should be in a position to show that the standard laid down by Mr. Lewin would practically exclude from the markets of this country Russian and Siberian butter, in which a very large trade was done. While not wishing to introduce anything to suggest that Mr. Lewin had not made a proper analysis, he should show different figures given by persons of high reputation, and these would prove that the result was not inconsistent with perfectly genuine butter. Mr. Otto Hehner and Dr. Richmond would tell them that butter undoubtedly genuine produced much lower figures. They would also have it in evidence that the butter from which the sample was taken came direct from Siberia and was not shifted at Hamburg. He would call a gentleman from Russia, who gave evidence by authority of his Government, to show the condition under which the butter was made. In winter the milk was poor and small, and butter was consequently affected. In addition, Dr. Allen, who had made experiments at the instance of the Danish Government, would tell them with regard to continental butters, and more particularly with regard to Russian and Siberian, that the standard was low. Mr. Lewin told them he had found crystals which was inconsistent with being genuine butter, but he was in a position to show that in Siberia and Russia, when butter was allowed to cool rapidly, crystals would be produced. He suggested that the percentage of margarine was very small, and in genuine butter much lower figures had been obtained. In winter time the butter fat in milk got less and less, and experiments showed that from the 7th of September to the 1st of November figures went down from 5·1 to 4·1, so the standard laid down by Mr. Lewin—4·6—was one which could not be properly fixed. He also pointed out that there was not a margarine factory in Russia where it would not cost more to make than butter itself, consequently they had a right to infer the improbability of adulteration.

Mr. Hehner, Mr. A. H. Allen (analyst for Sheffield and West Riding of Yorkshire), and others having given evidence,

Mr. MEAD thought the case was not made out, and dismissed it.

Batch of Adulteration Cases at Westminster.

SEVERAL summonses under the Food and Drugs Acts were for hearing, before Mr. SHEIL, at the instance of Inspector Perrin, on behalf of the Lambeth Borough Council.

The first was against Susannah Lewis, of Vauxhall-walk, S.E., for selling milk from which 10 per cent. of the original fat had been abstracted.

Looking at the certificate of the analyst handed up, Mr. SHEIL said he did not think it in proper order. There was nothing to show that the fat had been abstracted; it was deficient, and that might be the nature of the thing. He should dismiss the summons. His Worship added that he thought these cases should be conducted by a solicitor.

A second summons against the same defendant was for exposing margarine for sale without a proper label attached.

Looking at the section of the Act under which the proceedings were taken, Mr. Sheil said it referred only to packages, not to a tub. The defendant should have been summoned for selling margarine as butter. This summons would also be dismissed.

A similar summons against Mary Ann Jones, also of Vauxhall-walk, was dismissed on the same grounds. Mr. Perrin said he had never before had any difficulty in such cases, in which he had proceeded in the same way.

Margaret Hughes, Princess-road, Lambeth, was fined 20s. and 12s. 6d. costs for selling milk which had been adulterated with water to the extent of 6 per cent.; and William Davis was fined 20s. and 12s. 6d. costs for selling as coffee a mixture containing 50 per cent. of chicory.

THE VALUE OF CONDENSED MILK.

CONDENSED milk has been so much abused by some practitioners that it is interesting to find that in this, as in all other matters, doctors differ. Dr. Edson recently expressed himself very strongly in favour of the use of condensed milk for infants as a substitute for mother's milk. "What is wanted," he says, "is a food that is nutritious, wholesome, uniform, readily procurable, not unreasonably expensive, and that will keep fresh and sweet under all circumstances. The article that best answers all these conditions is condensed milk put up in cans and sufficiently sweetened to preserve it. This is the one point that I wish to emphasise in this instance, that in canned condensed milk we have an article that fully meets all the requirements of bottle-fed children." He says he has never heard of any series of cases where it has been used faithfully and intelligently and proved a failure. He does not regard the fact of its being sweetened as constituting any objection to it. He lays great stress upon the importance of its being sufficiently diluted and prepared fresh each time that it is wanted. For a very young infant he recommmends a teaspoonful of the milk to fifteen of water and two of lime water, with just a trace of salt. The degree of dilution may be gradually diminished after the child is three months old.

Supplement to The Sanitary Record, *June 20th*, 1901.

Food & Health

No. 53. JUNE, 1901.

PREVALENT PROCESSES OF FOOD ADULTERATION.

The principal processes of food adulteration may be classified as follows:—(1) Adulteration secured by the elimination of some valuable constituent. The most common form of this adulteration, perhaps, is the sale of skim-milk or partially-creamed milk as the genuine article. It is well known that in milking a cow the portions of the milk secured at the last are richer in fat than those secured at the beginning. Hence a cow may be partially milked and the product sold as whole milk, while the residue remaining in the udder may be subsequently extracted and masquerade as cream. Thus the very method of milking may become a means of adulteration. (2) The addition of some harmless diluent. Dairy products furnish another example of this practice, illustrated in the hoary joke of the well and the milk pail. (3) Adulteration by the subsitution of a cheaper for a dearer product. This form of adulteration is illustrated in the preparation and sale of cotton-seed oil as olive oil, of oleomargarine as butter, or of horseflesh as beef. (4) Adulteration by colouring an inferior product to resemble a superior. This is a very common form of adulteration. It is shown in the colouring of green vegetables by copper salts, as, for instance, the French peas, which are very much liked and so commonly eaten; or in the colouring of butter, giving the butter of inferior quality the tint of a superior article; or in the colouring of oleomargarine so as to resemble butter; and the colouring of preserved meats to match the natural tints. (5) Food adulteration by the addition of antiseptics. This is probably the most common of all forms of adulteration, and all perishable articles of food have become illustrations to a greater or less degree of this class.

In considering the problem relative to the influence of adulterated food products on health, it is necessary to realise the practical impossibility of defining in absolute terms the extent of the injury which may result in any given case. Food is the fundamental factor in individual and national advancement. It may be said, *cæteris paribus*, that that individual or nation is the strongest and best which is the best fed. Therefore the study of the effect of food upon the health lies at the very basis of social and economic progress. It is well to safeguard the education of children and of youth; it is important that the religious and moral influences that surround them should be carefully considered; but before this comes the necessity of nourishment. Long before the infant knows good from evil, or noun from verb, it realises the necessity of sustenance. Mistakes which are made at the beginning are difficult of correction, and therefore the character of the foods of infants and children is a problem of the first importance.

Unfortunately, or fortunately, fashionable civilised life has brought largely into discredit Nature's method of nourishing infants, and hence we have thrown upon the market a legion of so-called infants' foods, many of which are not exactly suited to the juvenile digestive functions. It may be stated with certainty that what would be considered a healthy and unadulterated food for an adult might with justice be considered an unwholesome and adulterated food for an infant.

There is, perhaps, no other subject to which the attention of the medical fraternity could be so profitably directed as to the careful study of the character of the infants' foods offered as a substitute for mothers' milk. Another point which should be taken into consideration here is that the injury produced by artificial or adulterated foods in the infant lasts probably through life, if life be continued to any length of time, or hastens the death of the child. On the other hand, the adult and healthy stomach may sustain without injury the exhibition of adulterated foods to a limited extent. Therefore it is evident that the age limit is an important factor in the study of this subject. It is plain, without argument, that infants' food should correspond as nearly as possible to the average healthy milk of the mother. Its chemical composition can be closely imitated in the artificial foods which, of course, in the case of infants should be the milk of the cow or other domesticated animal, modified to resemble, as nearly as possible, the mean composition of mothers' milk.

In the case of adulterated foods the questions which arise are extremely complicated. The healthy adult stomach can bear with impunity the exhibition of adulterants, at least for a time. It is hardly fair, however, to assume from this fact that such adulterants are harmless. Rather should we judge them from their accumulative effect—that is, the final effect which their continued use would produce. They must also be judged largely from the effect which they will have upon digestive systems disordered or weakened by disease or advancing years. In other words, the duty of the law and of the medical profession is to protect the weak and the helpless rather than the strong and independent. It is safe, therefore, to predicate this rule, viz., that that form of adulteration which by any final action upon a healthy organism or by any immediate action upon a weakened organism produces harmful effects should be prohibited. On the other hand, those forms of adulterants which are plainly indicated upon the label of the food, and therefore work no deception upon the purchaser, may be permitted, providing they do not, under the above circumstances, produce any injurious effects.

It may be well at this point to state in detail a few of the forms of adulterants which typify the above statement.

There are some forms of adulterants which are not injurious to health. In this connection may be mentioned the food product known as glucose. Glucose is a term applied to a mixture of sugars derived from starch by hydrolysis. The hydrolytic effects are produced usually by a mineral acid, as, for example, sulphuric or hydrochloric acid. Now it is perfectly evident that the hydrolysis of starch cannot produce an injurious substance except when conducted in an improper manner. In the natural process of digestion starch, which is one of the most important foods, is hydrolysed first by the saliva and finally by the secretions of the small intestine, particularly that of the pancreas. The final products are the same as those produced by artificial hydrolysis. In my opinion, therefore, well-made glucose is a whole-

THIRD EDITION. Thoroughly Revised, and brought Up to Date.

THE

FOOD INSPECTORS' HANDBOOK.

By FRANCIS VACHER,

Medical Officer of Health for the County of Cheshire.

The work has been carefully revised throughout, and a considerable number of additional pages appended, as well as several valuable illustrations, bringing it up to date in every respect. For the Sanitary Inspector and Inspector of Foods, the book in its present form will be found indispensable

THE SANITARY PUBLISHING COMPANY, LIMITED, 5, Fetter Lane, London, E.C.

some and nutritious food. When mixed with honey it is both palatable and nutritious, and this mixture is one of the most common forms of honey adulteration. Such an adulteration is to be condemned in the most unmeasured terms, but not because of the unwholesomeness of the product. If, on the other hand, glucose be manufactured with sulphuric acid containing a trace of arsenic, severe poisoning cases may result, as in the case of the beer poisoning at Manchester.

The food fats of healthy animals, such as lard and tallow, cannot be regarded as unwholesome products either when consumed in connection with other portions of the carcase or as separate foods. These fats are universally employed in our kitchen, and there is no reason for believing that when they are combined to form a pure article, as oleomargarine, they possess any unwholesome properties. The fraudulent sale of oleomargarine as butter cannot be too severely condemned, but, as is the case with glucose, not on account of unwholesomeness. The same is true of the many vegetable oils, such as the oil of cotton-seed, sunflower oil, and peanut oil, which have been largely employed as salad dressings in the place of olive oil. The adulteration of olive oil with these bodies is most reprehensible, but, again, the objections thereto cannot rest on hygienic grounds. But we are principally interested in the present instance with that other form of adulterants, which directly or indirectly, sooner or later, produce injurious effects.

Among these may be reckoned a great many of the artificial colours, such as those of copper and zinc, for preserving the green colour of vegetable foods. Many coal-tar colours are used for similar purposes, especially with animal products. A large list of such colours might be mentioned for use with fresh and preserved meats and with dairy products. Formerly white butter was coloured yellow, to resemble the more desirable varieties, by the use of a vegetable substance called annatto. Lately this vegetable colour, which by most persons is considered harmless, has been almost entirely superseded by yellow coal-tar colours; in fact, it is difficult to obtain in the open market at the present day butter which has not been artificially coloured. These coal-tar colours, when taken in considerable quantities, produce serious disturbances of the digestive organs. In the minute quantities employed it is probable that these colours are harmless, but the burden of proof rests upon those who use them; the presumption of guilt lies upon them. It is easy to extract from the quantity of butter used by a hungry man at an ordinary meal a sufficient quantity of this colouring matter to dye a large tuft of white silk a beautiful saffron. This colouring matter is absolutely indigestible, and thus it is fair to assume that when it has been absorbed into the system it is eliminated slowly and with difficulty. The colouring of butter artificially is only an excuse for poor dairying, since if milk cows be properly fed they will produce, the year round, a rich yellow cream, giving a delicious butter of the most delicate natural tint. It is unfortunate that the public taste has been so educated, or perhaps better, vitiated, in the use of artificially-coloured butter, that the more delicate tint of the natural article is a bar to its sale.

Of sixty-seven different samples of antiseptics lately examined, thirty-three contained borax or boric acid; eight were sulphites of sodium, potassium, or calcium; five contained salicylic acid or its sodium salts; four benzoic acid or its sodium salts; one was a mixture of boric and salicylic acids; one, boric acid and ammonium fluoride; three, formaldehyde; two, pyroligneous acid; one, ammonium fluoride; and one, beta-naphthol.

From the above statement it will be seen that one-half of the antiseptics offered for sale consist of borax or boric acid.

The next most abundant class of antiseptics is composed of the sulphites. Sulphurous acid is a well-known preservative, and its efficiency in this direction when combined with a base is but little diminished. The sulphites as a rule are easily soluble, and these are readily mixed with moist or liquid food products. In the form of a fine powder sulphites are easily applied to smooth surfaces such as meats, and with very happy effects in preventing decay.

By far the most objectionable of the antiseptics contained in the sixty-seven samples referred to is salicylic acid. As a preservative substance salicylic acid probably is to be preferred to any other, if its effects upon digestion are not taken into account. It is cheap, white in a powder, or colourless in solution, almost tasteless, and extremely effective as a germicide. Its use, however, even in small quantities, is to be unqualifiedly condemned. It deranges digestion, interferes with assimilation, and exercises a generally deleterious effect upon the system.

There are many other preservatives, notably saccharin and nitrate of potassium. Of these saccharin is highly objectionable, while nitrate of potassium in condimental doses may be permitted. The use of fluorin as a preservative is somewhat dangerous, and fluorides should be rigorously excluded, at least until it is demonstrated that they are harmless. The preservatives above referred to are often sold under trade names which give no clear idea of their composition. The sale of injurious substances under such fanciful names is a crime against the community, and those who engage in it ought to be adequately punished.

MILK-BORNE EPIDEMICS OF SCARLET FEVER.

Reporting on a recent outbreak of scarlet fever, in part due to an infected milk supply, Dr. George Newman, Medical Officer of Health for the district of Finsbury, refers to an objection to which his attention was called by various milk dealers:—

"The objection may be stated thus: If this milk was infected with scarlet fever, how is it that *all* the persons who purchased any of it have not contracted scarlet fever?" To this, he states, "my reply is as follows: First, the entire quantity of infected milk introduced into Finsbury was small, probably not in any case more than two milk-churns. Secondly, only a very small portion of the whole would be consumed *uncooked*. In many homes, it is satisfactory to report, milk for the children is regularly boiled. In many more instances milk is consumed not as a beverage but in milk puddings, &c. Thirdly, in order that infected milk may convey disease it must be consumed by susceptible persons. It is a well-proved fact that not all the persons coming in the way of infection contract disease. Ninety-nine insusceptible persons may come into the way of infection, one susceptible person may contract the disease."

The following suggestions regarding the control of milk supplies are also appended:—

"At present it may be said that whilst we have in operation registration of milkshops and some control over their management, there is little or no protection of the milk itself. A person buys some milk at his doorstep which comes from a small milkshop, which is supplied by a contractor, who is supplied by a large number of farmers in remote districts of the country, the purchaser, the purveyor, and the contractor all being entirely ignorant of the fact that this particular milk is derived from a farm on which an infectious disease is prevalent. I am strongly of opinion such a contractor should, in the first place, keep a register of the destination of the milkshops to which the milk from every farm with which he deals is delivered; and, in the

second place, he should only deal with farmers willing to furnish him with a written guarantee that they will inform him immediately of any outbreak of disease in man or animal upon their farms. By these two comparatively simple measures it would be possible to *trace* infection and *stop* infection at once instead of being compelled to wait until all the mischief has been done. I am, of course, aware of the protection afforded by Section 15 of the Dairies, Cowsheds, and Milkshops Order, but this does not concern the contractor.

"The custom of some purveyors of milk to obtain their daily supply from several sources is not in my judgment a desirable custom. It greatly complicates the difficulty of tracing the source of infection, as it also increases the liability of the purveyor to risk. Another circumstance which is apt to obscure the source in these cases is that the various supplies are delivered at different times and mixed together in the milkshop. Hence one delivery to purchasers may be a mixture of milk from various farms.

"The evidence obtained at this outbreak also draws fresh attention to the extreme importance of cleanly methods of purveying milk. Milk must be kept in clean vessels, which are regularly and thoroughly cleansed, and it must be protected as much as possible from dust, flies, &c. The simplest measures, if properly carried out, may be efficient and adequate."

COOKERY DE LUXE.*

This fine volume of close upon 800 pages deserves to enjoy a large circulation, for not only is it thoroughly practical, but it is conceived on sound scientific principles. Not the least valuable portion of the book is that devoted to theory and the elaboration of the general laws underlying the practice of cookery. While Mr. Senn is an enthusiast in his profession, he acknowledges that the art side must be subordinated to the scientific, and consequently he eschews the extravagantly ornamental, all over-elaboration, recognising that the aim of the cook must be to aid digestion, to facilitate assimilation. "The New Century Cookery Book" is, therefore, eminently a treatise of dietetics, a guide as safe for the plain household as for the artistic side of kitchen work. Commencing with a sensible *exposé* of the progress, aims, and objects of cookery, the author discourses of food elements and their combination, which naturally leads to notes on marketing, with most useful hints as to the choice of economical and wholesome foods. The question of fuels, the useful degrees of heat, and the chemical and mechanical changes which take place during the process of cookery are next discussed, forming an introduction to the chapter on the different processes of roasting, boiling, stewing, &c. The chapters dealing with kitchen construction and fittings will meet with the approval of all who are interested in sanitation. Coming to the practice of cookery, we note a philosophical chapter on the use of seasonings and flavourings. The chapter on soups will be found most serviceable in the kitchens of infirmaries and large public institutions, for though Mr. Senn discourses lovingly on the choicer descriptions of consommés creams, and purées, he does not neglect the cheaper forms and those required in sick rooms. There are seventeen chapters devoted to short treatises on, followed by a marvellous array of recipes for, hors d'œuvres, soups, sauces, garnishes, fish, entrées, roasts, removes, vegetables, salads, fruits, sweets, &c. A very full index and a number of good illustrations help to make this book not only an exhaustive but a practical encyclopædia of all that relates to food and its preparation for civilised man.

* "The New Century Cookery Book: Practical Gastronomy and *Recherché* Cookery." By C. Herman Senn. London: Spottiswoode and Co. Price 12s. 6d.

FOOD VALUES IN PRACTICAL LIFE.

A recent work on dietetics, by Dr. Hutchinson, has emphasised some of the facts of food values in an excellent way. The cherished notion that fish is a food for the brain worker has been consigned to oblivion, though many fish are cheap foods. Oysters are favoured among fish foods for the convalescent, but twelve oysters have not the nutriment of one egg. So, too, is the white of one egg equal in value to three teaspoonfuls of most beef extracts. "It is pathetic," says the writer, "to see poor people in cases of illness paying a large price for so very small a return."

The question of vegetarianism may almost be said to be settled by modern dietetic science. The strict vegetarian, to obtain a living wage of tissue-formers, must almost fill his stomach to its utmost limit three times a day. It means a low standard of life, and weak resistance to disease. It is not without reason the more energetic races of the world have been meat eaters.

Alcohol in moderation is considered by this author to be a valuable aid in the running of the human machine. It is used up in the body; it is a food, and spares the combustion of fat. If, however it exceeds the quantity taken to act as a food, it acts as a poison, and the percentage of waste rises. Alluding to "three-bottle men," the author says: "One is tempted to think that the power of our tissue to oxidise alcohol has actually undergone a decline." The notion that "fusel oil" is the deleterious agent in poor whiskey is exploded, though a volatile oil is suspected. Dr. Hutchinson is a firm believer in bottled stout, and considers it the model soporific. "It is far better than opium," he says, "and produces more nearly natural sleep."

MILK SUPPLIES FROM TUBERCULOUS COWS.*

By Dr. E. G. Annis, Medical Officer of Health, Borough of Huddersfield.

The recent Order of the Local Government Board, which has added tubercular disease of the udder to the class of diseases of cattle included in the Dairies, Cowsheds, and Milkshops Order of 1885, has enabled us to take certain steps to check the distribution of milk from milch cattle with diseased udders, but at the same time more drastic powers are still needed, for the Order states that milk from such like affected cattle (*a*) shall not be mixed with other milk; (*b*) shall not be sold or used for human food; (*c*) shall not be sold or used for swine or other animals unless and until it has been boiled.

These prohibitions on the face of them appear satisfactory and sufficient, but it is in their practical application that the difficulty arises, for when a case of diseased udder is found out, the Medical Officer of Health visits the premises and informs the owner of these requirements. Sometimes a promise is obtained that such will be carried out; at other times no definite promise is given. Whether, however, the promise is made or not, the matter is entirely in the hands of the cowkeeper, because unless one is able to have an Inspector practically upon the premises day and night continuously to see the affected animal milked, and the milk effectually dealt with, one cannot be absolutely certain that the requirements of the Order are carried out, and, of course, it will be seen from this that the difficulty is very great. Unfortunately, some milch cattle with tubercular disease of the udder are in the habit of giving a large amount of milk, and this large quantity proves a source of great temptation to some cowkeepers.

* Annual Report, 1900.

The further measures needed appear to be somewhat on the lines in force in reference to other material found unfit for human food, whereby seizure of the animal giving such milk could be made, the animal killed under supervision, and the carcase properly dealt with; of course, should any error be found to have been made, full compensation to be allowed. As an illustration of the above difficulties, I might mention that the Veterinary Inspector, in the course of his regular and systematic inspection of the cattle, found and notified to me a case of tuberculosis of the udder in an animal belonging to a registered cowkeeper. A sample of the milk was obtained and submitted to bacteriological examination, when tubercle bacilli were found to be present in considerable amount. I visited the cowshed, and interviewed the owner of the animal, informing him of the requirements respecting the milk, and strongly advising that the animal should be slaughtered under supervision, and its carcase properly dealt with, and for that purpose that the owner should notify me of the place and time of such slaughter, so that I might be present to inspect the carcase. This he promised faithfully to do. In the course of a week or ten days I heard from another source that the animal had been taken to a neighbouring market and sold to another milkman without any disclosure as to its condition being made, accordingly the distribution of this poisonous milk would still go on without let or hindrance, at any rate for a time, in some other place.

HOW COOKING POWDERS ARE "COOKED."

Some revelations made in a recent report by Dr. Alfred Hill, Birmingham City Analyst, in regard to the adulteration of baking powder, egg powder, and custard powder are worthy of note. The report states :—

BAKING POWDER.

Of nineteen samples six contained alum, and the vendors were prosecuted for the sale of an article injurious to health. For a number of years baking powder was regarded as food, and convictions were obtained for the sale of adulterated articles. In 1894 the Judges of the Court of Queen's Bench decided in the appeal case, James *v.* Jones, that baking powder was not an article of food in the meaning of the Sale of Food and Drugs Acts, and so prevented any further samples being taken. The Act passed last year extended the definition of "food," so as to include "any article which ordinarily enters into or is used in the composition or preparation of human food," and, therefore, baking powder is again legally a "food." The necessity of this action is shown by the large proportion of the samples containing the very objectionable ingredient alum.

The thirteen samples free from alum had been prepared from bicarbonate of soda, tartaric acid, and rice flour. Some of them had not been kept perfectly dry, and contained tartrate of soda produced by the reaction of the first two ingredients. A baking powder should consist of harmless materials, which, on the addition of water, will evolve carbonic acid gas, with sufficient starchy material to prevent premature decomposition. The efficiency of a baking powder will be proportionate to the amount of this gas produced by adding water to it. In these powders this varied from 1 to 9 per cent., while the rice flour varied from 52 to 81 per cent. The tartaric acid and the bicarbonate of soda should be present in the proportion of one of the former to 1·12 of the latter. In these samples the proportions varied from practically equal weights, to one part of tartaric acid to twelve of sodium bicarbonate, the latter being nearly all bicarbonate of soda. The raising power of the five samples containing over 80 per cent. of rice flour would be very slight, and their sale is very nearly, if not quite, a fraud on the public, but unfortunately there is no standard of composition, and I did not feel justified in certifying them as adulterated.

The other six samples were adulterated with alum, and contained from 13 to 35 per cent. of this objectionable ingredient. Five of them did not yield more than 4 per cent. of carbonic acid gas, so that besides containing alum they were deficient in raising power.

One sample was marked "Prize Medal Baking Powder," and another actually claimed to make bread more digestible, in spite of the presence of 25 per cent. of alum. It bore the following impudent label :—"By the use of this preparation, as the saccharine properties of the flour, which are destroyed by fermentation with yeast, are preserved, the bread is more nutritive, and a larger quantity is obtained from the same weight of flour. Bread made with yeast, if eaten before it becomes stale, ferments again in the stomach—producing indigestion and numerous other complaints; when made with this powder it is free from all such injurious effects. The powder is equally valuable in making puddings and pastry, which it deprives of all their indigestible properties."

EGG POWDER.

Fifteen samples of egg powder were taken, and all were free from alum. An unprejudiced person would expect that a preparation known as egg powder was either prepared from eggs or that it was of a similar composition to and a suitable substitute for them. This opinion would be supported by such labels as the following :—"Egg powder is a first-class substitute for eggs." One made the following claims :—"Concentrated egg power. A complete substitute for, but not made from eggs. This valuable preparation is a complete substitute for eggs in the making of all sorts of cakes, &c., to which it imparts the lightness, richness, appearance, and flavour of new-laid eggs."

Eggs are chiefly used in cookery for two purposes, to produce richness and lightness. The richness is due to the fact that an egg contains rather more than 100 grains of nitrogenous food, such as albumen, &c., and a similar quantity of fat. The glairy albumen of the egg when beaten up encloses a considerable quantity of air, and the gradual escape of this air during cooking produces lightness.

These samples of egg powder were practically nothing but baking powder coloured with turmeric or a coal-tar dye. Several of them had very little raising power, yielding less than 1 per cent. of carbonic acid gas on wetting. The "richness" imparted by them is confined to the small amounts of nitrogenous matter and fat contained in the rice or maize flour of which they are composed, though the colouring matter present might produce the appearance of richness. In short, these powders may impart lightness, but the "richness" will be less than that of an equal weight of ordinary flour. The labels quoted were distinct, if not fraudulent misrepresentations, but the absence of a standard prevents an analyst classing them as adulterated. Two samples bore fairly honest labels as follows :—"Egg powder. Not made from eggs. This valuable preparation may be used with great advantage in the making of all sorts of cakes, &c., to which it imparts all the lightness of eggs."

CUSTARD POWDER.

All the samples of custard powder, six in number, were free from alum. They were composed of maize or arrowroot with a small quantity of mineral matter, and coloured with turmeric or a coal-tar dye. Custards are prepared with eggs and milk, and form a nutritious article of diet, particularly for invalids. "Custards"

made with these powders would be no more nutritious than milk thickened with arrowroot or cornflour, and the difference in nutritive power might be serious in cases of illness. Again, large claims are made on the labels. One is marked:—"Custard powder makes the richest custards without eggs at half the cost and trouble." The label of another had the following observation:—"Custards made with this powder are considered by the medical profession to be more nutritious and lighter of digestion than any kind of meat, and are being strongly recommended by the most eminent medical men as a beneficial food for supper, and for invalids there is nothing to equal them."

If these samples had been certified as adulterated, the "custom of the trade" would be largely brought up to prove that custard powders always were so prepared, and a conviction would be impossible, but one strongly feels that deceptive labels such as the preceding should be prohibited.

TUBERCLE BACILLI IN BUTTER AND MARGARINE.

Markl (*Wiener Klin. Woch.*, No 10, 1901) states that during the past five years many investigators have found virulent tubercle bacilli in market butter. The question is, what percentage of market butter contains bacilli, and what is the danger from eating butter? Investigators differ widely in different localities, so the author made experiments with the market butter of Vienna. He used the Obermueller method, injecting the centrifugated melted butter into the abdominal cavity of animals. In all he innoculated forty-five guinea pigs, and not one died of true tuberculosis or showed signs of the disease; one case proved to be pseudo-tuberculosis. Ten animals died of peritonitis, but none injected with margarine died from peritonitis. In the case of pseudo-tuberculosis he found a long acid bacillus taking Gram's stain, and which he considers the cause of pseudo-tuberculosis as well as Petri's and Hormann Morgenroth's bacilli.

BRITISH CONGRESS ON TUBERCULOSIS.

We hear that the arrangements for the above Congress are not only in a very forward state in this country, but that active measures are being taken abroad to secure a large number of Continental visitors. The German Committee will be presided over by his Serene Highness the Duke of Ratibor.

In Paris a French Committee has been formed under the presidency of Prof. Brouardel, with Dr. Thoinot as honorary secretary, assisted by Drs. Horny, Sersiron, and Dumarest. This commitee has sent out a special circular to members of the profession and others who are particularly interested in the question of tuberculosis.

Amongst those who have already inscribed themselves are the Prince d'Arenberg, Profs. Brouardel, Lannelongue, Proust, and Nocard, and Drs. Martin, Léon-Petit, Sahran, Letulle, and Hérard.

Prof. Julian Colleja, President of the next International Congress in Madrid, one of the Vice-presidents from Spain, is also exerting himself to promote the interests of the cause.

Profs. von Schrotter, Weichselbaum, and others, have likewise joined from Austria. Amongst the representatives from America will be Professors Osler and Janaway, while numerous adhesions have been received from Hungary, Italy, Belgium, Norway, and Sweden, Holland, Switzerland, Portugal, and Egypt.

CANADA AS A SOURCE OF FOOD SUPPLY.

The Canadian Minister of Agriculture, the Hon. Sydney Fisher, is at present paying a visit to this country. In conjunction with Professor Robertson, the Government expert, he is looking out for some pure-bred stock for introduction on to the great experimental farms of the Dominion. In the course of conversation with a representative of the *Daily News*, Mr. Fisher gave some noteworthy details anent the possibilities of Canada as a producer of food supplies, claiming that his country has now advanced to be one of the greatest food-producing regions of the world.

Mr. Fisher is of middle age, very quiet and unassuming in manner, but a typical man for the responsible position he holds. He entered the Dominion Parliament as a staunch Liberal in 1882, and since the accession of his party to power in 1896 has held his present post in the Government. His school and University life was in England; he is a graduate of Cambridge, and has himself been a successful farmer on a large scale for many years in Canada. His practical experience and his position as one of the temperance leaders in the Dominion have given him a firm place in the confidence and affection of the farming community.

So much are we in the habit in this country of regarding Canada as a cold, bleak country, rather too near to Klondyke to be quite comfortable, that it is difficult to realise that the southern border of Canada is as far south as the shores of the Mediterranean.

It is an ideal food-producing region, with abundant rainfall, hot summer, a dry, cold winter, and a soil with the garnered fertility of untold ages.

In five years its export to this country of dairy products, grain, fruit, and meat has grown from 7 per cent. to 16 per cent. of our total imports. At this rate, in another dozen years Canada alone could provide our whole food imports.

But as cultivation and civilisation spread their borders, many of the difficulties of the farmer increase. One of the most curious changes is the spread of the bacteria of decay. Six years ago the virgin fields of the great North-West were almost in the condition of Mars as depicted by Mr. H. G. Wells—void of microbes. In the hottest summer weather the dairy farmer could keep his milk sweet for a week. Now, with the most elaborate cleanliness, he is lucky if it will keep more than a couple of days, and the journey to the butter or cheese factory must be made at least twice as often. Weeds and insect pests also follow the plough, and every year more science and forethought and organisation are needed.

With pardonable pride Mr. Fisher told me some of the good things done by his department to help the sturdy farmer-folk of the Dominion. While here the Government makes believe to help the distressed agriculturist by doles, in Canada the State helps the farmer by training his intelligence, by showing him, in four great experimental farms under different climatic conditions, what can be done, and how to do it; by collecting information and organising transit in a way that no individual effort could emulate.

"Our principle is," said Mr. Fisher, "that it is the business of the Government to take first risks. Where an experiment must be made, the Government bears the cost of it, and all alike reap the benefit. To give a case in point. Fifteen years ago, in one district the farmers discovered the benefit of co-operative dairying. The thing was an obvious success, but it would have taken generations for the plan to spread across the thousands of miles of Canada. The Government took the matter in hand, established model co-operative dairies throughout the country, and now the farmers everywhere have taken up the system, and in fifteen years a change has

been accomplished which would otherwise have taken half a century."

Not only does the Canadian Government teach its farmers how to grow, but how to get to market. Whenever there is a probability of a paying trade, it guarantees the cost of cold storage cars for dairy produce sent to the coast.

It has succeeded at small expense in inducing numbers of great steamship companies to provide refrigerating plant for bringing produce to this country, and is now carrying on an experiment by which fruit will be brought over this year in cool-air chambers, like those just adopted for the Jamaican banana trade.

Agents in the ports in this country watch the unpacking and condition of every ship load of produce, and report to Canada. Self-registering thermometers under seal are placed in every ship before leaving Canada, and the diagrams showing the temperature of the cargo throughout the voyage are posted back to the Dominion authorities. The produce is watched to its destination, and every care is taken that the Canadian farmer shall not suffer in reputation through ill-handling in transit.

While doing all this for the farmer, the Government is careful that the reputation of Canada shall not suffer by any malpractices among its own people. The production of margarine, or of cheese artificially "filled" with foreign fats, is prohibited by law, and there are stringent regulations as to fair and honest packing and branding of all goods.

As I listened to this story of national power and organised effort expended in the production of wholesome food for the maintenance of life, I could not help mentally comparing it with the pouring out of blood and treasure nearer home for the purposes of destruction.

There is an old story how Jove, pitying a great king robbed of his subjects by plague, gave him a new and victorious army by turning ants into men. Even so does the Government of Canada raise legions of tiny warriors from the soil to help the farmer against his myriad enemies. Those birds and insects which make war on destructive pests are studied and commended to the farmer's protection; bacteria which promote plant life and help to conserve moisture in the soil are cultivated; boys and girls at school are trained to pick out from corn the grains which will be most reproductive as seed. A periodical circular telling all about science and markets is posted to fifty thousand farmers.

When I add that, by a curious survival from more leisurely days, the Canadian Minister of Agriculture deals with statistics, the census, copyrights, patents, trade marks, and a dozen other things, your readers will wonder how Mr. Fisher found time to talk to me at all.

CASES IN COURT.

[RECORDS of Police-court proceedings for insertion in the "Food and Health" Supplement should reach us not later than the 10th of the month. Generally speaking, they should be as brief as possible, but where any important point of law is involved a fairly full report is permissible.—ED. S. R.]

Heavy Fine for Milk Adulteration.

IN Glasgow Sheriff Court, William Anderson, Braehead Farm, East Kilbride, was fined £60, including £7 11s. 8d. of expenses, for having forwarded to Glasgow for human consumption four butts of sweet milk and two butts of skim milk which contained added water. In the case of the sweet milk, the adulteration was 10, 12, 14, and 16 per cent. respectively, and in the case of the skim milk 5 and 9 per cent. The destination of the milk was the Glasgow Co-operative Society. It was the accused's second offence.

Unsound Fish at Darlington.

AT Darlington Borough Police-court, Chas. Harris, fish dealer, Bondgate, Darlington, was charged under the Public Health Act with selling unsound fish in the Darlington open market on June 1st.

Inspector Atkinson and Sergeant Jameson gave evidence as to the exposure of 8½ lb. of fish for sale on defendant's stall, which they stated was unfit for human consumption, and which the Medical Officer and a magistrate had ordered to be destroyed. The police-officer stated that it had been offered for sale at 3d. per lb.

Defendant and his employé said the fish had been taken to the market in mistake, and was put on one side.

The BENCH imposed a fine of £5, remarking that the poorer classes must be protected.

Bad Meat at Finsbury.

AT Clerkenwell Police-court Wm. Kendall, butcher and sausage maker, of 93, Chapel-street, Finsbury, was summoned for depositing for sale on 28th May, at his premises, 92 lb. of beef and pork, 4 lb. of sausages, nine pigs' plucks, and five bullocks' livers, which were unsound and unfit for the food of man.

Mr. RICKETTS, solicitor, prosecuted on behalf of the Finsbury Borough Council, and Mr. TRAVERS HUMPHREYS defended.

Inspector Billing proved the seizure of the meat,

Has the Charm of being always Nice, and it is also an excellent Digestive.

A Free Sample.—A Voucher for a Dainty Small Hovis Loaf will be gladly sent on request. — The HOVIS COMPANY, Ltd., Macclesfield.

which was subsequently condemned by the magistrate at Clerkenwell Police-court.

Dr. Newman, Medical Officer of Health, said he inspected the meat on May 28th. It was decomposed and quite unfit for human consumption. He saw the defendant, who stated that he had eaten some of the meat cut from that which had been seized, and with the exception of the livers he was of opinion that it was perfectly good.

For the defence it was urged that owing to the hot weather the meat had turned. It was seized in the early morning of Whit Tuesday, and had been in the shop since the previous Saturday. The inspector's visit occurred before the stock in the shop had been overhauled. The defendant had been in business in Chapel-street for eighteen years, and had the reputation for selling good meat.

Mr. Bros inflicted a fine of £50 and £5 5s. costs.

Gregory's Powder.

Taylor's Drug Company (Limited), of Leeds and High Holborn, appeared, before Mr. Fordham, by Mr. Yardley Tilley, solicitor, to answer a summons taken out by the Islington Borough Council, charging them with selling at their Holloway branch Gregory's powder which did not contain the ingredients specified in the British Pharmacopœia.

Mr. Bramall prosecuted for the Council.

Dr. Teed said that the bulk of the powder consisted of hydrated carbonate of magnesia instead of pure magnesia.

Mr. Tilley, in pleading guilty, said that when it was discovered that a mistake had been made a letter was sent to all the branches of the firm requesting the managers to stop the sale of the powder, but the article at this particular shop appeared to have been overlooked.

Mr. Fordham: What is the date of the letter?

Mr. Tilley: The letter was written in 1899.

Mr. Fordham: This may be a drug which improves with keeping.

Mr. Tilley urged that the company had done all they could, but Mr. Fordham said it seemed to him to be a deliberate fraud on persons who bought Gregory's powder. In this case he was dealing with a large concern which as far back as 1899 discovered that they were using an improper Gregory powder and took ineffectual means to stop the sale. He fined the company £10, with £3 3s. costs. "The public must be protected," added the magistrate.

THE CONSTRUCTION OF FOOTPATHS.

Now ready. Price Sixpence net. With Illustrations, Diagrams, &c.

Footpaths: Their Maintenance, Construction, and Cost.

By A. TAYLOR ALLEN, C.E.,
Engineer and Surveyor, Portslade-on-Sea.

PRESS NOTICES.

There is a wonderful amount of information of one sort and another contained in the thirty odd pages of this small volume. First one reads of the laws relating to footpaths, and the cleansing, &c., of pavements; and then the different kinds of pavement are reviewed, and the cost of these given. To the special class for whom it is intended this book will, without doubt, prove of value, and many another will be glad to have a book containing the information which this gives.—*The Engineer.*

This little sixpenny book should be in the hands of every Municipal Engineer, Surveyor, and Architect.—*The Building News.*
